Brandes Wireless Headsets

The "SUPERIOR" Type

The most popular headset on the market. Better than many costing much more.

Resistance, 2000 ohms; Headbands, german silver; Cords, 6 ft. long; Earcaps, hard rubber.

Price, complete, Five Dollars

¶ Made in the same factory and with the same care as our more expensive types.

Send stamp for our catalogue "E," fully describing all our headsets.

C. BRANDES, Inc., Wireless Receiver Specialists

32 UNION SQUARE, EAST, NEW YORK

WIRELESS BLUE BOOK

Who's Calling?—You always know if you have a Wireless Blue Book on hand. Has alphabetically arranged list of all call letters of U. S. and American Wireless Telegraph Stations, Merchant Vessels, Vessels of the U. S. Navy, Revenue Cutters and Licensed and Unlicensed Amateur Stations and their location corrected to August 1, 1914. The most complete book of its kind ever published and one you cannot afford to be without. Size 6x8 inches, paper bound, with map of United States showing all principal radio stations, both government and commercial. Sent prepaid on receipt of 15c. Send now so that you can tell who is calling and being called.

Music In Colors

WHEN we go to the theater we have all probably noticed the wonderful effect that different colors play on the total effect produced on us by a certain stage setting or musical number.

A new device has been tried recently in Carnegie Hall at New York to give "color music," as it may be termed (see Fig. 1), and a special piece of music was prepared for this device by the composer, Scriabine, and produced as part of the piece, "Prometheus."

The "color organ" instrument has a keyboard of 12 colors, red, rosy-orange, yellow, green, pearly blue, "the shimmer of moonshine," bright blue, violet, purple, steely, "steely with the glint of metal" and dark red.

The composer's dream was to build a palatial theater so contrived that the audience should be bathed in rhythmical light as it listened to the music.

Modest Altschuler, conductor for the Russian Symphony Society, described the effect of the color music on the new instrument as "intoxicating," and said that if the instrument proved to be a valuable accompaniment to an orchestra, scores for it could be written so that it could be used for other pieces.

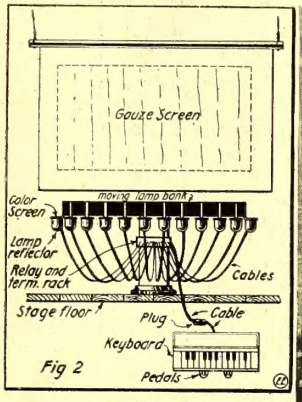

Fig. 1. As Various Notes and Chords Are Played Corresponding Colors Are Projected Upward Through Gauze Screens as Shown. Color Organ is Controlled by Keyboard and Pianist at Right. Fig. 2 Shows Details.

Note musician playing color music keyboard at right.

Simply described, the musical color scheme is worked out as follows: For every changing mood in the music a different color is taken, as given for a certain note, etc., and which color also represents as near as possible the feeling of the soul, so to speak.

We show diagrammatically at Fig. 2 how this light effect is managed. This device was built on short notice under the guidance of Preston S. Miller, of the Electrical Testing Laboratories, New York, and therefore future installations may be wonderfully improved. Referring to the diagram, a continuous band of high power tungsten lamps are caused to move half way around the belt circuit, and back again continuously; as long as the *color notes* are being used.

Flexible insulated cables connect to each lamp as seen, and over each tungsten lamp is fitted a color screen.

Over this "color organ" is placed a frame about 12 by 15 feet at the front opening. In this frame are placed several pieces of various kinds of fine transparent gauze, which hang slightly in folds. This scheme, combined with the always moving and intermixing bands of color as projected upward, forms a wonderful effect.

The keyboard, which is similar to a piano, can be played by any pianist, the musical score being written in regular notes on ruled paper, the same as any music. Color intensity variation is obtained by means of two foot pedals at the base of the keyboard. Hence the wonderful range of colors and tints possible is evident.

In laying out this musical color scheme the composer of "Prometheus" made use of an arbitrary color scale, as might be suspected. Rimington had previously worked out an equivalent system for this purpose, but the new arrangement was as follows, the tone notes being:

C ..... Red.
D ..... Yellow.
E .....Pearly Blue.
F-sharp ..... Blue
A ..... Green.
B-flat .....Steely Gray.

And so on. Various combinations of these colors were made easily possible by the keyboard, which resembled piano keys, and thus it was easy for the player to strike a chord, the same as in ordinary music.

The operation of the keys and lamps is not direct but indirect, to avoid handling any heavy currents at the keyboard. The keys when depressed close a direct-current circuit through corresponding relays mounted on the central supporting column, shown in the diagram, Fig. 2. The foot pedals control the intensity of the light and operate an adjustable impedance coil in the 110-volt alternating-current circuit feeding the moving tungsten lamp band.

The lamps were all specially made with concentrated filaments to project the maximum amount of light upward through and on the gauze screens. The lamps were made up for this work through the courtesy of the General Electric Co. The necessary color screens were placed in slides over each lamp reflector, and colored gelatine was largedly used for this work, placing it between two clear glass plates. For such colors as red, a plain red glass was used.

The great success of the effect produced with this device was due in great part to the ingenious arrangement of the gauze screens. The most flimsy screens came first, then next heavier gauze, etc., ending up with a rather stiff and coarse mesh netting. The color effect on the audience was quite marvelous indeed, as the different, always-changing colors were really seen through each other.

"The Electrical Experimenter" is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is 50 cents a year in U. S. and possessions. Canada and foreign countries 75 cents a year. U. S. coin as well as U. S. stamps accepted (no foreign coin or stamps). Single copies 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of the Experimenter Publishing Co., Inc.

If you change your address notify us promptly, in order that copies are not miscarried or lost.

All communications and contributions to this journal must be addressed to: Editor, "The Electrical Experimenter," 233 Fulton Street, New York. We cannot return unaccepted contributions unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

Entered as second-class matter at the New York Post Office, March 1, 1915, under Act of Congress of March 3, 1879. Title registered U. S. Patent Office. Copyright 1915 by E. P. Co., Inc., New York. Baron Münchhausen's New Scientific Adventures

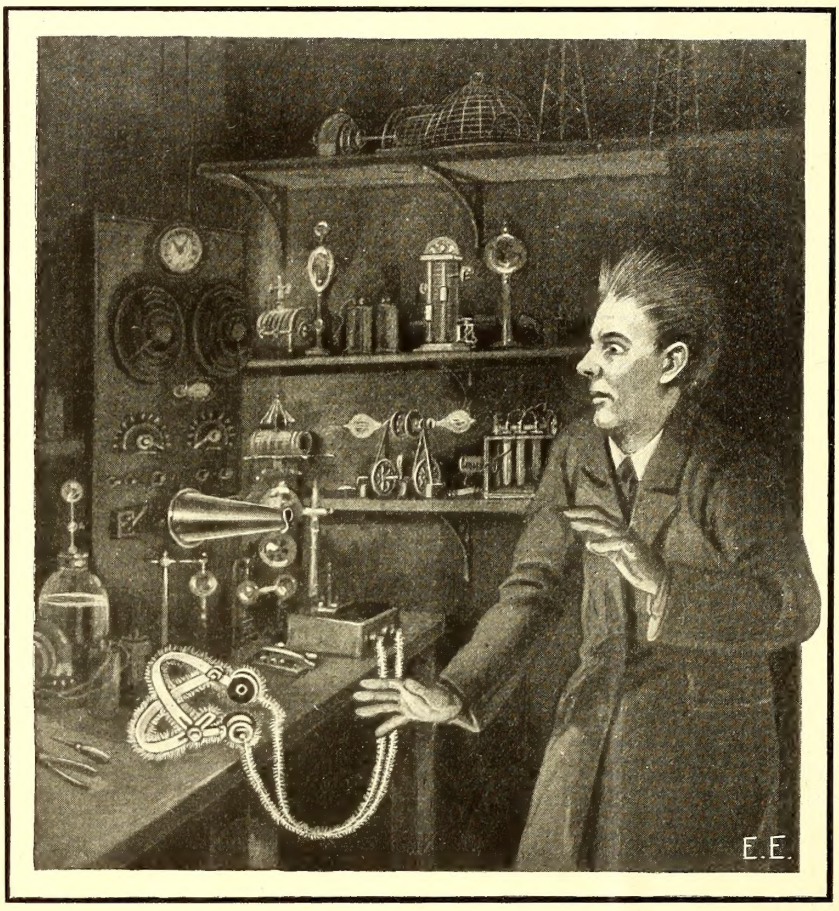
By Hugo Gernsback

I Make a Wireless Acquaintance

MY name is Ignaz Montmorency Alier. If that don't suit you I suggest I. M. Alier for short. I am a Yankee by birth; no doubt you guessed that much. Both my father and mother came over on the Mayflower and settled in Yankton, Mass., where they are engaged at present in cactus and ostrich farming. Ever since I was a little boy my father, for reasons best known to himself, begged of me to be a worshipper of truth, no matter how painful it might prove. I am glad to say that my father's teachings fell on fertile territory. I have never knowingly uttered an untruth. The pursuit of truth since I have grown up has become a mania with me, so much so, in fact, that even an every-day exaggeration made by best of friends drive me frantic. understand my liar peculiar state of mind, as far as truth is concerned, it will probably be best understood by the average layman if I say that truth with me is nothing less and nothing more but a hobby—a sort of sport, if you wish. I collect truthful statements as you would collect stamps. Particularly beautiful and original examples of truth are written down by me on large white cards. These cards are all indexed and classified and kept, vertically filed in card drawers. The originator (may I say inventor?) of these truths is, of course, given full credit on these cards, so that it is easy to find in years gone by who made this or that particular truthful statement. You will not think me immodest if I state in passing that nine-tenths of the cards contain my own name as originator of original and surprising truths. Of course, as truth is a science with me, such a statement cannot cause much surprise; I realize this fully.

I would not think of taking up your valuable time with the above statement were it not so vitally necessary for me to fully acquaint you with my character, for reasons which will be more apparent later. For this reason I also find it quite necessary to give you the following references; any of the below mentioned individuals and institutions will be only too glad to vouch for my integrity, honesty, as well as veracity.* I could give almost an indefinite list, but I prefer mentioning only the following:

Hiram O'Rourke, lawyer, Yankton, Mass.
(The above defended me in three breach of promise suits, as well as eight perjury charges of which I was accused.)



Patrick Flanagan, jailkeeper, Yankton, Mass.

Jeremiah Addlecock, jailkeeper, Coffeeville, Me.

Mike Whiffeltree, jailkeeper, Lyreville, Vt.
(The latter only knew me intimately for five months.)

The Ananias Club, Yankton, Mass.

Now that I have thoroughly established my standing I will proceed, and I sincerely hope and trust that no one will question any statements I may be called to make in these pages. They are the bare, unvarnished truth in each and every case. If called upon I will cheerfully swear to the truth of any of my statements before a notary. (I am a notary myself.)

* * * the Receivers Suddenly Became Enveloped in a Scarlet Phosphorescence, Glowing Softly Like the Light in an X-Ray Tube.

As every resident of my home town knows, I own the largest wireless plant in the State. I own the only long distance wireless telephone station in the country. As is known, I hold the long distance wireless telephone record of the world. Already in 1900, when my set was not nearly as perfected as it is to-day, I could talk around the world and converse freely with myself, the message traveling clear around the globe. This fact was described at length in "The London Scientific Gazette of 1900." (See Vol. XX, No. 19, page 39.) It attracted much attention at the time, but it was declared commercially impractical, for the reason that it was argued; if it is necessary to build a giant wireless station at a tremendous expense in order to talk clear around the globe, for the sole purpose of listening to one's own voice, why not talk to yourself without the expensive wireless? My critics contended that it would be far less expensive and perhaps more satisfactory.

Of course, this argument, quite logical as it was, for the time being discouraged me not a little, but soon I took up my studies anew and made many important new discoveries.

As president and founder of the now defunct *American Wireless Mouse Trap Co.* I learned a lot about rats and mice and this knowledge even to-day is of high importance to me.

The above company, as will be remembered by many, operated at one time no less than 80,169,509 wireless mouse traps all over the country. If we had not been so eminently successful in killing every mouse and rat in the country the company would, no doubt, be still in business. As it is, the American public calls me its greatest living benefactor for ridding the country of these pests, and this alone is honor enough and cannot but speak well for me. For the benefit of my young readers who never saw one of my wireless mouse traps let me give a brief description of same.

Each trap was constructed like a squirrel cage. The opening to the cage was fashioned in such a manner that a mouse or rat could get in it, but not out of it of its own accord once in it. Now, as anyone can readily convince himself by trial, mice and rats are exceedingly fond of revolving cages. They will travel for miles to get one. It has a most powerful fascination for them. They simply adore it and go wild about it. I am almost tempted to say that they go crazy about it, for they find it extremely hard to stop once they start running. Upon this great natural law I based my invention.

The shaft of the cage was connected to a little dynamo, which was operated at high speed as soon as the mouse or rat started the cage revolving. The dynamo in turn was connected to a little wireless set and this in turn to an aerial wire system on the roof of the house. The wireless set was constructed in such a manner that when operated it would send out a call similar to a Western Union call box. In each locality we had a wireless "central" with operators. As soon as one of the operators received a call he would look up his call book and see where the call originated. This took but a few seconds. A man would then be dispatched immediately to the house in question, where he would brain the mouse or rat on the spot, single handed, by means of a club. He would next reset the trap and return to headquarters, giving a full itemized report of the case. To the inexperienced my system of killing the rodents might appear rather long winded and expensive, but it is here where my in-

*On account of the numerous inquiries received concerning me I suggest to enclose a 2-ct. stamp for your reply when writing.

sight into human nature came to its full bloom and made me famous.

Not everybody likes to kill rats and mice. This is particularly true of the feminine humans inhabitating this globe. Why this should be so I do not profess to know absolutely, although I have some vague opinions on the subject, which, however, I would rather keep to myself. Suffice it to say, bipeds in skirts rather employ their time otherwise than catching, not to mention, killing rats and mice. What, therefore, I ask was more natural for me than to employ professional ratters and mousers, to perform the disagreeable tasks? At any event, you may be sure, the company was a huge success and many a fair damsel even to-day sends me highly perfumed letters hailing me as the liberator of the fairer sex's arch-enemies.

But this brings me away from my story. As I said already, I own the largest wireless telephone station in the country. It is exceedingly well appointed and contains instruments and apparatus of which the greatest living scientists have as yet not the faintest knowledge.

This story starts on a bitter cold December night. I could go to some length by writing two or three columns at two cents a word, stating how the wind sang weirdly through my aerial wires on the roof; how the flames of my log fire cast fantastic shadows about the room; how my cat was softly purring on a chair near by, dreaming of some long departed appetizing canary; how the windows rattled uncannily in the storm; how the trees moaned plaintively outside, and so forth. Thus I could set the scene and prepare you for the story—getting you under tension, as the editor calls it technically.

As a plain matter of fact, however, the aerial wires were full of sleet and therefore could not "sing," furthermore I was glad that they didn't come down, which would have made some music, although not very pleasant music. Then the log fire, too, could not very well have cast fantastic shadows either, nor any other shadows for that matter, because the log fire happened to be a radiator. Instead of casting fantastic shadows, however, it cast a lot of . ink noise about and every now and then made me jump clean out of my chair. Then, also, the cat could not have purred very readily on the chair because it wasn't a cat at all, but a dog to begin with, and he could not have purred even if he had taken lessons at $5 an hour. There were, however, good reason for this, too. Firstly, it was not a he; it was a she. Secondly, she had been dead for two years and only because she was stuffed so nicely did I keep her. Thirdly, she could positively not have sat on a chair near by, simply because there was only one chair in the place and I was on it. Fourthly, dogs, especially dead dogs, are not known to dream about appetizing canary birds. Then, too, the windows could not have rattled in the storm where I was, for my wireless station is in the cellar and that cellar has no windows whatsoever. As for the trees moaning or not moaning I explained above that my people were engaged in cactus farming. There are no trees on the farm, and cactus does positively not moan in a storm. It squeaks.

Now that you understand the situation fully I will proceed. It was after 12 o'clock midnight on a cold winter night. My new, loud talking telephone receivers were on my head and I had just lit a fresh pipe. I had been flirting with my vario-selective coupling-balance which was adjusted to a very long wave length—96,000 meters, if my memory serves me right—and I was just in the act of tuning down to the wave length of *F. L.*—that's the Paris Eiffel Tower—when suddenly I heard a peculiar sound. Through my receivers came a very faint, but exceedingly high pitched screaming sound, which became louder and louder each second. While I was still wondering what this unearthly sound could be, I suddenly heard in a faint but clear voice:

"Alier, Yankton, Mass.—80,000 meters." This sentence was repeated several times. I lost no time in starting my 200 K. W. generator, tuned up to 80,000 meters, and yelled into the transmitter in front of me.

"Ship ahoy! This is Alier of Yankton, who's there?" Almost instantly it came:

"It is I, Hieronymus Karl Friedrich Baron Münchhausen . . . ."

At that I almost swallowed my pipe, but just the same, the colossal nerve of that fellow aggravated me.

"You confounded liar, stop your joking," I yelled back, "if you have to say anything, say it and be quick about it, for I am going to bed in a few minutes."

"My son," it came back in sepulchral tones, "I am not at all surprised at your astonishment. Rest assured I expected you would doubt my identify. However, I have proofs. It is now 12.50 a. m. terrestrial time. Kindly mount to the top of your roof. You will find it to be a clear night, the moon being half full. Take your watch along and observe the moon carefully. Precisely at 1 a. m. I will illuminate the dark half portion of the moon with a red phosphorescence, three times beginning 1 a. m., each illumination to last five seconds with a 10 second interval between each illumination. After this return to your phones. I have spoken. . . ."

The peculiar high pitched screaming sound was heard once more in my receivers. It ran rapidly down the scale, became fainter and fainter—there was a low click in my 'phones and everything was quiet.

I must have sat dumbfounded for at least a minute before I could recollect my senses. I took the 'phones off my head and wiped off the perspiration mechanically. I am sure I was dazed. I looked at my hands, moving them back and forth before my eyes, but I wasn't certain then that I was awake. So I took a pin laying near by and shoved it in my thigh. I knew then that I really was awake. I wanted to think, but I had to laugh outright. Why, the thing was preposterous. Some practical amateur joker, no doubt, who tried to get me on the roof and then afterward have me the laughing stock of the town.

"Good stunt! Rather novel idea, ha, ha! . . . But that sepulchral, earnest voice, that distinct accent, the peculiar intonation . . . could it?" . . .

My eyes fell on the clock before me. It was 12:55. At that very moment my 'phones emitted a loud crackling sound, like "static" before a thunderstorm. As I was looking on wondering, the receivers suddenly became enveloped in a scarlet phosphorescence, glowing softly like the light in an X-ray tube.

I know now that my hair must have raised at the sight of the uncanny phenomenon. I recollect that I grabbed my cap and run up the stairs, knocking somebody down as I flew by, pushed the trap open and sank down on the roof almost exhausted. Mechanically I pulled out my watch. It was 11:59. I shivered and looked intently at the moon, sailing in a beautifully clear sky, in which the stars sparkled with unusual brilliancy.

The moon was half full, the dark half being jet black and undistinguishable from the black sky. A clock near by started to strike 1 o'clock. The sound was still vibrating in the air when I witnessed a most remarkable phenomenon. The dark portion of the moon was suddenly faintly illuminated with the same scarlet phosphorescence which I had seen but a few seconds before around my receivers.

It seemed to me as if there was a gigantic searchlight stationed on the bright side of the moon, throwing a colossal shaft of that scarlet light over on the dark side. This shaft of light was not stationary, but it swept rapidly back and forward over the dark face of the moon, illuminating the moon's craters in a wonderful fashion. The phosphorescent light shaft was so long that it went actually clear across the face of the moon and swept out into the space beyond for a considerable distance. It was the most magnificent, inspiring spectacle I had ever witnessed in my life. Suddenly the light vanished for a short period, just as the mysterious party had said it would. I counted to 10. Just as sudden the sweeping light shaft appeared anew brushing the moon's dark face a few times back and forward as before. The light disappeared again; I counted to 10 and it reappeared, going through the identical motions for the third and last time.

For a few seconds I stood fascinated probably with my mouth wide open. Like in a trance, I went down to the wireless, and I still remember while adjusting the 'phones over my head that my teeth were chattering violently and that I had a cold chill which shook me from head to foot.

I had scarcely adjusted the 'phones when the high pitched screaming sound was heard again, and in a few seconds the voice with the graveyard tone spoke once more:

"I trust, my boy, that you will not doubt again Baron Münchhausen's word," here I could distinguish a low chuckle, "but tell me, how did you like my little exhibition?" "Why, your excellency," I stammered back into the transmitter before me, "I really had no idea of offending you before, the whole thing seemed so impossible to me that you can hardly blame me for doubting your words. However, after seeing your wonderful lunar fireworks I stand ready to believe anything and everything that you may say. I assure you I will swear by it. But would you be so kind to answer me the burning question which is uppermost in my mind just now? Am I not correct in my assumption that your excellency was born in 1720 in Hanover, Germany, and was buried in 1797 in the same locality?"

"Most assuredly, my boy, you have stated the facts absolutely correct. As you say, I was buried in 1797, but if you were to open the coffin to-day you would not find a bone of Baron Münchhausen. For political reasons it was very desirable for me to 'die' in 1797, for if I had not 'died' just then they would have hung me dead, no doubt. So I had a wax replica made of myself, which looked so much like my dear self that it even deceived my trusted valet, Fritz, who came within an ace of placing me in the coffin while I was sleeping peacefully but soundly in a secret room in my attic alongside of my wax figure. If I had not sneezed in my sleep they would have buried me undoubtedly and let my wax replica shift for itself in an unfriendly world. While this might have been a regrettable accident, it would have hardly affected me much, for I am immortal, as you no doubt know!" A chuckle was discerned by me at this pun, the Baron no doubt liking his own little jokes.

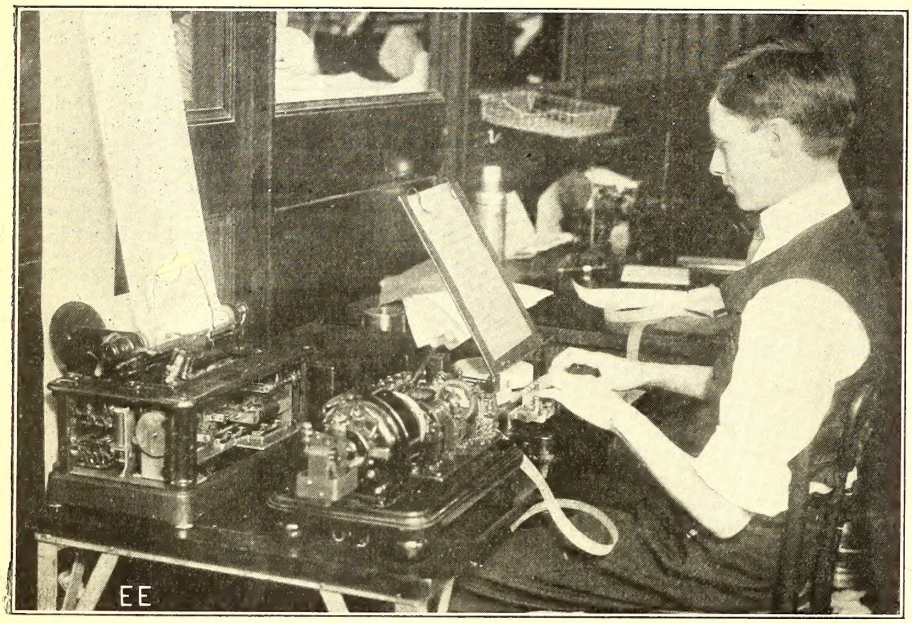
"However, in the absence of Fritz, that blunderer Rosskopf, the embalmer, enters the house very much under the influence of Schnapps and by pure chance finds the secret room. He sees me sleeping soundly and thinks, of course, that I am dead. He, being either too lazy or else too drunk, I never knew which, he fails entirely to cut me open and to embalm me in the usual

(*Continued on page* 10).

How We Get Our War News

A Glimpse Inside the "News" Lines. By H. Winfield Secor

THE problem of gathering and properly distributing to the various newspapers throughout the country, the latest war news, or in fact news of any character, is one of the greatest problems encountered by the Associated Press Bureau. This useful news organization has its main offices located in New York City, where it has facilities and the necessary electrical installations and circuits, enabling it to promptly receive and transcribe all the latest news from every part of the country and also from the cables across the ocean as well as long distance wireless.



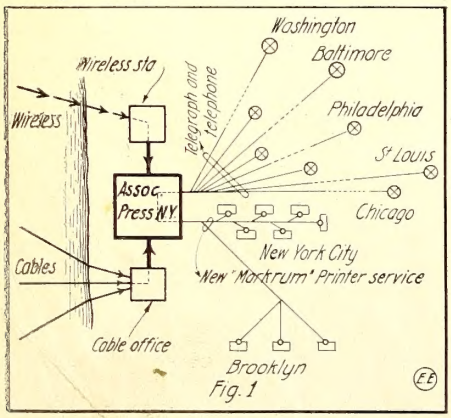


Photo (C) by Underwood & Underwood.
Showing Morkrum Sending and Receiving Printing Telegraph System Installed in Associated Press Offices in New York City. Local Printer to Left.

When the news is received in the forms of telegrams, etc.; after the news is edited, it is transmitted to the various newspapers throughout the country and city who subscribe to this press service. So far, and as has been the case for many years, the news is transmitted to outlying districts and distant cities by Morse code over the telegraph wire. However, a newly perfected transmitting system, known as the "Morkrum" arrangement, is now in use for New York City and vicinity by the Associated Press. It may be remarked to start with, that in the news transmitting office of this association, there are handled on the average 32,000 words per day.

The diagram at Fig. 1 will make clear how the network of "news" gathering and distributing lines terminate in a common clearing house, or as we know it, the Associated Press. Cables and radio bring in the news from across the ocean, while telephone and telegraph serve to handle the land "news" service.

How the Associated Press Gathers and Distributes "News" From New York City as a Center.

With the previous arrangement and making use of Morse telegraph operators for transmitting this news to the various newspapers in New York and Brooklyn, it required a great many extra messengers to deliver some of the news, and also a number of Morse operators; as the average speed available by this form of electrical transmission of intelligence is rather low or about 25 to 30 words per minute.

We show herewith the new Morkrum code (Fig. 2), as used with their machines, and as seen a series of round perforations in a paper tape serve to transmit the proper sequence of electrical signals over the line to the various newspapers, to actuate a printing receiver at the end of every line. Fig. 3 shows a specimen of this perforated paper tape. This tape is prepared very quickly and easily by means of a perforator in the form of an ordinary typewriter with a keyboard exactly similar, so that any typist may with very little instruction and practice operate same successfully. By reading the rows of dots across the paper in connection with the code here given, the reader can very easily decipher the meaning of the news item included on this particular piece of tape.

We show herewith also illustration of the transmitting and receiving instruments of the Morkrum pattern and two of the transmitting instruments are now in use in the Morkrum transmitting room of the Associated Press. These two instruments work simultaneously sending out news over a common circuit of two wires. Whatever papers require the news at the particular moment are switched on to the transmitting circuits by means of a plug and jack switchboard, similar to that used in telephone work. Means is provided for the attendant at each receiving station to notify the sender of trouble with the machine.

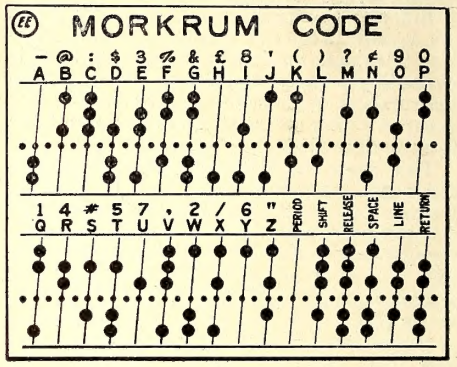

Fig. 2.
The New Morkrum Automatic Printing Telegraph Code.

The instruments are of the very finest workmanship, of course, and work with lightning rapidity and precision. The transmitter in the form of a typewriter as already mentioned, also includes the transmitting battery of polar relays; to the number of 12, which successively send out at high speed, the necessary positive and negative electrical impulses over the line to the receiving printers. As soon as the end of a printed line is reached a red light glows under the keyboard of the transmitter. The operator then presses his shift key for line spacing as many times as the printed lines are to be spaced apart. At each transmitting station, a local printer is simultaneously operated so that all of the messages sent out can be checked or watched to see that the spelling is correct and that one line is not being printed over another, etc.

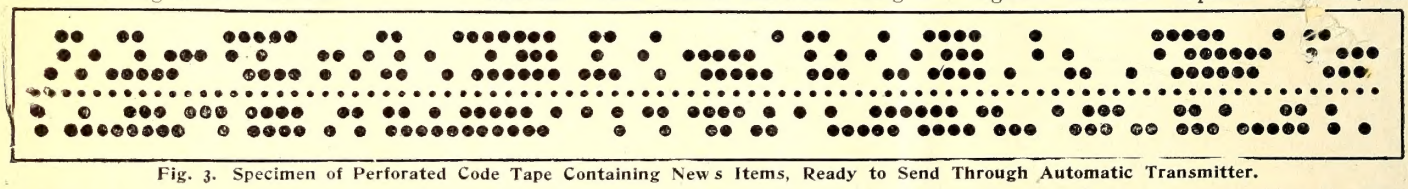

Fig. 3. Specimen of Perforated Code Tape Containing News Items, Ready to Send Through Automatic Transmitter.

As the speed of this system is much higher than that available when ordinary Morse telegraph instruments are utilized and when the greatest rush of news occurs; which is, by the way, about 11 a. m. to 1 p. m. each day; it is generally the case that three operators or more perforate the tapes simultaneously, as these tapes can be passed through the transmitting machines at very high speed, say 60 to 70 words per minute and more. It is thus seen that two transmitting keys using this tape, can take care of as many as four operators. The received news at each station is printed in type on a continuous paper roll about eight inches wide. It is detached from the printer as the machine feeds it out.

Electricity and Nature—A Thunderstorm Primer

(Concluded)

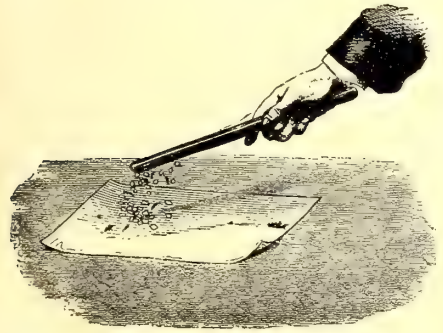
What is Voltaic electricity?

Voltaic electricity is the electricity that is developed during *chemical changes,* and is so called after Volta, who enlarged upon the theory of Galvani.

What are the differences between mechanical, or friction electricity, Voltaic electricity, Galvanism, and magnetism?

Frictional electricity is electricity *sud-*

The Aurora Borealis or "Northern Lights." Believed to Be of an Electrical Nature.



denly liberated under the effects of the *motion,* or the mechanical disturbance of bodies.

Voltaic electricity is a *steady flow* of an electric current, arising from the *gradual changes of chemical* action.

Galvanism and *Voltaic* are also *identical,* since the latter is founded upon, and is a development of, the former. But the term *Galvanism* is frequently used when speaking of the development of electricity in *animal bodies.*

Magnetism is the electricity of the *earth,* and is also understood to include the *fixed electricity of terrestrial bodies.*

Man knows not *what electricity is;* yet by an attentive observance of its *effects,* he avails himself of the power existing in an unknown source, and produces marvelous results. When the Grecian philosopher, Thales, sat rubbing a piece of amber, and watching the attraction of small articles of matter to its surface, he little knew of the mighty power that was then whispering to him its offer to serve mankind. And when Franklin, with the aid of a boy's plaything, drew down an electric current from the clouds, and caught a spark upon the knuckles of his hand,

Illustrating the First Principle of Electricity. The Electrified Stick of Sealing Wax.

even he little conjectured that the time was so near when that strange element, which sent its messenger to him along the string of a kite, would become one of man's most submissive servants.

So many great results have sprung from the careful observation of the simplest phenomena, that we should never pass over inattentively the most trifling thing that offers itself to our examination. Nature, in her revelations, never seeks to *startle* mankind. The formation of a rock, and the elaboration of a truth, are alike the work of ages. It was the simple blackening of silver by the sun's rays which led to the discovery of the *chemical agency of light.* It was the falling of an apple which pointed Newton to the discovery of the *laws of gravitation.* It was the force of steam, observed as it issued from beneath the lid of a kettle, that led to the invention of the *steam-machine.* And it is said of Jacquard, that he *invented the loom* which so materially aided the commerce of nations, while watching the motions of his *wife's fingers,* as she plied her knitting. As great discoveries spring from such small beginnings, who among us may not be the herald of some great truth—the founder of some world-wide benefaction?

That the area of discovery has not perceptibly narrowed its limits, is evident from the fact that the greatest elements in nature are still mysteries to man. And though it may not be within the power of a finite being to unravel the chain of wonders that enfold the works of an infinite God—still it is evident, from the progress which discovery has made, and from the good which discovery has done, that God *does* invite and encourage the human mind to contemplate the workings of Divine power, and to pursue its manifestations in every element, and in every direction.

The wonderful force of *electricity* astonishes us the more when we view it in contrast with that equally wonderful element, *light.* We have seen that light travels with a velocity of 186,000 miles in a second, but that it falls upon a delicate balance so gently, that it produces no perceptible effect. As far as we know the nature of *electricity,* it is even *more etheral* than *light;* yet, while the *ether of light* falls harmlessly and imperceptibly—even with the momentum of a flight of *ninety-five millions of miles,* the *ether of electricity,* bursting from a cloud only *five hundred yards* distant, will split massive stones, level tall towers with the dust, strike majestic trees to the ground, and instantly extinguish life of man! *Why* does *the one ether* come divested of all mechanical force, while that which seems to be *even more etheral* than it, is capable of exerting the mightiest force over material things? Does it not appear that the Creator of the universe has established these paradoxes of power to testify his Omnipotence—to show to man that with Him all things are possible; and that, in the grand cosmicism of the universe, every attribute of Omnipotence has been fulfilled?

Let us now consider man's relation to this Omnipotence. He sees that electricity smites the tall edifice, and observes that in doing so it displays choice for a certain substance through which it passes harmlessly, and that its violence is manifested only when its path is interrupted. Man, taking advantage of this preference of electricity for a particular conductor, stretches out an arm of that substance, and points it upwards to the clouds; electricity accepts the invitation, and passes harmlessly to the earth. But this is not all; man learns by observation that electricity resides in all matter; that it may be collected or dispersed; that it travels along a good conductor at the rate of a *fifth-of-a-million of miles in a second of time;* he constructs a battery, a kind of a scientific fortress in which he encamps the great warrior of nature; and then, laying down a conducting wire, he liberates the mighty force; but its flight must be on the path which man has defined, and its journey must cease at the terminus which he has decreed where by a simple contrivance of his ingenuity (the movements of a magnetic needle), the electric current is made to deliver whatever message of importance he desires to convey. Thus, the element which in an instant might deprive man of life, is subdued by him, and made the obedient messenger of his will!

TO AVOID DANGER.

Why is it necessary to avoid proximity to water and streams during lightning?

Because water being a good conductor, a person standing near it, being also a good conductor, might determine the discharge.

Why is the middle story of a house the safest part to be in during an electric storm?

Because lightning sometimes *passes upward from the earth;* hence it is a mistaken notion of safety to take refuge in a cellar. In instances where houses have been struck with electricity from the earth, the force of the shock has abated as the electricity ascended.

Why is the middle of a room the safest place?

Because it is removed from *conducting surfaces,* such as bright mirrors, bell-wires, walls, cornices, etc.

Why is it advisable to stand on a thick hearth-rug or on a hair mattress?

Because, being dry, and non-conducting bodies, they would *insulate the human*

Showing the Effect of the Union and Separation of the Charcoal Points.

body, and prevent the electricity from passing to it.

Why is it dangerous to approach the fire-place in an electric storm?

Because the heated air, smoke, vapour and soot act as conductors.

Why should a person riding in a carriage during a thunderstorm, sit upright?

Because electricity may pass through the sides or back of the carriage.

The rule should be observed to avoid all *elevated* objects, which, as well as being elevated, are of a *slow conducting* character. The advice has been frequently given to avoid the neighborhood of conducting bodies; but when those bodies offer *perfect conduction* they convey electricity to the ground. Thus, to stand by or be within a church or lofty building, *properly fitted with lightning conductors,* is far safer than to stand near a tree, or a lofty building, *without a lightning conductor,* because electricity always seeks *the best conductor,* and the human body being a better medium than either a tree or a house, electricity would fly to it, even though it may first have seized upon one of the other objects. It must not be supposed that churches and houses having lightning conductors are not touched by electricity because no shock is felt or witnessed; their lightning rods are continually facilitating the movements of electricity, and probably passing, harmlessly, currents which, if resisted, would shatter the edifices to pieces.

LESSON 20.
HOW TO MAKE THINGS
(Concluded.)

Tap numbers each correspond to certain decimal parts of an inch, and can be found in any tap or drill catalog. A few of

A

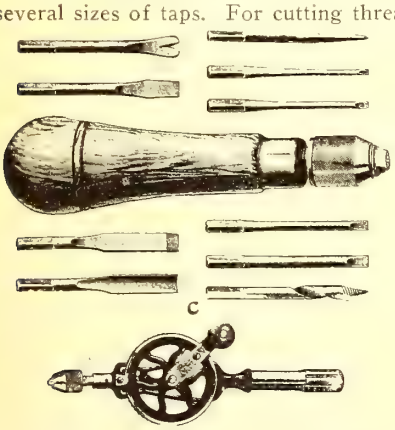
Fig. 4 B

Inside and Outside Calipers

Fig. 6
Small Drill Press

Fig. 5
Hack Saw

the common tap numbers and their inch equivalents are cited below (Kent):



Tap or screw number.	Diameter of body of screw. (Max. diameter.)
No. 2	.0842"
" 4	.1105"
" 6	.1368"
" 8	.1631"
" 10	.1894"
" 12	.2158"
" 14	.2421"
" 16	.2684"
" 18	.2947"
" 20	.3210"

As seen from the above, No. 14 size tap is slightly smaller than ¼ inch, hence it is nearly the same whether ¼"—20 pitch or No. 14—20 pitch is designated; but a ¼"—20 machine screw fits into a hole tapped with a No. 14—20 tap pretty snugly, and the exact designation should always be watched and adhered to.

Fig. 7 A

For tapping threads in holes a tap, Fig. 8 A, is utilized in a tap wrench or holder B. The holder has an adjustable chuck taking several sizes of taps. For cutting threads on rods, etc., a steel die and holder, Fig. 9, is employed. In drilling and tapping cast iron no oil is required. For working wrought iron or steel oil is always used. Brass, aluminum, or any other metals require oil for drilling and tapping of any considerable extent.

C

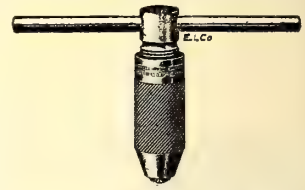


Fig. 7 B

A vise is essential in all shop work, and a neat one capable of being clamped to a table top is seen at Fig. 10.

A most useful machine is the lathe, upon which any shape of wood, fiber and brass may be turned up, and a good one for the amateur cost but little. A pair of heavy scissors, known as tinner's snips, are very handy for cutting out sections of thin fiber, tin, sheet iron, etc., not exceeding 1/16" thick.

For laboratory or shop use, in heating joints to be soldered, brazing and innumerable other operations, the Bunsen gas flame shown at Fig. 11 is a valuable asset. It uses the regular house gas, and by a set of air holes at the base transforms the flame into a strong blue one of intense heat, instead of the yellowish flame of low heat emitted by the usual tip.

For driving screws use is made of a plain or ratchet screw driver. A pressure exerted on the handle drives the screw or removes it, according to how the mechanism is set by the button on the side of it. This is a great time saver where many screws have to be placed.

B

Fig. 8 A

Wrenches of various kinds are used to handle rods, nuts and the like, a Stilson wrench for handling pipe, etc., being very useful—also for fitting round rods of any kind.

Muriatic acid cut by dropping bits of zinc in it may be employed as a flux to solder iron with, but for soldering electrical joints on copper wires it should never be used, only the non-acid fluxes such as rosin, being permissible.

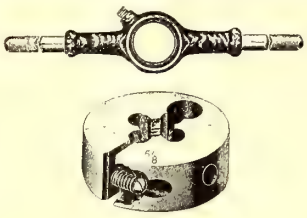

Fig. 9
Thread Cutting Die and Holder

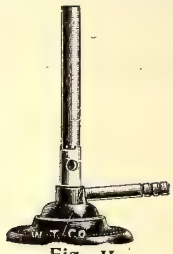

Fig. 11
The Bunsen Burner

Fig. 12 depicts a speed counter for taking the speed in revolutions of shafts, pulleys, etc. The speed of a belt driven shaft is dependent upon the proportion existing between the diameters of the driving and driven pulleys. Briefly expressed, it is as follows: The speed of one pulley, A, is equal to the product of the diameter of the other pulley in inches (say we call it B), by the revolutions per minute it makes, divided by the diameter of the pulley A, in inches, the result being in revolutions per minute (R. P. M.).

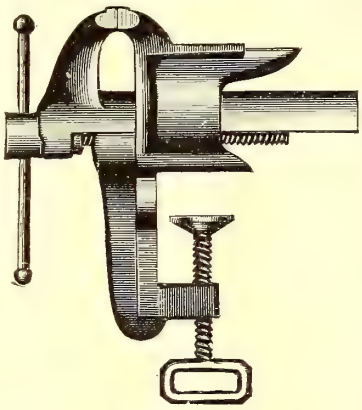

Fig. 10
Bench Vise

The speed ratio of gears is found by dividing the number of teeth on the large gear by the number of teeth on the smaller one. For example, suppose one gear had 100 teeth on it and the smaller one 12 teeth, then the ratio of speed would be 8 to 1, or the smaller gear wheel would make eight revolutions to every one of the larger gear. *(Finis.)*

PHOTOS OF MAGNETIC FIELDS.

An improvement on the method suggested by Mr. Hymes (February issue, page 148) for photographing magnetic fields is found in the use of blue-print paper in place of Velox.

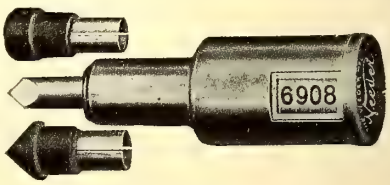

Fig. 12
Speed Counter

The blue-print paper is easy to manipulate, requiring only washing in water to fix the image, and is also not subject to fogging from premature exposure to ordinary sunlight. This makes its use more convenient.

When purchased in large pieces the paper can be obtained at 20 to 30 cents per yard, which is a very important item where a number of prints are to be made.

INDIANA RADIO AMATEURS: ATTENTION!

I am trying to get on foot a plan to unite the amateurs of the 8th and 9th Radio Districts within 100 miles of Angola, Indiana. I wish all amateurs who are interested would communicate with me. Yours truly, Leo B. Wilcox, 415 W. Park Ave., Angola, Ind.

Interesting Experiments in Electricity

By P. Mertz

No. 1. An Electric Pump

THIS pump is a purely electromagnetic one, and although it is extremely weak, nevertheless it is very interesting as a curiosity.

Referring to Fig. 1, A is a tin can; almost any size will do very well. In the bottom of the can is put a disc (B) of mica, celluloid, hard rubber or any insulator which is not affected by being immersed in water. C is as powerful a bar magnet as can be procured; it is better if it is of circular cross-section, as it will not interfere so much with the motion of the water.

A solution of copper sulphate in water is to be poured into the can. The terminals of a fairly powerful source of current (D) are then connected, one to the tin can (A) and the other to the bar magnet (C). As soon as the current is turned on the water will be observed to begin to turn around the bar magnet. If little pieces of paper, wood, etc., are dropped in the water the motion will be more easily seen. If the direction of the current in the water is reversed the latter will turn in the opposite direction. With a strong bar magnet and current the water will rotate at a pretty good speed. If the water rotates very slowly, or not at all, due to the current not being strong enough, this can be remedied by using a can of less diameter, so that there will be less water to move.

Although this apparatus is hardly worthy of its name as a pump, it is easily seen that the centrifugal action of the water as it rotates in the can suggests a somewhat more real pump.

The motion of the water can easily be explained from the diagram, Fig. 2. The current as it crosses from A to C encounters the magnetic lines of force of the magnet in such a way as to produce motion around the latter.

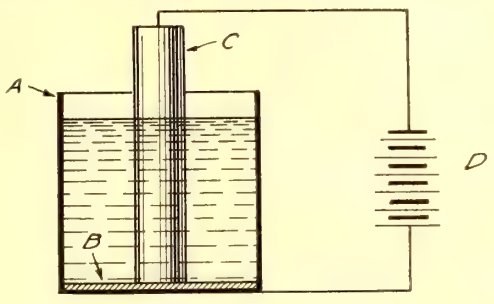

Fig. 1.

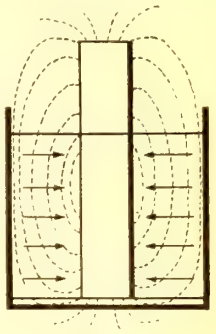

Fig. 2.

Diagrams Showing How a Copper Sulphate Solution Will Rotate Due to the Whirling Magnetic Field About a Conductor.

No. 2. A 500-Volt Dry Cell.

This dry cell, although having such an enormously high voltage, nevertheless occupies a space of only about 8x1½x1½ inches, and is as dry as the atmosphere which surrounds it.

It is made of a great number of thin paper washers about 1½ inches in diameter, painted on one side with aluminum paint and on the other with gold paint. As illustrated in Fig. 3, they are strung on a ¼-inch hard rubber rod, great care being taken to see that the aluminum sides of all the washers face one direction and the gold sides the other. The washers are compressed together between two metal washers, each under a nut screwed over the end of the hard rubber rod.

This forms a voltaic pile, the aluminum and copper faces, respectively, acting like the more usual zinc and copper discs, and the paper with the slight trace of moisture it gathers from the surrounding atmosphere, as the usual cloth wet with acidulated water. The extremely small amount of moisture is quite sufficient for generating the extraordinarily high (for a dry cell, at least) potential. The voltage of the cell can easily be tested if one end of it is grounded and the other touched to an electroscope. It will be noted, however, that the electroscope will take some time before deflecting, on account of the extremely minute current, which cannot charge it very rapidly. This current is so small that even a rather sensitive galvanometer cannot readily detect it, unless the diameter of the paper washers is quite large and they are quite moist.

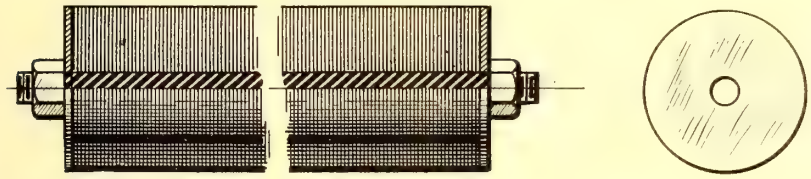

Fig. 3.

A 500 Volt "Dry Cell" Built on the Principle of the Voltaic Pile.

No. 3. The Electric Snake.

This is simply an iron tripod stand of the kind used in physics experiments (as shown in the illustration, Fig. 4), over which a solenoid has been slipped so as to make a magnet of it. At the top end a clamp is fastened to hold one end of a very flexible conducting cord, the other end of which is fastened to a screw, or whatever is handiest, on the top wooden end of the solenoid. The cord is connected in series with the solenoid with a fairly strong current, and a reversing switch is inserted in such a way as to be able to reverse the current in the cord without affecting that in the coil. By turning the switch first one way and then the other the cord will coil around the iron support in a way strongly suggesting a snake. The current, however, has to be fairly strong to make this experiment successful.

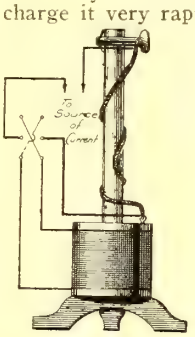

Fig. 4

Fig. 4 Shows an "Electric Snake" Experiment Easily Performed.

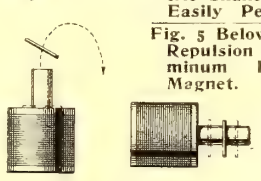

Fig. 5

Fig. 5 Below Depicts the Repulsion of an Aluminum Ring by a Magnet.

No. 4. Experiments with Induction in an Aluminum Ring.

If a light aluminum ring is slipped over one end of a fairly powerful electromagnet, such as is illustrated in Fig. 5, when the magnet is energized the ring will suddenly take a jump either toward or away from the coil. If then the current is reversed the ring will jump in the opposite direction. If the magnet is held vertically, instead of horizontally, the ring will be able to jump in only one direction (i. e., upward), but the length of jump will be increased, due to lack of friction. Indeed, if a strong enough magnet is used the ring will have no difficulty in jumping right off the magnet and landing on the floor. The experiment will be far more striking if the core of the magnet is made of a bundle of iron wires than if it is made of a solid piece.

If the magnet is energized with alternating current the ring will float in a certain position without apparent support. If disturbed from that position it will very gently and gracefully come back to it.

These experiments are especially mysterious to most because the ring is of aluminum, a non-magnetic material. The explanation, however, is simple; it is merely that a strong current (due to its low resistance) is induced in the ring, and this current generates a magnetic field, which, reacting with the field of the magnet, produces the motion.

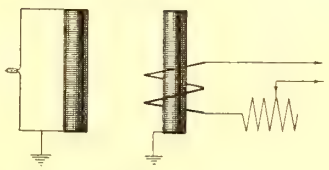

Fig. 6

In Fig. 6 Connections Are Given for a "Magic Light," Controlled by a Wave of the Hand.

No. 5. The Magic Light.

On the table are intricate apparatus resembling a wireless set and a Tesla coil. A few feet away is another Tesla coil, minus its heavy coil of wire, the fine coil alone remaining. The two ends of this coil are connected to a very small pea incandescent lamp, not lighted.

The performer turns on the switches; still the lamp does not light. He says a few occult words and waves his hands mysteriously around, and, lo and behold, it lights up! With a few more magic words and waves of his hands he extinguishes it. He then offers to blow it on. He first blows hard at it, but it does not light up; he comes nearer, blows very gently and, yielding to his coaxing, the

lamp lights up! He blows again and the light disappears from the lamp.

The electrical man in the audience is much peeved. "There are connections under the carpet," he says. The performer offers to try the experiment standing on a big board placed on the floor. He then does the same things, without the slightest lessening of his magic powers.

Various members of the audience offer more or less ridiculous explanations, but no one guesses the true one.

How did he do it? It is very simple. He had a Tesla coil rigged up with a tuning helix. The other Tesla coil was connected to the lamp, and one terminal of each coil was grounded. Just before the experiment the performer tuned the transmitter until the lamp brightened up, and then put in a trifle more inductance, just enough so that the lamp would be extinguished. Then he placed his hand near the receiver. The result of this was that the lamp circuit had more capacity than before, which raised its wave length and brought it in tune with the transmitter, lighting the lamp. When he waved his hands he brought them near the coil, and when he blew at the lamp he brought his head near the same coil. When he extinguished the lamp he merely moved away from the coil. No one ever guesses that the proximity of some part of his body to the coil has anything to do with lighting or extinguishing the lamp. When he got on the board he still had enough capacity to produce the desired effect.

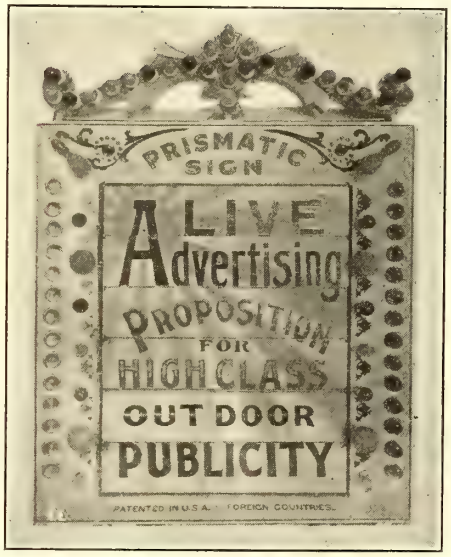
The whole thing is so simple that any wireless experimenter who has a transmitting set can easily repeat it.

A NEW ELECTRIC VAPORIZER.

For deodorizing, fumigating and medicinal purposes there has just been put on the market a new electric device of extremely simple construction known as the *Vaporel*. It consists of a blown-glass bulb about the size of a 25-watt tungsten lamp and similar in general appearance, as the illustration shows. It carries a standard screw base, so that it can be used in any lamp socket.

The glass bulb carries two spiral electrodes placed about 1 inch apart, and the current completes its path from one electrode to the other, through the oil solution poured into the bulb through an opening provided. When the oil is entirely vaporized the device shuts off the current automatically, or as soon as the liquid drops below the shorter electrode.

Ingenious Electric Vaporizer, which Fumigates Room in Few Minutes.



This simple vaporizing device has a wide field undoubtedly. It is recommended by physicians for inhaling or medicinal vapor treatment. Using the proper oil in it, the vapor will quickly kill the odor in kitchens, smoking rooms or any place where the air is befouled.

AN ELECTRIC MOTION SIGN.

By Frank C. Perkins.

The illustration shows a novel electric motion sign, operated mechanically and constructed of steel and iron, intended, when in register, to display a series of painted advertisements, they following each other at regular stated intervals, on a large, apparently unbroken display surface, which, in reality, consists of several separate and interchangeable parts. A unique feature obtained by this device is in that the exposed surface is made to disappear and is immediately replaced by a second surface, likewise composed of numerous units.

The change is effected very quickly and a series of four changes, following each other in regular rotation, are provided. These and other attractive results are attained by means of a series of prisms, each having four longitudinal faces and each carrying as many leaves, which are hinged to the edges of the prisms in such manner that when the prisms are at rest, all of the spaces between the prisms are closed by the leaves and the continuous surface presented alternately of prisms and leaves. The advertisement or advertisements cover the entire front surface and are, therefore, partly on the prism surfaces, and partly on the leaves.

Prismatic Electric Sign, Giving Very Spectacular Effects.

While the sign is in register for reading, there is a glare of white light brilliantly illuminating the advertisement. During act of changing from one advertising surface to another, while the white lights are off, various spectacular flash effects take place, each of the four changing periods varying in colored light effects.

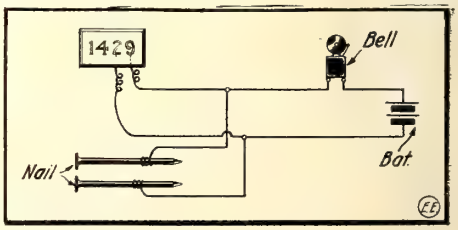
It is pointed out that the possibilities for beautiful illumination are unlimited with the mechanism of this device, and at a minimum cost. By means of lenses placed around the frame, a changing color scheme is presented with only a few lamps, having the appearance of many.

It is well known that *action* is an eye magnet. An ordinary sign 20 feet by 20 feet, contains 400 square feet of painting surface. The prismatic sign same dimensions, contains *four times* as much painting surface or 1600 square feet and occupies the *same* roof space.

The journals revolve on roller bearings, thus eliminating friction to a minimum, and in conjunction with a practical reduction gearing, it requires but a very small motor. It can be used as a two-way motion sign, showing advertising from opposite directions with same set of prisms and leaves, one side being painted on reverse side of leaves only, as leaves cover the reverse side of prisms. This gives 3,200 square feet of surface.

THE NICKEL-A-SHOCK MAN.

One of the many applications of electricity is that of giving shocks to the general public at 5 cents a shock. An outfit for the vending of such wares and its

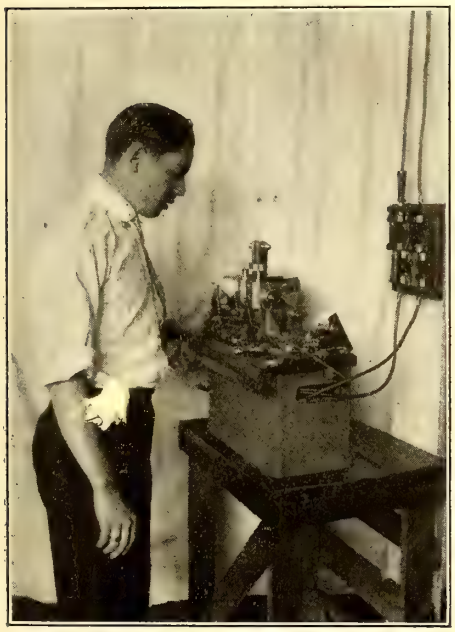


The Man Who Sells You Electricity at 5 Cents a Shock.

owner are seen in our illustration. This machine is familiar to those who live in New Orleans, and similar outfits are scattered throughout the country. A powerful-looking induction coil, appropriately trimmed up with polished brass balls and what-nots, serves to create a mysterious effect. A massive "current" gauge indicates how many "volts" are being taken through the handles shown.

SECRET CONTACT FOR CLUB BELLS.

When private clubs or houses desire a secret bell-ringing contact it is easily arranged for, as shown in our sketch. The two wires of the circuit are connected to any two metallic numbers on the house number, or the wires may be joined to two nails, et cetera. When the proper party comes along he simply short-circuits the nails or numbers connected to the bell circuit and the bell rings. Ordinary bell or annunciator wire No. 18 gauge is all right. A couple of dry cells and a 2½-inch gong bell complete the outfit. A knife or piece



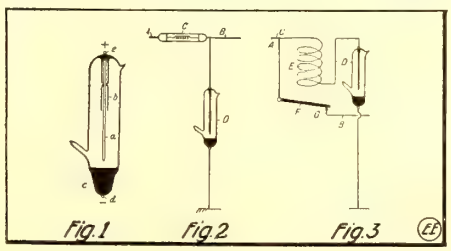
A Piece of Wire or Knife Blade Placed Across the Door Numbers, etc., Rings the Secret Club Bell.

of wire should be used to short the contact points on numbers.

RAPID ELECTRIC WELDING.

MACHINES of the butt welding type are now available for the manufacturer who has great quantities of one kind of work to weld electrically. They are not intended to replace the blacksmith where a variety of work is done, but on repeat work a boy with a welding machine can turn out more work than a dozen blacksmiths, and do it better, at a saving of anywhere from 60 to 90 per cent. in labor cost in many cases. Two pieces of metal are placed in the jaws of the welder, with their ends touching each other. The electric current is turned on and they instantly begin to heat. The boy operating the welder can see when the metal is white hot and begins to soften. He pulls a lever and forces the ends of the stock into each other. The metal is in full view of the operator at all times, instead of being concealed in the coal and flames of the "smithy's" forge. No smoked glasses or goggles are needed, any more than they are by the blacksmith. There is no scarfing to be done and, due to the way the metal is forced together, there is no oxidization, consequently no welding compound is required or used. The machine here shown is one of the Toledo Electric Welder Co.'s small machines.

This is not the case with fire welds, as the formation of scale due to oxidization, and the difficulty of applying the heat uniformly and welding quickly enough after taking from the forge, prevents the ideal conditions under which electric welds are made.



A Boy, with the Modern Electric Welder, Can Turn Out Remarkable Work in Quantity.

VACUUM TUBES FOR TELEPHONE AND TELEGRAPH LINE PROTECTION.

A very useful application of the vacuum tube was recently perfected to be utilized in telephone and telegraph line protection. Fritz Schroeter in the *Electrical World* describes a new form of vacuum tube which is effective down to 130 volts.

The construction is shown in Fig. 1. The anode (a) is an aluminum pin surrounded by a protective tube (b). The lower end of the anode (a) is at a distance of a few millimeters from the cathode (c) which is a fused alloy of potassium or sodium. Current is supplied through platinum wires (d) and (e). The tube is filled with a rare gas such as helium, neon, argon or a mixture of these gases at a pressure of from 1 mm. to 3 mm.

This tube may be used with connections of either Fig. 2 or Fig. 3. In Fig. 3 the telephone transmission line (A) is separated from the exchange line (B) by a relay consisting of three parts, E, F and G. When a dangerous voltage occurs a brush discharge takes place in the vacuum tube D because the high resistance of E (of about 8,000 ohms to 15,000 ohms) prevents the currents reaching an intensity sufficiently high for the evaporation of the cathode, which would produce an arc. The current passing through E excites the relay and attracts the armature F so that the contact between lines A and B is broken.

THE WOOLWORTH TOWER IN NEW YORK.

The tower of the Woolworth Building, a remarkable photo of which is shown here, is a veritable flaming torch at night, illuminated by the thousands and thousands of electric lights. The gilded surfaces of the mansard roof from the fifty-third to the fifty-eighth stories are turned at night into a glow of light which is even more picturesque than by light of day. Six hundred projectors, each containing a 250-watt Bryan-Marsh Mazda lamp of the new gas-filled type with closely contracted filament, in addition to the 24 1,000-watt lamps in the lanterns, help to illuminate the upper portion of the building, which houses over 30,000 inhabitants. The total power consumed is 175 kilowatts The installation required 50,000 feet of conduit from ½ to 3 inches diameter; 500,000 feet of No. 14 duplex wire were used. The reflecting characteristics of the glazed terra-cotta surface of the building and the necessity for mounting the large amount of equipment in a few restricted locations of the tower itself caused unusual difficulties in the design of the lighting scheme and equipment and in the installation features.

Beautiful Appearance of the Woolworth Tower, New York, Illuminated at Night. City Hall Park in Foreground. "Nickels and Dimes Built It."

LIBERTY BELL HEARD ACROSS CONTINENT.

The historic old Libery Bell, at Independence Hall, Philadelphia, which tried so valiantly to proclaim, far and wide, the joyful news of our declaration of independence, recently tried its voice again, and this time succeeded in making itself heard a thousand times further. Fitted under the bell was a telephone transmitter from the trans-continental line (it may be seen just below and in front of the bell), and when it was tapped with the mallet the ring of the cracked old bell was heard in San Francisco. A record of this historic event was made by a phonograph, seen in the picture, so that the tones of the veteran of Revolutionary times might ring down through the ages.

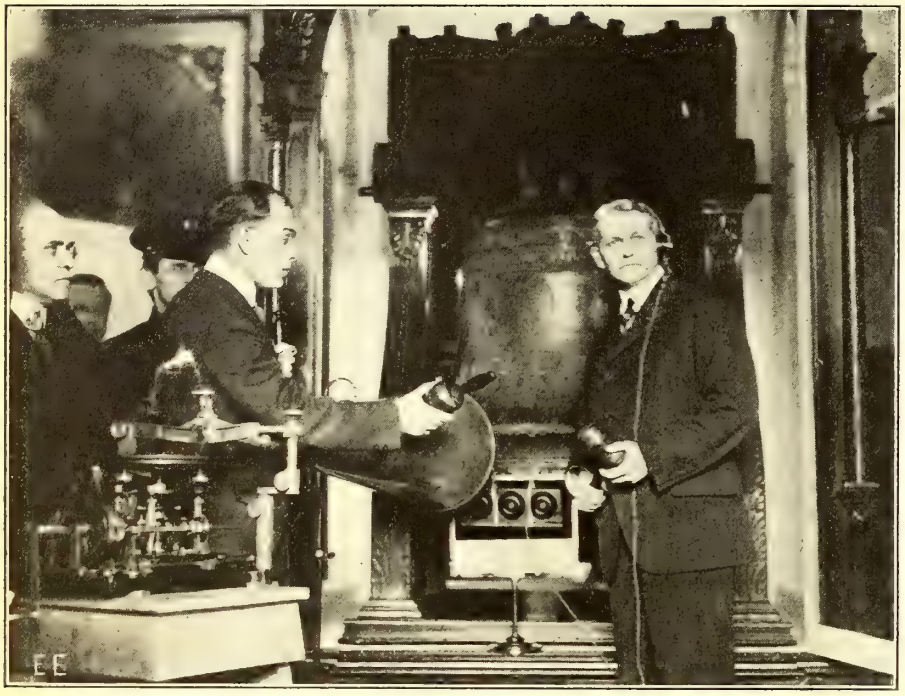

Photo (C) by Underwood & Underwood.

In the Recent Opening Tests of the Trans-Continental Telephone the Sound of the Liberty Bell Was Heard in Frisco. A Phonograph Also Recorded It.

ELECTRICITY IN NATURE.

(*Continued from page 5.*)

Why are lightning conductors attached to tall edifices, monuments, etc.?

Because they convey the electricity of the air and clouds *harmlessly* to the earth.

Why does copper form the best lightning conductors?

Because it has been found that electricity passes over a copper surface *more rapidly than over any other.*

Why do they convey electricity harmlessly to the earth?

Because electricity flies along their substance with great velocity; therefore it passes harmlessly away. It is only when its progress is *resisted* by a *non-conducting body* that electricity manifests *force.*

Do lightning conductors attract electricity?

They do not *attract electricity,* they merely afford it a *rapid conduction* when it happens to reach them. They no more attract electricity than water-pipes attached to a house attract water.

Why should a large building have several conductors?

Because elecricity may strike upon *any part* of a building. It is, therefore, proper to have several conductors, and to ramify their branches over the surface of the edifice, so as to form *a perfect system of conduction.* A ship having three masts, only one of which was protected, had her unprotected masts shattered, while the protected one remained untouched.

Why should the conductors terminate in earth?

Because then the electricity would be discharged from the conductors, and would have a *sufficient area of escape,* without creating a shock.

It is a good plan to attach the conductors to the gas-pipes in the earth, or to convey them to any body of water near the building.

BARON MÜNCHHAUSEN'S NEW SCIENTIFIC ADVENTURES.

(*Continued from page 3.*)

manner, luckily for me. Instead of which he uses a hollow needle and injects the embalming fluid into my veins. I am a sound sleeper. A very sound sleeper. Suffice it to say I did not wake up for a long time. As time goes, a rather very long time. To be accurate, I did not wake up for 110 years. It seems the embalming fluid that Rosskopf used on me was a good brand, for it did not wear out for 110 years, i. e., till A. D. 1907. It seems that this embalming fluid made my body rigid and stiff like stone, and to all intents and purposes, unknown to me, I was as dead as my wax replica, which they had buried the same afternoon. However, it seems my heart had continued to beat faintly through all these years and the prolonged rest, instead of aging my body, really made me younger. Although technically I am to-day almost 200 years old, I really feel like 30. You see what a good rest does! The next thing I knew was when I finally woke up and sneezed about 10 times. I was still on my bed in my secret room!

"You ask how it can be possible. Simplicity itself. Only Fritz and I knew of the secret room. Rosskopf, the embalmer, when he became sober again had promptly forgotten all about it, of course, so he really did not know any more than anyone else.

"As I found out afterward, this is what happened: Fritz, my trusted valet, had gone over to the burial vault to lock up the heavy oak door. But it seems that the door snapped shut while he was inside of the vault. As I lived alone with him, there was no one to release him but me, and he naturally thought I would miss him in time when I would, of course, release him. I did so—in time—110 years after! Poor fellow. I cried a bit when I saw his bones.

"But to go back. I said I woke up trying to sneeze my head off. For a few minutes I could not see anything for the dust I made while sneezing. I got up and felt rather stiff, and hungry as a bear. I opened the window and looked out. The strange sights I saw there fairly made me dizzy. It took me some hours to get used to it all; to make a long story short, it finally dawned on me that I must have slept for years. In the afternoon I cautiously walked down and inspected the house, which looked to me the same as on the day I went to sleep. I then ventured out in the neglected, unkempt garden, and after satisfying my hunger by means of a few dozen pears, I sat down on a decaying bench to think about the strange situation. While I was pondering about it I noticed a sheet of printed paper on the ground. It proved to be a part of a recent Hanoverian newspaper. I picked it up casually and tried to read the somewhat unfamiliar type. Suddenly I saw the date: September 29, 1907! It was then—for the first time in my life—that I fainted dead away; the shock was too great.

"But your time is limited, my dear boy, so I will make it short. Suffice it to say that after I came to I went over to the city hall and explained the whole affair to the Herr Bürgermeister—our mayor. I had no trouble of proving my identity, and the dear fellow overwhelmed me with kindness. He fêted and dined me and insisted that the town of Hanover should give a fitting celebration in my honor, but this, however, I declined modestly. In the course of the dinner he told me that, due to all good traditions of German official red tape, my house and estate were still in the process of liquidation, as I had neglected to leave a will. So I went and filed my will that very day and my lawyers assured me that, as I could prove my identity without doubt, I should be able to inherit my own estate within at least 25 years. They further assured me that I need have no misgivings as to my political offenses which I committed 110 years ago; they argued that these offenses had been outlawed. That took a big load off my mind. Well, I guess we've chatted long enough for to-day, besides my power is getting low. . . ."

"But, Your Excellency," I shouted back into my transmitter breathlessly, "won't you please explain how you come to be on such an outlandish place as the moon, and if you are there, how can you exist, for there is certainly no atmosphere on the moon and the temperature is below zero. . . ."

"I would gladly tell you all this now, but it takes time to explain these things," it came back very weak and distant, "but as I said before, my power is getting low, so if you will be at your 'phones to-morrow night at 11 p. m., terrestrial time, I will gladly satisfy your curiosity. Good night!"

(The next story is entitled: **How Münchhausen Took Berlin with the Allies.**)

A wireless station often contains enough fine wire to reach the distance it signals over. No "right of way" expense occurs though, or pole line cost either.

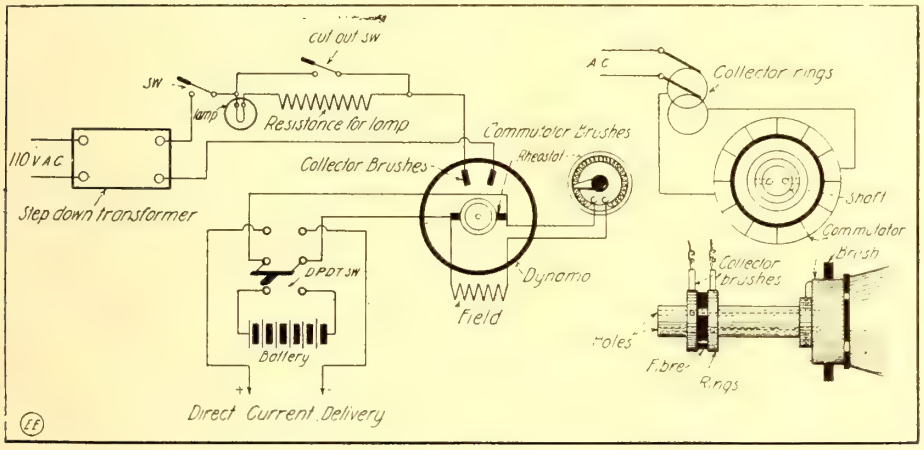
The mighty 42-centimeter siege guns of the Germans are fired by electricity, as also the large howitzers.

A Small Rotary Converter and Synchronous Motor

AS many electrical experimenters have great difficulty in obtaining at small cost a low voltage direct current supply to charge storage batteries, operate spark coils, motors and other apparatus, they will find the following very efficient:

The shunt-wound direct-current dynamo of the 8 volt, 10 ampere type, used in conjunction with step-down A. C. transformer, and an adjustable rheostat will be found very superior for this purpose.

The alternating current voltage should be a little lower than that of the dynamo at 3,600 revolutions per minute. Higher frequencies than 60 cycles cannot be used very well. Lower frequencies require less speed.



Two insulated collector rings of brass or copper are required on the shaft. A good place for these is between the commutator and the windings. They are connected to two opposite segments of the commutator (see drawing). Two brushes of springy copper or copper gauze, the holders of which are insulated from the frame with mica or fiber, are used in connection with the rings.

The dynamo should be brought to a speed of 3,600 revolutions per minute before connecting with the transformer. This may be done with dry batteries and varied with the rheostat in series with the field. When the desired speed is attained the switch which cuts in the synchronizing device may be thrown in. This device is a lamp of very low candlepower, equal to the voltage of both transformer and dynamo. If the candlepower is high the batteries may not be able to bring the motor to the desired speed, in which case a tungsten flashlight lamp with resistance in series is the best to use. Care must be taken to have sufficient resistance for the combined voltage of the transformer and dynamo to limit the current. The lamp should light up bright and go out, alternately, and while the light is out the switch which short circuits the synchronizing device (see drawing) may be thrown in and the batteries taken off. Direct current may then be taken from the commutator brushes.

If batteries are not available a hand drive may be used. In some cases the lamp may burn dim and continue so when the batteries are not strong enough to overcome synchronous speed. Then the short-circuit switch may be thrown in at any time and the batteries taken off.

This dynamo may be used to convert direct current to alternating current, the frequency varying with the speed, the direct-current supply being connected to the commutator brushes and the alternating current taken from the collector brushes and rings. This converter can also be used as an alternating current motor of unvariable speed, known as a synchronous motor, which is very desirable for driving rotary spark gaps in wireless stations, talking picture devices and many other purposes and applications.

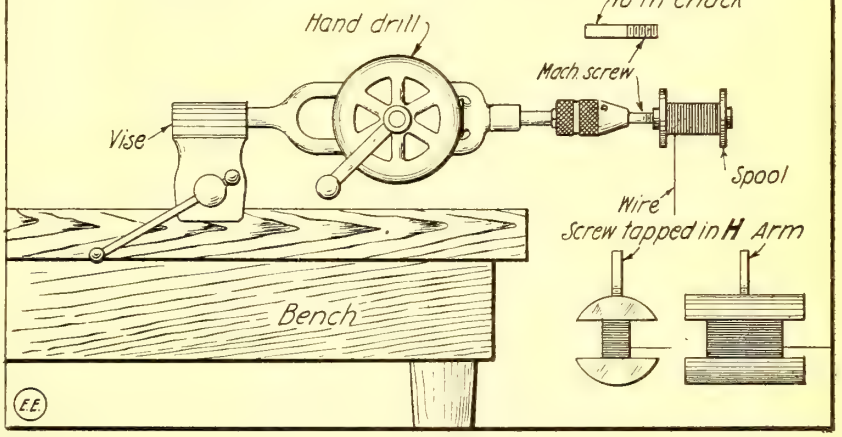
Simple Scheme for Making Any D. C. Dynamo a Synchronous A. C. Motor or Rotary Converter.

HAND-DRILL COIL WINDER.



I made a very simple and durable winding machine from a hand-drill.

I clamped the hand-drill in the vise by the projection of the bearing of the large gear at the back of the drill; then clipping the head off of a machine screw that would fit the magnet I wished to wind. I then fastened it in the chuck, screwing the magnet core on this and proceeded to wind on the wire by turning the handle.

Afterward I wound the bell coils of a telephone and the "H" armature of a telephone generator in the same way. On the armature I had to thread one of the holes with a tap wrench and tap.

Showing How to Wind Magnet Coils, Shuttle Armatures, etc., with Ordinary Hand Drill in Vise.

TUNING COIL SLIDERS.

I have had great trouble with sliders for tuning coils. I have had success with the style I am going to describe. The greatest trouble is making the contact strip and fastening a handle. To make one proceed as follows:

Simple Rheostat or Tuning Coil Slider Made from Piece of Square Brass Tube.

Get a piece of square brass tubing about 3 inches long and large enough to slip over the rod easily With a hack saw slit it down 1½ inches (at A); then bend back and cut the remaining part out. Now drill a 11-64-inch hole (at B). Next, with a center punch, make a small dent (at C). An ⅛-inch 8-32 screw passes through the upper limb as a fastening for the handle.

Submitted by EDWARD MINNIS.

RADIO-CRYSTAL SENSITIVITY.

B. Hoyle referred to experiments carried out in order to ascertain the effect of frequency on crystal sensitiveness in a recent talk at Liverpool, Eng. Carborundum, which was known as a definite rectifier of oscillations, and perikon and radiocite, which were thermal in action, had been investigated and found to be very constant over a range of frequencies varying from 100,000 to 1,500,000 per second. Regarding the thermal action on low oscillating currents changing to valve action for large currents, experiments carried out by the speaker had shown that up to 12 or 14 microamperes the ratio of current in one direction to current in the other was unity, but above this value the ratio gradually increased to three or four to one.

The telegraphone records telephone speech by magnetizing a moving iron wire.

WRINKLES—RECIPES—FORMULAS

Edited by S. GERNSBACK

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA No. 9.
Cements for Work Shop.

Leather Belting Cement.—Take 1 part of *Common Glue;* 1 part of *American Isinglass.* Place them in a boiler and add water sufficient to just cover the whole. Let it soak 10 hours, then bring to a boiling heat and add pure *Tannin* until the whole becomes ropy or appears like the white of egg. Apply it warm. Buff the grain off the leather where it is to be cemented, rub the joint surfaces together; let it dry for a few hours, and it is ready for use. It will not need riveting, as the cement is nearly of the same nature as the leather itself.

Cementing Brass to Glass.—16 parts of *Copal Varnish;* 5 parts *Drying Oil;* 3 parts *Turpentine;* 3 parts *Oil of Turpentine;* 5 parts *Liquid Glue;* 10 parts *Stucco.*

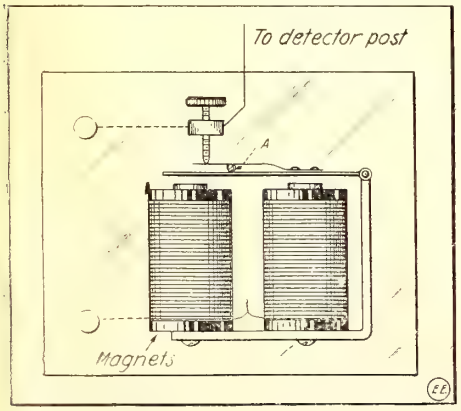
Cement for Glass and Porcelain.—1 part of *Casein;* 6 parts of *Sodium Silicate.* Dissolve; apply at once and dry in the air.

Chemical Cement.—Mix together 5 lb. of *Resin;* 1 lb. of *Wax;* 1 lb. of *Red Ocher;* 2 oz. of *Plaster of Paris.* Melt the whole with moderate heat.

Cutler's Cement.—4 parts of *Resin;* 1 part of *Beeswax;* 1 part of *Plaster of Paris.*

Electrical Cement.—5 oz. of *Resin;* 1 oz. of *Beeswax;* 1 oz. of *Red Ocher.* Dry the ocher on a stove. Melt the wax and resin together and stir in the powder till cold. Best cement to fasten brass on glass tubes, etc.

Iron Cement.—7 lb. of *Iron Borings;* 2 oz. of *Sal Ammoniac;* 1 oz. of *Sulphur; Water* in sufficient quantity.



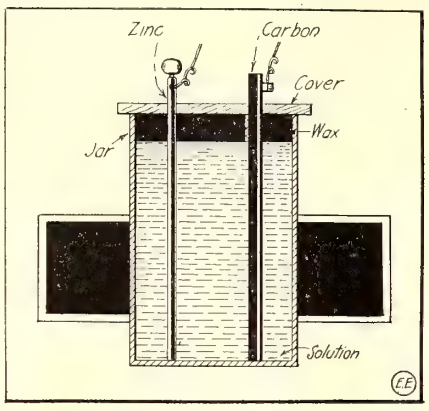
Stone Cement.—25 parts of *Linseed Oil;* boil with 35 parts of *Litharge* and 250 parts of fine powdered *Burned Lime.* Use hot.

Waterproof Cement.—1 part of *Glue;* 1 part *Black Rosin;* ¼ part *Red Ocher.* Mixed with least possible quantity of *Water.*

Cement for Wood.—Melt in an iron pan 1 oz. of *Resin;* 1 oz. of pure *Yellow Wax,* and stir in 1 oz. of *Venetian Red.* Use while hot. When cold it is as hard as stone. S. G.

MAKING THE BUZZER HY-TONED.

Some amateurs may be troubled by the harsh tone of the buzzer test. I remedied



A Piece of Match "A" Between Armature and Spring Gives Hy-note.

this trouble in a simple manner, and the buzzer now sounds as good as the navy type. Secure a piece of match stick (a) about ⅜-inch long and pry it between the little piece of metal that is fastened on to the vibrator proper and the vibrator. It will be found that the note of the buzzer is increased in this way considerably.

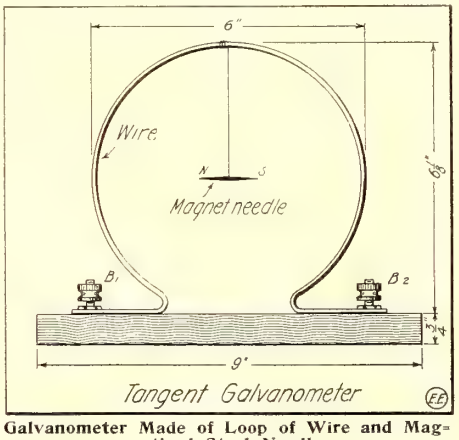
A SIMPLE BICHROMATE CELL.

A very simple bichromate cell can be made as follows: Place an ordinary car-



A Powerful Battery for Experimental Work.

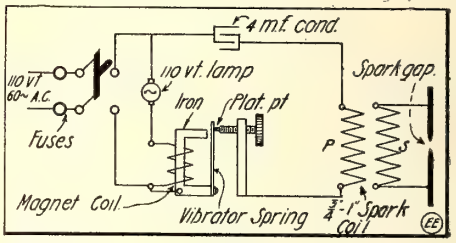
bon rod and a circular zinc rod into a jar, as shown in illustration. The electrolyte consists of a mixture of one part of potassium bichromate to two parts of concentrated sulphuric acid, and the rest water. The cover and top of jar should be well coated with paraffin. Care should be taken to remove the zinc rod from the solution when the cell is not working. This cell is excellent for running motors and spark coils.

HOW TO MAKE A TANGENT GALVANOMETER.

Procure a wood base 3x6x¾ inch and on it drill two holes for the binding posts B1 and B2. Then take a piece of copper

Galvanometer Made of Loop of Wire and Magnetized Steel Needle.

wire or rod about ⅛ inch in diameter and nearly 22 inches long and bend it so as to make a circle 6 inches in diameter. Before doing this it is better to hammer the ends down flat, but do not drill the holes for the binding posts until you know where they come to. Next set this up on the base with the binding screws, which act both for connection of the electric current and support.



Next magnetize a steel sewing needle and tie a piece of fine thread (preferably a fine strand of silk) to the center of it and tie the other end on the top of the circle so as to let the needle hang in the center.

The coil can be made of several turns of No. 18 D. C. C. bell wire, etc., and the magnetic effect on the needle will then be greatly multiplied.

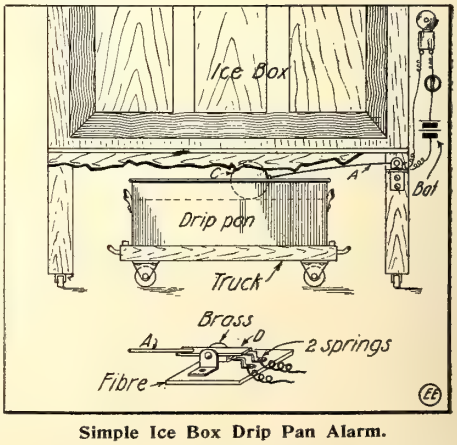
UNIQUE A. C. OPERATION OF SPARK COILS.

A very novel arrangement for operating ¾ to 1-inch spark coils directly from 110-volt 60-cycle A. C. circuit which has been used considerably in practise is shown in the accompanying diagram. As will be seen, a vibrator is utilized, which has a laminated sheet-iron frame, U shaped with a thin piece of clock spring as an armature, secured to the longer leg of same. A coil of wire is wound on the central leg of the iron core, and the alternating current, passing through this coil and a 110-volt lamp, sets up a rapidly fluctuating or alternating magnetic force in the iron. This force, acting on the vibrator spring, manages to interrupt the contacts regularly, the same as any other vibrator used on spark coils. One of the most novel features of this arrangement lies in the fact that the spark coil primary P is connected in series with a 4 M. F. tinfoil and waxed paper condenser, such as used in telephone work, as indicated. The coil thus derives just sufficient

Efficient Way to Operate Spark Coil on A. C.



current through this condenser, which is of considerable capacity, viz., 4 M. F.

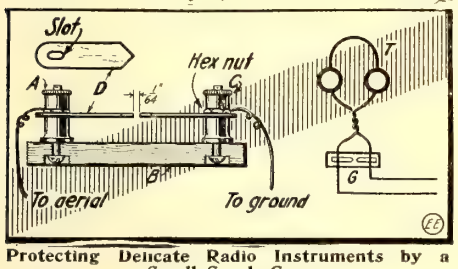
A DRIP PAN ALARM FOR ICE CHESTS.

I wish to make a contribution to your magazine in the form of a "Drip Pan Alarm," which I believe will be in demand in nearly every home.

Its construction is very simple and the illustration makes it all very plain. All that is needed is an electric bell, wire, batteries, an empty condensed milk can and a slender stick or brass rod about ⅛ inch diameter. The bell is fastened on the side of the ice box and connected with the batteries as shown.

The milk can C is sealed up to act as a float at the end of rod A. The other end of A is threaded in a swivel piece D. This in moving downward makes contact across the two brass springs shown, which are mounted on the fibre base plate. Two brass "L" pieces serve as trunnions for the shaft pin of D-A.

Simple Ice Box Drip Pan Alarm.



As the drip pan gets full of water the float C rises and eventually closes the bell circuit through the springs.

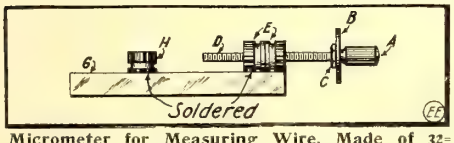
RADIO RECEIVER PROTECTIVE GAP.

A very simple method of protecting wireless receiving sets and also the expensive and delicate telephone receivers is indicated by the small spark gap shown in the sketch.

This gap is made up simply from a couple of pieces of ⅛x⅜-inch sheet brass, etc., having the two abutting ends pointed. A couple of binding posts of telegraph pattern are mounted on a base B to support the two spark gap electrodes D. The gap is made very short when same is set, or about 1-64 to 1-100 inch. It is common in a great many stations, including commercial and other stations, to connect one of these gaps across the aerial and ground leads where they join the instruments

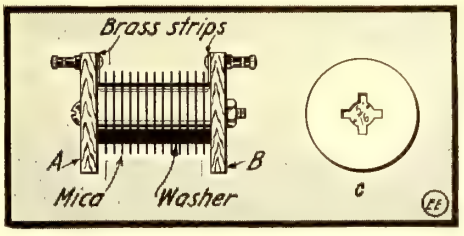


Protecting Delicate Radio Instruments by a Small Spark Gap.

proper, and also it is very advisable to place one of these gaps across the telephone receiver cord terminals as shown in the diagram, T being the telephones and G the protective gap. Any heavy static discharges coming down the aerial will thus jump these gaps and proceed to earth without affecting the instruments at all. Such static discharges will take the shortest path via the gap in preference to the high impedance circuit through the 'phone windings.

A CHEAP MICROMETER.

The drawing shows how to construct a micrometer which gives fairly accurate results, and it is handy to measure thickness of glass for condensers, etc. At G is a piece of ¼-inch-square brass rod. At E are two brass thumb nuts from an old, dry cell, soldered to G. C is a hexagon nut, tapped 8-32. H is a brass thumb nut from dry battery and soldered to G, called the anvil. The screw D is taken from a dry cell and should have 32 threads to the inch. B is a washer and should have four notches filed in the edge. By unscrewing the screw one full turn from the anvil H you get 1-32 inch; one-half turn, 1-64 inch, or two full turns, 1-16 inch, etc. A is an electrose knob.



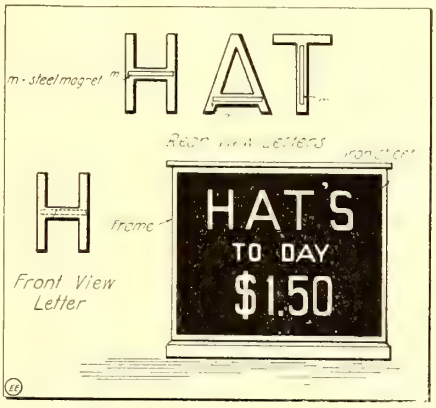
Contributed by DONALD HARDING.

Micrometer for Measuring Wire, Made of 32-Pitch Screw and Nuts.

A QUENCHED GAP FOR SPARK COILS.

The following is a description of a quenched gap which I have used successfully on my 1½-inch coil. The main idea may be obtained from the sketch. The end pieces, A and B, are of ¼-inch fiber, 1½ inches square. A 3/16-inch hole is bored through the center of each and another on corresponding corners. A 1½-inch bolt passes through the center holes and is taped on the inside to such a diameter that a washer having a 5/16-inch bore will fit closely on it. The length of the thread will depend on the number of plates used in the gap. Six or eight pieces of mica are then cut to the shape shown at C. Binding posts are placed in the corner holes and connected to the end plates with brass or copper strip. The mica rings and washers are then placed alternately upon

Simply Made Quenched Spark Gap.



the mica or oiled linen tape and the whole fastened together securely by means of the center bolt. The spark obtained with such a gap, although not of high frequency, is musical and produces a pleasant note in the phones.

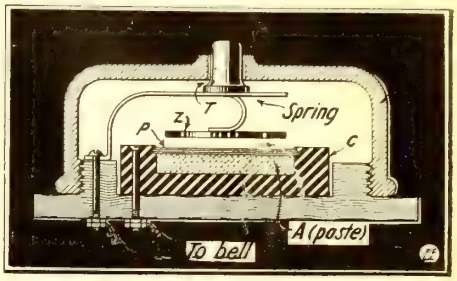
MAGNETIC LETTERS FOR WINDOW PLACARDS.

For rapidly and efficiently making up show-window signs or placards the latest conceit is magnetic letters, as shown in this illustration.

Expert window trimmers say that no show window is complete without a placard. But in windows in which the displays are changed often the expense for painting window placards is generally a considerable item in the advertising account. In fact, some electric companies pay from $3 to $7 a week for the painting

Window Placard Letters with Magnets on Them Enable One to Quickly Make Any Sign Desired.



of cards with catchy phrases, which they claim supply a finishing touch to their displays. The letters used with these magnetic signs consist of metal patterns faced with heavy baked white enamel. To the back of each letter is attached a small permanent steel bar magnet about ¾ inch long. The backgrounds for these letters are made of iron of such thickness that it can be handled easily and can, to enhance its appearance, be placed in picture frames of narrow but neat design. When a placard for a window is wanted it can be made at a moment's notice with this outfit by placing the letters in any desired position against the black iron background, the small bar magnet holding the letters in place. With this system the placard wording can be changed as often as is desired without additional expense. Any form of wording layouts is thus available to the window decorator. No current is used by the device, so the only expense is the initial cost.

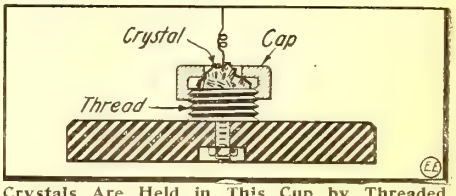
Electricity now pulls the boats through the Panama Canal.

MAKING A PUSH BUTTON BATTERY.

What would you think if you saw an ordinary-looking push button connected to a bell with two wires, no battery in the circuit, and upon the button being pressed the bell operated vigorously? The answer lies in the combined push and battery button illustrated in the diagram. Instead of two simple brass springs in the button cover there is a circular carbon block C, together with some blotting paper P and a small circular piece of zinc sheet Z. The button T presses down Z against the treated paper P, paste A and carbon C, thus forming a battery.

The blotting paper is first treated or saturated with a solution made of equal parts

A Push Button that Rings a Bell without Any External Battery.



of chloride of zinc and cooking salt. The paper is cut slightly bigger than the opening in the carbon block, so as to be held in place properly. In the circular recess under the blotting paper is placed a stiff paste made up as follows:

Two parts pulverized asbestos; 10 parts mercuric ammonium chloride; 3 parts cooking salt and ¼ part of chloride silver. Melt all parts together, and after they have cooled sufficiently they are pulverized. Then mix up a stiff paste by adding slowly chloride zinc and water. Fill the carbon recess A full of this paste. The zinc plate Z should be about 1¼ inches or larger in diameter, and the carbon in proportion.

This battery push button is capable of giving 1.6 volts, and will last four or five weeks or more on one charge of prepared blotting paper. This considers that the casing fits tightly to keep the battery chamber practically air-tight. Such a device is useful in many ways besides its "magic" effect on the uninitiated, who will hardly suspect that such a small device contains a battery.

A SOLDERLESS DETECTOR CUP.

This detector cup has been designed for the purpose of eliminating the use of a low temperature alloy and to enable a

Crystals Are Held in This Cup by Threaded Compression Cap.

quick change of crystals without changing the cup. There are two parts—the base on which the crystal stands and the shell which covers the crystal. The base is a circular piece of metal one inch in diameter and threaded on the side all the way around. There is a threaded shank on the bottom by which the cup is held to the detector base. The second part of the cup is a brass shell or cap to fit over the base and screw down on the mineral. It is threaded on the inside to fit the threads on the base. There are corrugations around the side of the shell or knurl to give a better grip.

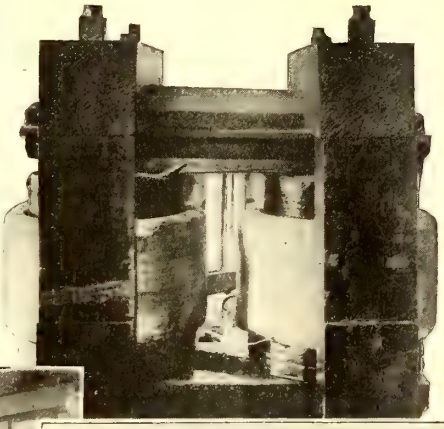
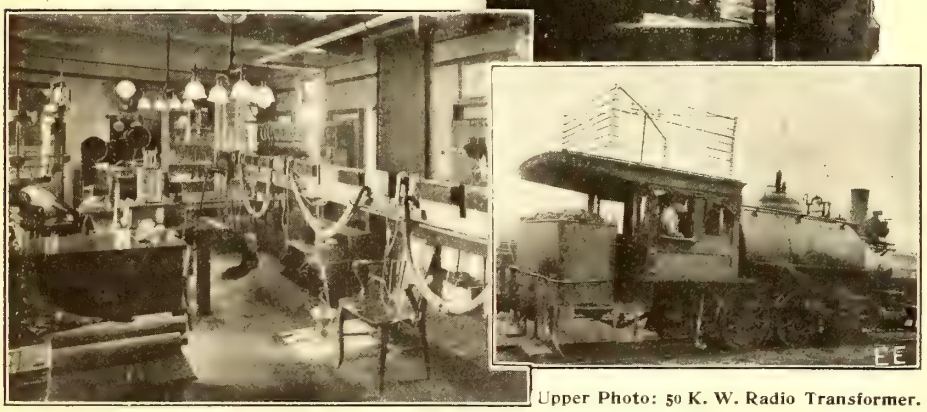
WIRELESS DEPARTMENT

Wireless Telephony and Telegraphy on Union Pacific Railroad

By Frank C. Perkins



THE accompanying illustrations show the electrical laboratory and railway equipment for work on wireless telegraphy and telephone service, which has taken place on the Union Pacific at its shops and headquarters, through the efforts of Dr. F. H. Millener, the wireless experimental engineer of that railway system.



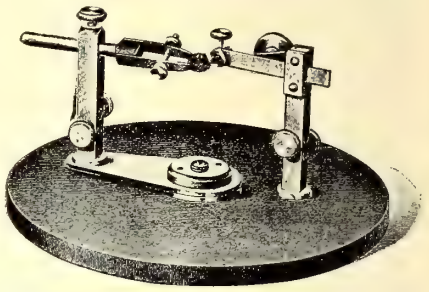
Dr. Millener has made some interesting experiments on the Union Pacific Railroad in the line of communication between trains, and between stations and trains, by wireless telegraph, wireless telephone, and by wire. He points out that "the commodity most in demand in the world to-day, and that which the world will pay the highest for, is speed. The second is safety, as safety lowers the price to be paid for speed, and any instrument or thing which will add to these two great commodities must have a value to mankind." The elevation at Omaha is 1,200 feet, gradually rising until an elevation of 8,000 feet is reached at the summit of Sherman Hill, Wyoming. In planning for wireless telegraph stations this elevation has to be taken into considertion.

It is pointed out by Dr. Millener that another thing which enters very closely into the consideration of the subject is static electricity. In summer the static electricity between Green River, and Cheyenne, Wyo., and Sherman Hill, Wyo., causes all sorts of disturbances with block signals, burning them out, and occasionally putting the wire telegraph out of commission. Therefore, as a result of experiment, it was decided that the induction coil method of generating wireless impulses, or waves of the 60-cycle, alternating current variety, would not be satisfactory; for, even if nine messages out of ten were received properly and the tenth not so, fate would in all probability make that message the most important one.

It is stated that various schemes were tried, but it was found that the best results could only be secured by using a higher frequency than 60 cycles. Therefore, for the stations at North Platte, Neb., and Green River and Cheyenne, Wyo., it was planned to use a frequency of about 550 cycles transformed up to about 12,000 volts in an open core transformer, with a 5 kw. generator at Cheyenne, a 5 kw. at North Platte, and a 10 kw. at Green River.

The station at Cheyenne is to work at all times, day or night, at least as far East as Omaha, and we hope an equal distance the other side of the mountains. The four stations—Omaha, North Platte, Cheyenne, and Green River—will thus work together at all times, and in all conditions of weather. In the telephone receiving the message from a high cycle, high frequency station, it is a high pitched note, similar in character to the sound of a tuning fork at 1,020 vibrations per second and is much pleasanter to listen to than the old 60-cycle low note. The sound also being high in pitch is not confused with static electricity; thus one of the greatest difficulties of the earlier wireless investigators is done away with.

Upper Photo: 50 K. W. Radio Transformer.



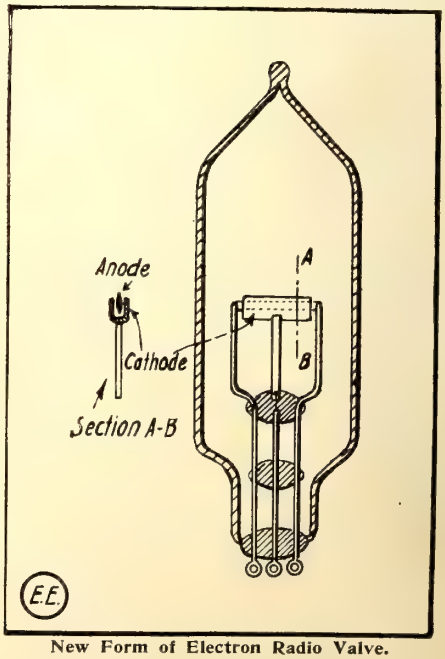
Left-hand Photo Shows Union Pacific R. R. Wireless Laboratory. To the Right Dr. Millener's Aerial Scheme for Locomotives.

As to aerials, or antennæ, it is said that in railroad work it is absolutely necessary to have the antennæ close and compact. In the first installation of the wireless telegraph station it is important not to complicate matters and to make the antennæ simple and easy to repair.

It is urged by Dr. Millener that the present tendency is toward using complicated apparatus and that this is not necessary; the simpler the better. It had been found that the use of the flat-top ships' antennæ is more practical than the umbrella type at stations, and parallel to the track, elevated by two self-sustaining towers, the height of which should be at least 210 feet and should be constructed to stand a wind stress of 90 miles per hour, at least, as we are building the wireless to work, when the wires go down.

A NOVEL DETECTOR STAND.

In the illustration here given is shown a novel radio detector stand, suitable for most any crystals, such as carborundum, galena, and silicon. It has a rotative arm,



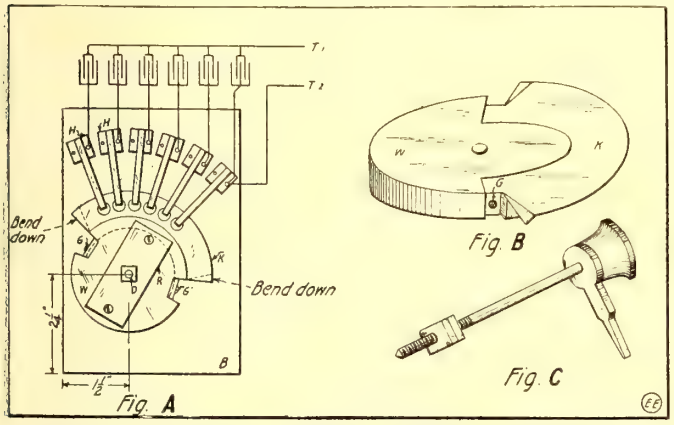
Carborundum Detector with Clamp Mounted on Rotatable Arm.

pivoted at the center of the base, which arm carries at its outer extremity an upright. This supports a sliding rod, having at its end a "drawing pen" type of crystal clamp.

A graphite or metal point is fitted adjustably on the other upright arm. Hence, most any adjustment desired can be obtained with this simple, yet ingenious, device.

A NEW WIRELESS VALVE.

The action of the kathodic detector or valve is based upon the peculiarity of hot, glowing bodies to send out negative emissions, which make it possible to ionize the space between the two electrodes of the detector. This makes it possible to use the valve as a wireless detector, for the reason that the received alternating currents and other very weak electromotive forces will be changed into uni-directional currents. The more powerful the emissions are, the more sensitive such a valve will be. The new Holweck valve recently invented has a kathode or a single metal piece whose sur-



New Form of Electron Radio Valve.

face is ten times as great as those that have been used heretofore in the audion type valve. Furthermore, this surface is covered with a certain oxide which has been found as being quite necessary for the action. The distance between the anode and kathode is reduced to 0.1 millimeter; on account of this very small distance between the anode and kathode, one obtains a very strong and sure action. It is, furthermore, not necessary to take any of the ordinary cautionary measures during the operation of the valve. The temperature of the kathode must be capable of being regulated, and the anode is placed in series with an electromotive force the same as in other valves.

This new valve has been used with great success at the Paris Eiffel Tower and at the Arlington station.

VARIABLE CONDENSER SWITCH.

It is invariably the lack of adjustable condenser capacity that causes the harmful sputtering and sticking at the vibrator contacts of spark coils, run on a fairly heavy current. Furthermore, the stumbling block in making a variable condenser is the switch. The following is a description of an efficient variable switch that is easily made.

Condenser Switch, Acting by Moving a Metal Disc Successively Under Metal Strips.

The materials needed are usually lying about any experimenter's workshop. Procure a piece of sheet-copper or brass about 6x3 inches; half dozen brass-headed tacks; an old watch spring, about ⅛" wide; a piece of ⅜" board, 4x6 inch; an oblong piece of 1/16" brass, 1x2¼"; and an ordinary spool from magnet wire.

Fig. "A" shows the bottom view of the switch, with condenser connections for six variations. Figs. "B" and "C" show the three parts of the switch detached.

"B" is the base, showing the six-clamp contacts at H—H. To make this part, take the piece of ⅜" board, 6x4 inches, and drill in it a 3/16" hole for "D", Fig. "A" 1½" from one side and 2¼" from one end. From center of "O", with radius 3¼", describe an arc. This will form the outer boundary of the springs at H—H.

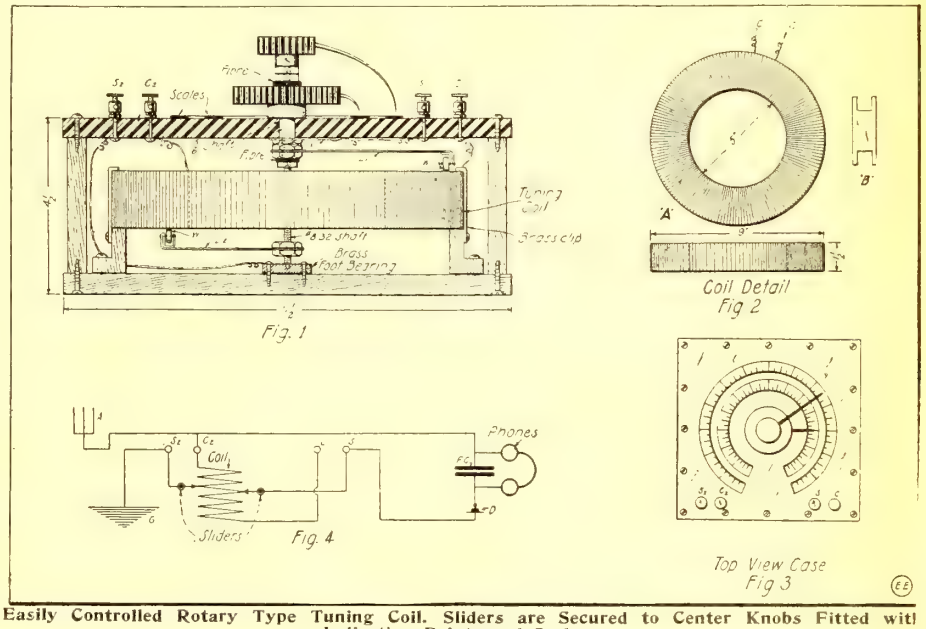
To make the clamp contacts, first break off six 1¾" pieces from the watch-spring. Cut 6½" squares from the copper plate, and, with large shears, clip off the heads of six brass-headed tacks. On one end of each piece of spring solder one of the copper squares; on the other end, a brass tackhead. Of course, the soldering is done on the concave side of the head. A good plan is to clamp the springs down, tack heads and copper squares in position, and to drop solder on each end. When the soldering is finished, plunge the springs into cold water to retain the temper of the steel. Screw these clamp contacts down as shown.

Fig. "A" shows the upper side. To get the wooden wheel for this part, saw off one end, "W", of the spool. Nearly opposite each other (about 160 degrees apart), cut two grooves, G and G', on this wheel. From the sheet copper, cut a circular blade, "K," ⅞" wide and 160 degrees long. The radius for the outside circle for this is 1⅞"; of the inside, 1". Cut a slit ½" deep, ½" from each end of the blade; bend the copper around and screw to the wheel as shown at G and G' in Figs. "A" and "B". On the upper side of "W" screw the rectangular piece of brass, 1x1⅞"; tap it to receive an 8-32 machine screw. Bend one edge of the blade at G down so the disc will not balk on starting past any switch contacts.

"C" is the turning rod, an 8-32 machine screw furnished with an insulated knob, indicator, and check-nut. Its length depends upon the thickness of the coil base.

It now remains but to assemble the parts. Drill a 3/16" hole through the base of the spark coil to receive screw "D." Push "K" under the springs as shown in Fig. "A." Screw all parts shown in "A" to the under side of the base of the coil, screw "D" down through "R"; screw on and tighten the check-nut. When the knob "D" is turned, six variations in capacity are secured. More can be had by adding additional spring contacts.

Contributed by
MAX EPSTEIN.



A ROTARY SWITCH TUNING COIL.

Those radio operators who believe in tuning coils will find the one described in the accompanying illustration of considerable interest, as the switch control is rotary in character, instead of the more crude "arm's length type," with sliders on bars. This design, here offered, is very efficient, both mechanically and electrically, and to give greater wave length range it may be made larger than here shown. The coil proper is made up on a wooden ring cut out by a fret saw from white pine, or other wood, to the dimensions given in Fig. 2. It should be sandpapered smooth, and the corners rounded. A coat of rather thickish shellac is given it; and, while yet slightly sticky, it is wound with one layer of No. 24 S. C. C. magnet wire.

The winding is done by first placing the wire on a small bobbin or stick, cut as at Fig. 2, B. If all the wire is inconvenient to handle at one time, it may be wound on in several batches, being sure to solder all the joints between various sections where the wire is joined. The coil should be well shellacked or, better, baked out in the oven with Sterling varnish after it is dry. The paths for the rotating arm contact wheels W, W, on arms L_1 and L_2, are sandpapered or scraped on the top and bottom of the coil. This coil winding is good for about 1,500 meters with ordinary aerial. Variable condensers will, of course, boost this wave-length figure.

The other details are perceived from the diagrams; the operating principle of the switches being that the smaller lever (L_2) rod rotates inside of a complete fiber or hard-rubber sleeve, with end washers, placed in the center of the larger moving shaft, which is threaded, as indicated, to receive suitable check nuts. A piece of 1/32 inch or 1/64 inch brass strip "X" is placed on the under side of the top cover, so that contact is made with the larger rotating spindle, S_1. Contact with the smaller spindle attached to lever (L_1) is maintained through the brass foot bearing and wire, as shown.

The whole instrument is mounted in a well-finished, hardwood case, or as the maker may elect. A hard-rubber top makes a fine appearance, and it only need be about ¼ inch thick or less, if backed by a piece of ¼ inch or ⅜ inch wood. Suitable dials are arranged for the needles (see Fig. 3) or indicators to pass over, the scale divisions being in degrees, etc. The scale for the detector circuit slider should be marked "Det." and the ground scale marked accordingly "Ground." Test the assembled shaft with 110 volts and a lamp to see that they are thoroughly insulated from each other. Diagram for standard connection are given at Fig. 4.

Easily Controlled Rotary Type Tuning Coil. Sliders are Secured to Center Knobs Fitted with Indicating Points and Scales.

Wireless telephony has been successfull tried out on D., L. & W. railroad expres trains.

The D. C. Arc for Wireless Telegraphy and Telephony

(Continued)

SLIDE 10. De Forest's method (see Fig. 9) is almost identical with that of Poulsen, except that he employs alcohol vapor in place of hydrogen.

The Dubilier System.

This is another hydrogen arc system based on the same principles. Dubilier employs an air-cooled arc, and the connections are so arranged that the oscillations of both the primary and secondary circuits pass across the arc. The connections are very similar to those used by the Anglo-French Wireless Co.

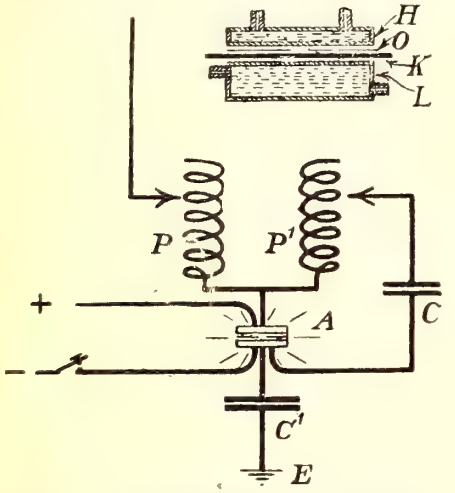


Fig. 12. The Lepel Quenched Arc High Frequency Generator.

Slide 11. We now come to a method of generating H. F. currents by means of a number of arcs in series in air (see diagram 10). This method is the outcome of the work of Duddell, Campos and Mosler. It has been thoroly developed by the German Wireless Telegraph Co. in Berlin. When a supply voltage of 220 volts D. C. is employed six arcs in series are required. On 440 volts twelve are necessary. The arcs are struck between water-cooled carbon anodes and carbon cathodes.

Fessenden.

We now come to the work of Fessenden. Those who have read the account of his lecture delivered to the American Institute of Electrical Engineers in 1908, will appreciate the enormous amount of work that he has done in connection with wireless telephony. In 1906 he constructed a H. F. alternator, suitable for wireless telephony. It was he who first used a microphone in the aerial circuit (see Fig. 11). In 1906, by the use of telephone relays of his own construction, he demonstrated the possibility of connecting a land telephone line to a wireless telephone station. I will read the following account from his lecture already referred to:

> "As it was realized that the use of the wireless telephone would be seriously curtailed unless it could be operated in conjunction with wire lines, telephone relays were invented, both for the receiving and transmitting ends, and were found to operate satisfactorily, speech being transmitted over a wire line to the station at Brant Rock, Mass., re-transmitted there wirelessly by a telephone relay, received wirelessly at Plymouth, Mass., and there relayed out again on another wire line."

These tests were witnessed on December 11th, 1906, by a number of scientific men, and reported in the American Telephone Journal. In 1907 Fessenden successfully transmitted speech between his wireless station at Brant Rock and a station in Jamaica, Long Island, a distance of about 200 miles. Fessenden has also invented a balance method of simultaneous transmission and reception.

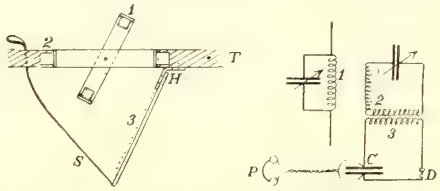
For the balance method he uses a phantom aerial; this circuit having such capacity, inductance, and resistance as to balance the radiating antenna; also an interference preventer, one of Fessenden's inventions, one side of which is tuned to a wave length of the distant transmitting station. The drawback to this method is that half the energy is lost, and the conversation is only half as loud as it would otherwise be.

At diagram 12 is represented the Lepel system. In place of a hydrogen arc, there is a form of quenched arc. The instrument consists of a sheet of copper and a sheet of delta metal, (both of which are water-cooled), between which is a sheet of thin paper perforated with a small hole at its centre.

This apparatus can be operated by alternating current, in which case it acts as a quenched spark-gap; or it can be operated directly from a constant current supply, provided that the voltage is sufficiently high to form a self-striking arc between the copper and delta metal electrodes. It may be connected to an inductance and capacity in a similar manner to that employed for an ordinary spark-gap, but in practice it is connected as shown, so that both the primary and secondary circuit oscillations pass across it.

The Anglo-French Wireless Co. own and operate this system.

Fig. 13 shows the receiving connections used by the Anglo-French Wireless Co. There is nothing extraordinary about the connections themselves. I am showing this diagram because I think the extremely neat arrangement for the inductance may be of interest. T is the top of a table; a large circular hole is cut at its centre and an inductance is wound in a groove cut in the piece of the table that was removed. This is then pivoted across the circular hole in the table. Inductance 2 is wound in a groove in the table top. Inductance 3 is wound in the form of a flat spiral, and the board on which it is wound is hinged



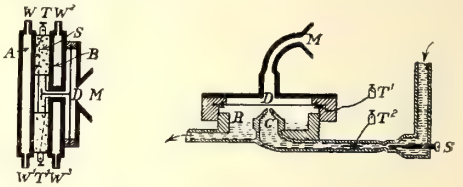


Fig. 13. Receiving Set Connections of the Anglo-French Wireless Co. Note Novel Coupler at Left.

to the underside of the table and can be pulled up and down from above by a strap S to alter the coupling. Inductance 1 is also turnable on its pivot, to alter the coupling.

The Morretti Arc.

There is another form of arc which I should mention, invented by Morretti. It consists of a copper tube supplied with water. An arc is struck between the water and a copper rod; it works on a high voltage direct current and the connections are the same as for a hydrogen arc. The oscillations are produced by a very rapid extinction and restriking of the arc, probably due to an action like that in a Wehnelt interrupter.

In conclusion, I should like to say a word or two as to the most suitable forms of microphones for wireless telephony, and just a word with regard to detectors and receiving apparatus. One of the greatest practical difficulties in wireless telephony has been to find a microphone capable of carrying a large current without becoming "packed" or overheated.

Fessenden's Carbon Grain Wireless Microphone.

Chambers' Liquid Microphone

Fig. 14. Two Types of Wireless Telephone Transmitters.

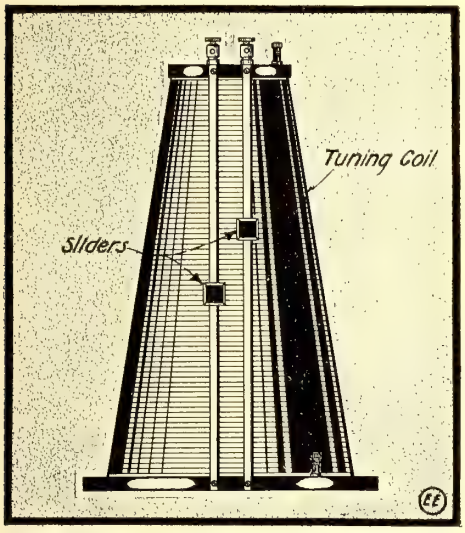
When dealing with a small amount of power, as I have been this evening, an ordinary "solid back" microphone answers quite well; but this is unsuitable for use with large currents. One way of getting over the difficulty is to connect a number of similar microphones in parallel, with all their mouthpieces connected to one trumpet. This method, however, is not thoroly practical, as the conductivity of each microphone varies from time to time and there is the likelihood of one or more of them overheating.

Fessenden in 1906 invented the first really practical carbon grain wireless microphone, which he claims will carry a current of 15 amps., without packing. The figure on the left-hand side of this slide (Fig. 14) shows the construction of the instrument. The carbon grains are held in a small chamber cut in the centre of a disc of soap-stone "S." Two platinum electrodes at the back and front of the chamber are water-cooled. A small rod passes through a hole in the front water-cooling tank and electrode, connecting the diaphragm D to a small spade or plunger in the centre of the grain chamber, which is only half filled with carbon grains by the way.

Dubilier uses a somewhat similar microphone.

The diagram on the right-hand side of this figure shows a Chambers' liquid microphone. This is another form of microphone. A small jet of acidulated water passes through a nozzle C and plays upon the underside of the diaphragm. When the diaphragm vibrates there is an alteration of resistance of the liquid at this point.

(To be concluded.)



NORRISTOWN RADIO CLUB.

The amateur radio operators of Norristown, Pa., have organized and call themselves the Norristown Radio Club. The officers elected were: Earl Moore, president; Wilbur Heiser, vice-president; Charles Wolfe, secretary; Randolph Roland, treasurer, and Samuel Place, consulting engineer. The club would like to hear from such associations. Norristown Radio Club, Main street and Franklin avenue, Norristown, Pa.

RANDOLPH ROLAND,
Treasurer.

IMPROVED CONICAL TUNING COIL.

A decided improvement, which is not very well known, by the way, in the design and construction of tuning coils for use in wireless receiving sets is shown in the illustration. The improvement, in general, is based on the fact that with a tapered or conical coil it is possible to greatly increase

Conical Form of Tuning Coil, Equally Efficient on Long and Short Waves.

the flux density in the region of the lesser diameter turns on the coil when only a small inductance is used in picking up a certain signal coming in on a short wave length. When a longer wave length is being received, any part of the coil can, of course, be used. The idea, of course, to be followed is always to include as much as possible of the smaller end of the coil. It will be evident at once that when short wave lengths are being received much greater efficiency in the instrument will be the result when the turns of wire are small. This is the reason why extra large loose couplers and tuning coils are very inefficient on small wave lengths where only a few turns of wire can be used.

A common form of conical tuning coil is, as shown, provided with two sliders. The wood form on which to wind the wire may be turned in a lathe or can be made up at any cabinet maker's for a few cents.

It may be suggested that the conical form on which to wind the wire be made about 2½ inches diameter at the small end and 6 inches diameter at the larger end. It can be 11 to 12 inches long and wound with one layer of No. 24 enameled magnet wire. The wire, of course, is scraped or sandpapered free of insulation in the two paths where the sliders are to make contact. It is connected as usual in the radio receiving circuit.

TO FORM RADIO CLUB.

In December last members of the Y. M. C. A. branch at Asbury Park, N. J., interested in wireless telegraphy assembled for the purpose of organizing a wireless club. Jewell VanDyke and Harold Warren supervised the club. It is the purpose of Mr. Warren to teach the wireless code to the members, and there is no doubt but that within a short time the members will be able to receive messages nicely. During the past few weeks experiments carried on by Warren and VanDyke have in a large measure been successful, and messages are constantly being received. Mr. VanDyke is connected with the VanDyke Electric Company.

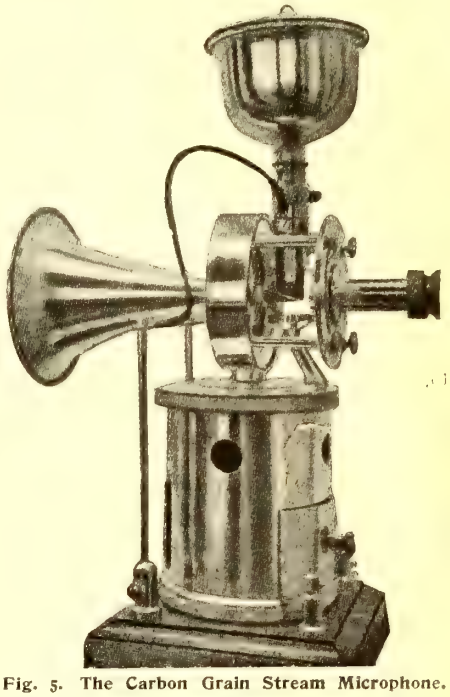
Novel Wireless Telephone Microphone

An ingenious wireless telephone microphone designed to carry several amperes, and which does not heat unduly or "pack," as ordinary carbon grain microphones tend to, is described by Mr. Scheidt-Boon in T. S. F. Our cuts of the instrument show clearly its novel means of handling heavy radiophone currents without over-heating.

Referring to the diagram we perceive at Fig. 1 a cross section view of the "continuously renewed" carbon grain microphone. Into the hopper (5) is placed a quantity of carbon grains which, of course, drop down and against the valve at 9. This valve (9) is mounted on a pivoted beam or lever (3), so that the two magnet coils (1, 1) can act on the iron armature secured to the end of the lever. The cup (10) catches the carbon grains as they fall through the opening (9).

The valve (9) may be arranged in different ways, as at Figs. 2 and 3, Fig. 2 being an angular valve and Fig. 3 a conical seat.

Now the action of the microphone will be readily understood from Fig. 4. Here an ordinary microphone (16) creates varying electric currents through the primary circuit (17, 18, 19, 20) of an induction coil. The secondary circuit (21, 22, 1) thus causes the magnets to exercise a varying magnetic pull on the lever (3), which is mounted on a circular metal diaphragm, and which vibrations correspond with the voice undulations occurring at (16). Hence the vibratory movement of the lever and valve (9) will cause a changing quantity of carbon grains (with consequent varying resistance) to pass through and between the two electrodes 23 and 24 (Fig. 4), which will thus vary and control the aerial oscillating current. The source of high frequency aerial current is not shown, but it may be a radio-frequency alternator or a Poulsen arc generator.



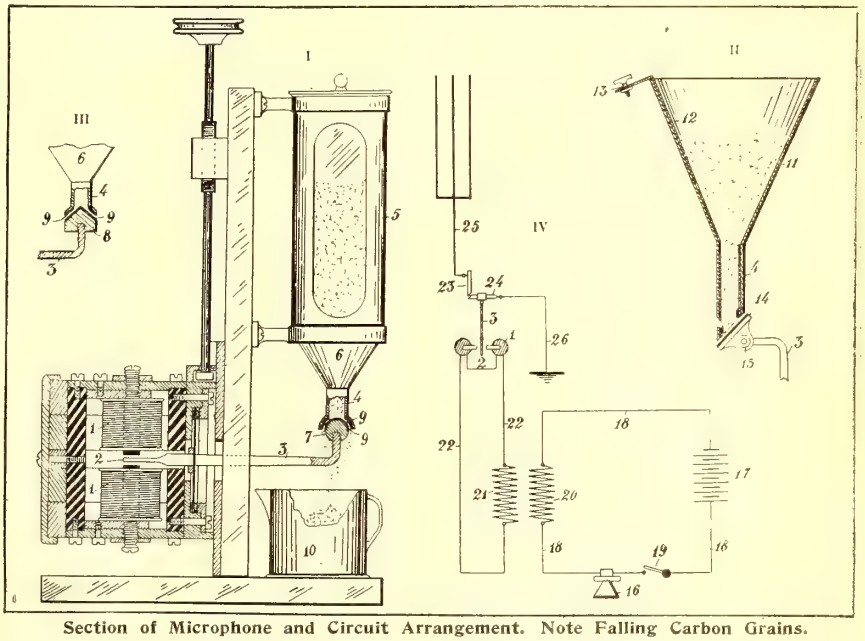


Fig. 5. The Carbon Grain Stream Microphone.

Section of Microphone and Circuit Arrangement. Note Falling Carbon Grains.

Fig. 5 is a photographic illustration of the device just described. The large horn to the left leads to the microphone, while the cup-shaped piece at the top contains the carbon grains.

YOUNG MARCONI RADIO CLUB.

The "Young Marconi Radio Club" met at the home of Albert St. Cyr, Jr., 319 Harrison St., Marquette, Mich., and an election of officers took place. The officers are as follows:

President and Secretary, Albert St. Cyr, Jr.; Vice-president, Herman Bittner; Treasurer, Edward Lundstrom; Chief Operator, Walter Frie; Assist. Operator, Will. Gasper.

We would like to correspond with other clubs.

ALBERT ST. CYR, Jr.,

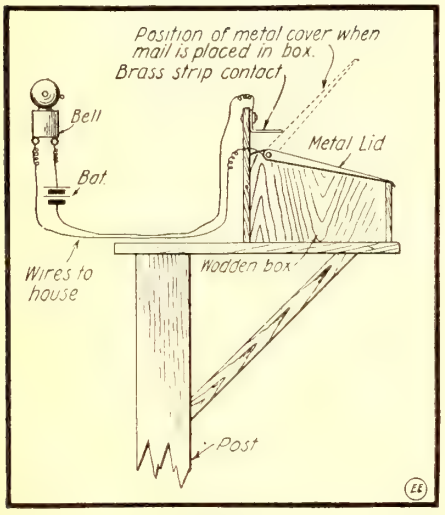
COLLEGE RADIO CLUB NEWS.

At the last meeting of the Club, an election of officers for the ensuing year resulted as follows: Wm. C. Nolan, president; Earl S. Shader, vice-president; Phil W. Pelts, secretary, and O. C. Pavia, treasurer. Jack Forsythe is stenographer. Several new members were admitted and a plan for the year's work outlined.

PHILIP W. PELTS, Secretary, 612 Adams Avenue, Memphis, Tenn.

A round magnet coil contains the least resistance with a given core section.

HOW-TO-MAKE-IT DEPARTMENT



This department will award the following monthly prices: FIRST PRIZE $3.00; SECOND PRIZE $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

FIRST PRIZE $3.00.

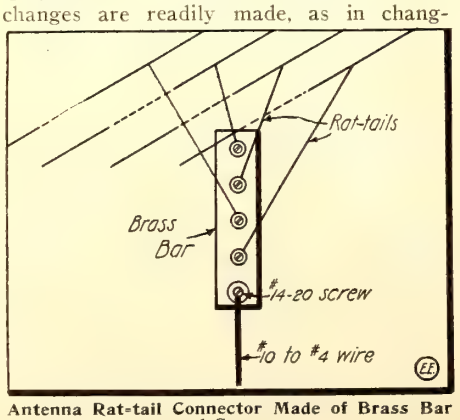
RURAL MAIL BOX ALARM.

I herewith give a suggestion which I am sure will meet the eye and taste of everyone living in a rural district where the mail is placed in a wooden box fastened on a post by the roadside. The purpose of my suggestion is to have an announcing bell at the house when the mail is placed in the box by the mail carrier and thus make a long wait unnecessary. The only article necessary is an electric bell which may be bought at any store for 25 cents. A roll of insulated bell wire must also be used. To furnish the current two or three dry cells are to be procured. Two cells will be sufficient for any distance up to 200 feet. Cut one thin brass strip, as shown in illustration, and also procure a metal lid to form a cover for the box. Both brass strip and metal cover are each put in connection with two copper wires strung to the house. The wires are simply tacked (by staples) on small posts driven in the ground, and the rest of the wiring, as shown in diagram, is very simple. The idea of this arrangement is as follows:

As soon as the mailman lifts the lid and places the mail in the box the metal lid comes in connection with the brass or metal strip and it causes the bell in the

First Prize: Rural Mail Box Electric Alarm Bell.

house to ring as a signal that the "mail has arrived." Submitted by



WILLIAM WARNECKE, JR.

SIMPLE ANTENNA CONNECTOR.

A very simple and efficient antenna rat-tail connector is illustrated below. This is made up from a piece of copper or brass bar about ½ by ¼ by 2½ inches. Four or more No. 8-32 machine screws are tapped into the bar, and these are furnished with washers under the heads, enabling the No. 14 wire rat-tails from the aerial flat-top to be clamped securely.

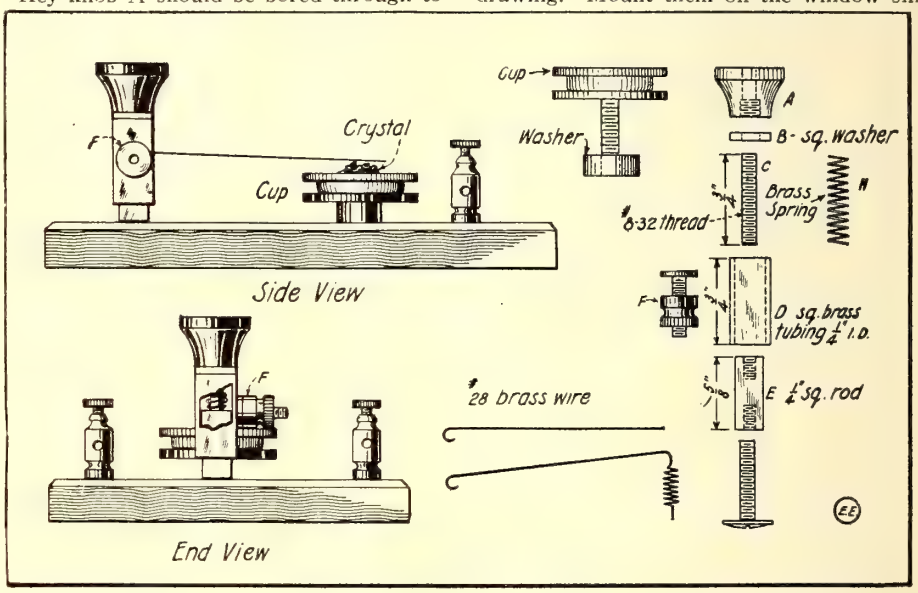
At the base, where the main lead-in wire or cable goes down to the instruments or lightning grounding switch, a heavier machine screw is fitted on the bar. This may be about No. 14-20 size machine screw.

If the lead-in wire is larger than No. 10 B. & S. conductor it is best to screw a lug under this screw and to sweat the large wire into the lug with solder. The rat-tails are usually tapered down to the connector for a distance of 10 to 20 feet. One feature of such connectors is that changes are readily made, as in changing from looped to straight-away system.

Antenna Rat-tail Connector Made of Brass Bar and Screws.

SECOND PRIZE $2.00.

UNIVERSAL CRYSTAL DETECTOR.



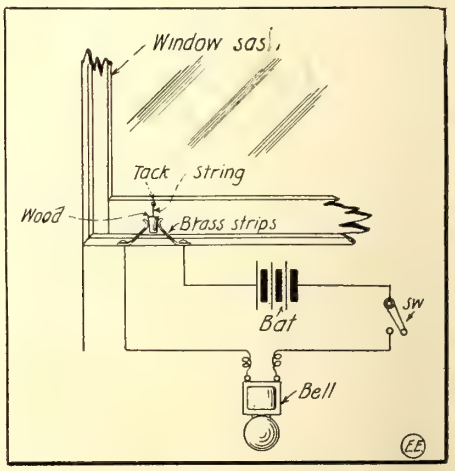
The following notes, in addition to the drawings, will explain the construction of this crystal detector. All materials not on hand can be bought at a nominal cost.

Key knob A should be bored through to the brass bushing to permit the passage of the threaded piece C. A square brass washer, B, is soldered on top of D and the binding post F to the side of D. This binding post can easily be made by filing down the head of a binding post taken from the zinc side of a dry battery. The square rod E is drilled and tapped at both ends to admit an 8-32 thread.

"Electro" sliding cup and slide make a very satisfactory device for holding the crystal, as the contact wire slants down to it, the pressure being regulated both by the knob and by sliding the cup.

This detector is adaptable for use with all crystals employing a wire contact for their operation.

Contributed by W. H. HALE.



Second Prize: Clever Radio Detector for Using Galena and Other Minerals.

THIRD PRIZE $1.00.

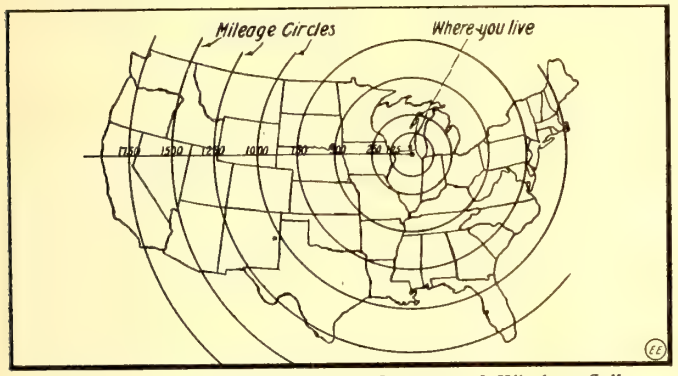
NOVEL BURGLAR ALARM.

Herewith is a plan for a simple electric burglar alarm.

First, get two pieces of springy brass and bend them to the shape shown in the drawing. Mount them on the window sill so that the top part of each are touching together. Put a small strip of wood between them where they touch. Drive a small tack in the upper end of the strip of wood. On this tie a string, also attached to the window sash.

Third Prize: Electric Burglar Alarm for Windows.

When the window is raised it pulls the strip of wood from between the brass strips. This closes the circuit and rings the bell until it is turned off by a switch.



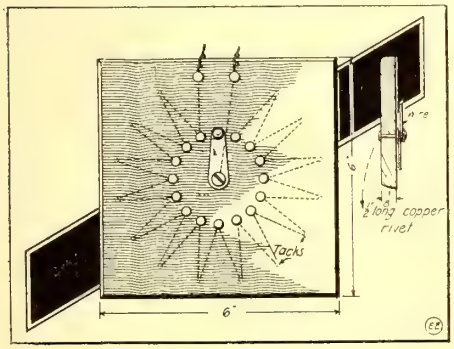
Contributed by HARRY HARVEY.

RAILROAD WIRELESS.

L. B. Foley, superintendent of telegraph, telephone and wireless, Lackwanna Railroad, New York, accompanied by Dr. Lee de Forest, left for San Francisco recently, to look into the merits of the Poulsen continuous wave system.

WIRELESS RANGE MAP.

Here is a diagram of a map that will help wireless operators a great deal. As I am a wireless operator, I find this map very useful in determining the distance between the sending station and receiving. I thought you might wish to publish it in your valuable paper, *The Electrical Experimenter*:



Range Map for Instantly Locating Distance of Wireless Calls.

First, I made a map of the United States; then I made circles, with *Malta*, Ill., as the center, because I live here, but the person who makes one must make his home the center, in order to find the distance in miles in all directions without any difficulty and at a glance tell the distance of the other station which is sending. I find it is very useful.

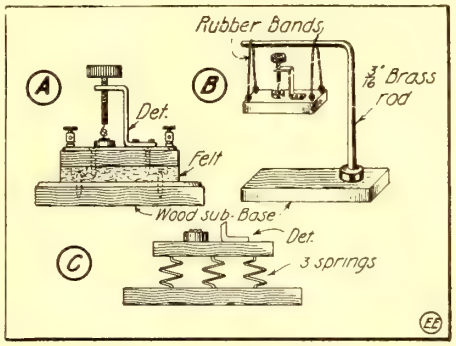
Contributed by WILBUR PHELPS.

HOME-MADE RHEOSTAT.

This is a description of a home-made rheostat: Make up a piece of wood 6x6 inches and ⅜ inch thick. Find its center and circumscribe a circle with a radius of 1⅛ inches. Lay off 18 points on this circle and on every point drill a little hole through the board, except the two points on the upper side of the board. After this take 16 ½-inch copper rivets and put them in the holes. Turn the board upside

Rheostat Composed of Few Feet of Resistance Wire and Copper Rivet Switch Points.

down and lay on every rivet a copper washer. Now get some high-resistance wire, such as iron, German silver, etc., attach on the first rivet and lay out at a sharp angle to the outside on the board and wind it in nearly two turns around the second rivet, and so on till the last rivet is finished. Now get a switch lever and attach to the center of the board. On the top of the board attach two binding posts: from one binding post connect a wire to the switch lever beneath the board; from the other binding post run a wire to the first copper rivet. Now lay on every copper rivet a washer and hammer the rivets down and the wire will fit tightly between the two washers. At last the whole board should be painted with a nice-looking color of paint. This little rheostat can be made at a very low price.



Contributed by JOHN BLANKE.

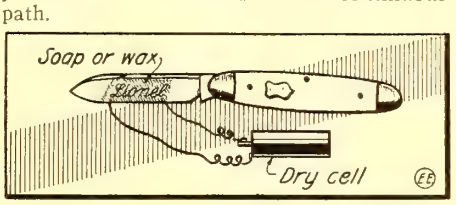
NON-VIBRATION MOUNTING FOR DETECTORS.

One of the principal troubles encountered when using wireless detectors of the ordinary type, such as those with delicate "cat-whisker" wires on them, etc., is that they are subject to vibration from tables, or even the building in which they are located. To overcome these troubles several schemes are shown in the sketch herewith.

At A the detector is so mounted on a piece of thick felt that no solid connection results between the base of the detector and the wood or other sub-base, which may be the table top.

A simple scheme to apply, and very efficient also, in the elimination of vibration transmission is that outlined at B, where the detector base or piece of wood fastened under its base has say, four small screw-eyes fastened at the corners of the same, with some rubber

Three Methods of Mounting Detectors Free from Vibration.



bands fastened over the brass arm as shown, so that the detector swings on the rubber bands.

Another simple way of overcoming vibration in the detector is to mount the base of same on three or four springs, as outlined at C in sketch.

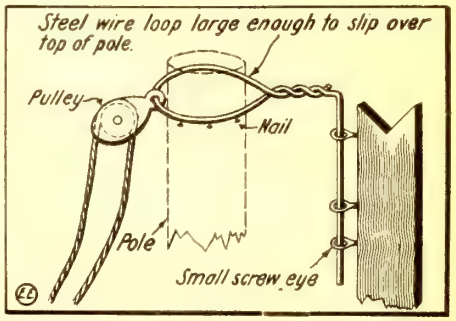
ELECTRO COPPER COATED ETCHING.

Take five cents' worth of blue vitrol stones. Dissolve in one part of water and add two tablespoonfuls of salt, which makes the etching fluid.

Now, for the object to be etched: Take a knife blade, for instance. Take a piece of yellow laundry soap and rub on the knife blade until a thin coating is on the knife; then, with a sharp-pointed pencil or pin, scratch your initials or any other object on same. It should make a continuous path.

Copper Etching on Steel Blade.

Now pour the liquid just prepared on the blade until entire initial, or other object, is covered.



Take a common, dry battery and lay both wires in the liquid and leave for about two minutes.

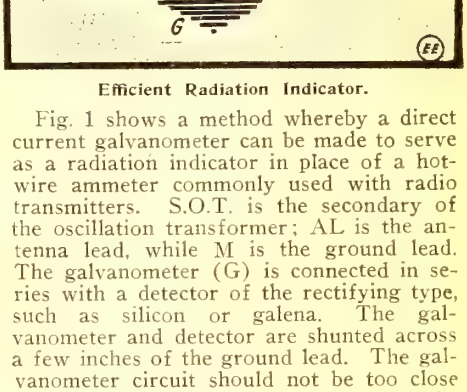
Then rub soap off and you will have the initials, or other object, copper-coated and also etched into the knife blade.

Contributed by LEO G. DRISCOLL.

AN AERIAL POLE WRINKLE.

While it does not often occur, I should think somebody besides myself has had or perhaps will have trouble with the rope breaking or jumping the pulley on an aerial mast.

Simple Way to Arrange Aerial Pulley for Removal of Rope.



Recently I put a 35-foot pole in my yard, and the rope jumped the pulley, which kept it from being moved either up or down. I broke the rope in the attempt and thought it necessary to take the pole down, although it was firmly guyed. I at last devised the little scheme shown in the drawing, and with three clothes props and a little wire replaced the pulley with a new one threaded with new rope. Submitted by

RANDOLPH ROLAND.

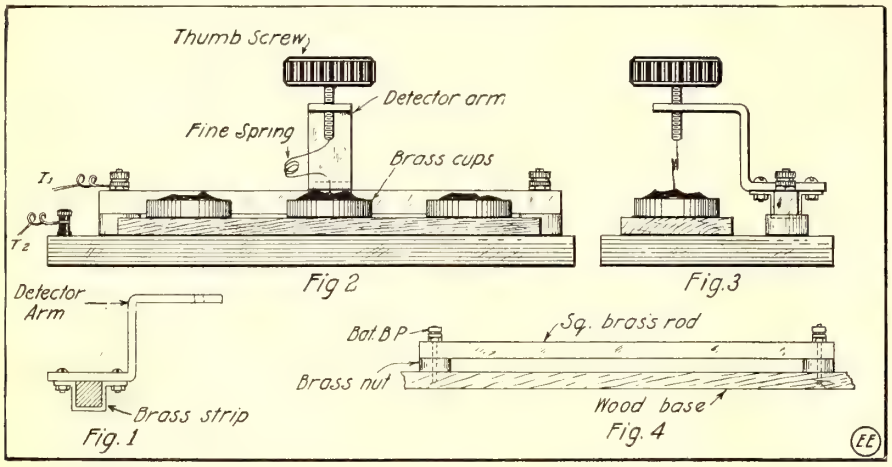
THE GALVANOMETER AS A RADIATION INDICATOR FOR RADIO TRANSMITTERS.

By Wm. H. Dettman.

Nearly all sensitive galvanometers are only capable of responding to direct currents or to alternating currents of very low frequency, and therefore cannot be used in the regular way for measuring high frequency currents such as are utilized in wireless telegraphy.

Efficient Radiation Indicator.

Fig. 1 shows a method whereby a direct current galvanometer can be made to serve as a radiation indicator in place of a hot-wire ammeter commonly used with radio transmitters. S.O.T. is the secondary of the oscillation transformer; AL is the antenna lead, while M is the ground lead. The galvanometer (G) is connected in series with a detector of the rectifying type, such as silicon or galena. The galvanometer and detector are shunted across a few inches of the ground lead. The galvanometer circuit should not be too close to the transmitter. The detector must be adjusted to sensitiveness in the same way as when used with a receiving set; while making these adjustments the hand should not come in contact with any metallic parts of the detector, as this will interfere with the reading.



The above resonance indicator is superior to the hot wire meter in that it does not increase the resistance of the aerial circuit as the hot-wire meter does.

A NOVEL THREE-CUP DETECTOR.

Procure a piece of square brass rod ¼" square and 5" long and a detector arm including the thumbscrew.

A detector arm may be taken from an old detector which is not in use or may be purchased. The kind used on the "Electro" galena detector is very good.

Next, get a brass strip 1¼x¼x1/16" and bend it around the rod and fasten

Any Mineral at Once Available by Simply Moving the Vertical Arm Along the Slider Box.

to the detector arm as shown in Fig. 1.

The brass strip must not be so tight as to hinder the arm from sliding along the rod. A hole should be bored in each end of the rod and two holes in the base the same distance apart as those in the rod. The rod should be elevated from the base by placing a nut between the base and rod. Then the battery binding posts are inserted in the holes and tightened as shown in Fig. 4.

The base, which is 6x3x⅜", should be of fibre, but hardwood may be substituted.

Get three brass cups from the carbons of old batteries or they may be purchased from any supply house.

Get a wood or fibre block 4x1x¼" and bore a hole ½" from each end and one in the middle, just large enough so the cups may be pushed snugly into the holes. Screw the wooden block to the base under the thumbscrew and parallel with the brass rod, as shown in Fig. 2.

Then get three different minerals, for instance, silicon, galena and molybdenite, and place one in each cup. They may be fastened in same by packing tinfoil around them or by Hugonium Alloy. Connect all the cups together and to a binding post T_2.

Then connect the brass rod to another binding post T_1, and it is complete.

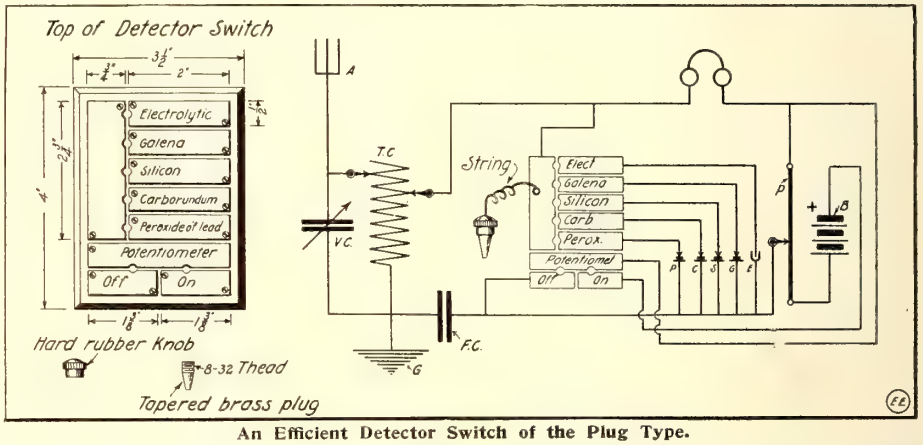
If you wish to use galena, you may slide the arm along until it is along side the cup in which the galena lies, etc.

More cups may be used, but the detector must be made longer according to the number of cups used. This detector saves the trouble of having more than one complete detector and a switch for them.

Submitted by
SHERMAN APPLEGATE.

A PLUG TYPE DETECTOR SWITCH.

The accompanying plan and description are of a very practical detector switch which the writer recently made, and is sending along for E. E. readers.

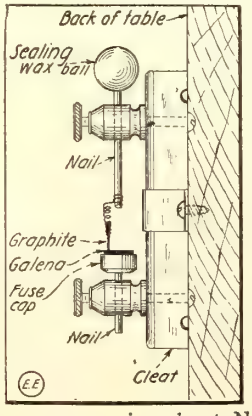


The switch is made of sheet brass and connections are made by means of small brass plugs.

The brass should be about No. 20, and the pieces mounted on a base, leaving 1/16" between them. The wires are soldered to the brass plates on the under side; thus making a very neat instrument.

The diagrams are self-explanatory and carry all necessary dimensions. Everything required may be procured from any electrical supply house.

If desired, each plate may have its corresponding detector name, etc, etched on them by coating the plates with wax, scratching the name in same with a sharp instrument and filling the grooves in the wax with acid. Afterward the etched grooves can be filled in with black enamel and the plate surfaces polished and lacquered.



Submitted by
JAMES L. GREEN.

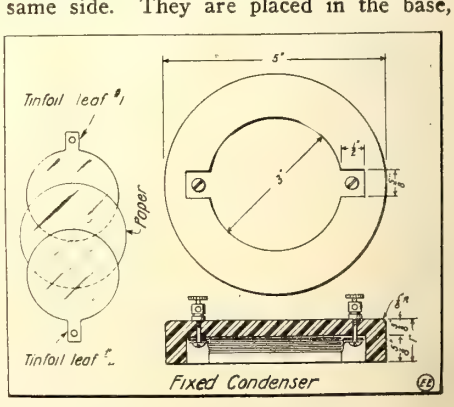
An Efficient Detector Switch of the Plug Type.

A SIMPLE WIRELESS DETECTOR.

After some experimenting with detectors, I evolved one, cheap and easy to construct, and hard to beat for sensitiveness and ease of adjustment, factors necessary in long distance receiving.

I have given a sketch showing its construction. Merely a two-wire cleat, two ordinary binding posts, two 8 penny nails, a brass cap from a fuse, some sealing wax and a short piece of lead from a hard lead-pencil; also a few inches of spring or copper wire about No. 30.

These are assembled according to the drawing. The two posts are mounted in the holes in the ends of the cleat, then cut one nail off 1" from the head, solder brass cap to it, cut other nail off about 2" from head, dip the head in melted sealing wax and turn it slowly; this will form a handle. Make connections to back of posts, then clamp cleat against back of table with a brass strip ½" wide, slip shorter nail with cap into lower post, slip other nail in upper post, then fasten the lead to the upper nail by means of some fine wire. Place a piece of galena in the cup and pack it tight with small wads of tinfoil and adjust.



It is important that the lead have a very sharp point touching the galena.

Contributed by
THOS. W. BENSON.

A RADIO BLOCKING CONDENSER.

Here is a description of an effective fixed or blocking receiving condenser. The wood used in the construction of this condenser is preferably one that takes a high polish, such as mahogany or oak. A circular piece of wood 5 inches in diameter is turned up with a hole in the center 3 inches in diameter, having a depth of ¾-inch. Slots on the side of this are made to allow space for the lugs of tinfoil and the binding posts.

Twenty sheets of tinfoil are cut out with a diameter of 2½ inches, having lugs ⅝-inch wide and ½-inch long. Twenty-one circular pieces of paraffin paper are made 2¾ inches in diameter. The tinfoil and paper are placed alternately upon each other, so that every other lug lies on the same side. They are placed in the base,

Blocking Condenser Made from Tinfoil and Paper in Circular Wood Base.

binding posts are inserted and the remaining space is filled with paraffin.

The dimensions are given in the diagram.

This condenser presents a neat and pleasing appearance and is a valuable addition to any receiving set.

Submitted by PERCY M. ROOPE.

U. S. PATENT OFFICE

IMPROVED SELENIUM CELLS.

In an article in the *Physical Review* Mr. D. S. Elliott describes a new construction of selenium cells, due to Pfund. It is particularly adapted for low-temperature work. Amorphous selenium was first cast into discs about 1.5 cm. in diameter and 1.5 mm. thick. They were sensitized in the usual way, being maintained at a temperature of 200 deg. C. for six hours and then cooled rapidly to room temperature. The

Fig. 1.

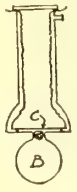


Fig. 2.

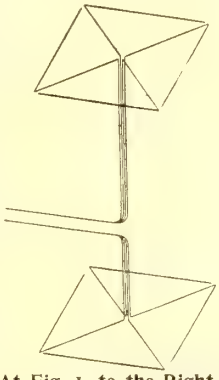
discs were then ground smooth on crocus cloth, after which silver tape electrodes were fastened on with celluloid. A film of gold was next deposited by cathode sputtering, and finally the gold was removed along a narrow line like a grid as shown in Fig. 1. No deleterious action due to mercury vapor could be detected. The cell was finally inclosed in a glass tube similar in design to that shown in Fig. 2. The smaller bulb was filled with calcium chloride and the constriction leading to the upper chamber was loosely plugged with cotton. The cell was fastened with sealing wax in this upper chamber, the end of which was closed by a glass plate. The vessel was also provided with a side tube for exhausting by means of an aspirator, a phosphorous pentoxide tube being inserted between cell and aspirator during the process.

IRON CONDUCTORS INSTEAD OF COPPER.



The present European war brings to the front the somewhat unfamiliar idea of using iron and steel wires for overhead conductors and even for other purposes. The effect of the war in cutting off the importation of copper from Germany has been considerable—just how great it is quite impossible to tell, but great enough to raise the question here discussed. Tests made both for direct current and alternating current have shown that in using relatively small wires with low-current densities the iron conductor can be made surprisingly effective, even for alternating currents, when the matter of cost is taken into account. So effective is it, indeed, that at a possible ratio between the cost of iron and that of copper; conductors of the former material may pay well. It is only when the conductors are of the larger diameters and carrying considerable current that the serious effects of the change in material become conspicuous. While at home the cost ratio of iron as compared with copper is unfavorable, yet, if a recent quotation reported from Germany of $600 a ton be correct, the balance may well be turned in the other direction.—*Electrical World.*

TIME-FACTOR IN SELENIUM RESISTANCE.

The Time-Factor in Selenium Resistance is covered in the "Physical Review" for Sept., 1914, in an article by G. E. Grantham. It is well known that the electrical resistance of selenium does not reach an equilibrium value instantaneously after exposure to light, and the rate of change of resistance on exposure is much greater than the recovery rate. The problem suggested the use of a rotating disk from which sectors are cut to allow the light to fall upon the cell, the cell being in one arm of a Wheatstone bridge with some device for connecting a galvanometer in the bridge circuit at a known time interval after exposure. The author describes experiments made by this method. The relation between time and resistance for the preliminary experiment is shown in curves. During the first hour the rate of change of resistance increases with the speed. During the remainder of the time the cell approaches the equilibrium resistance. This equilibrium resistance is the resistance of the cell at the time that the decrease on exposure is just equal to the increase in the dark. A discussion of the results is given on the assumption that selenium consists of three components.

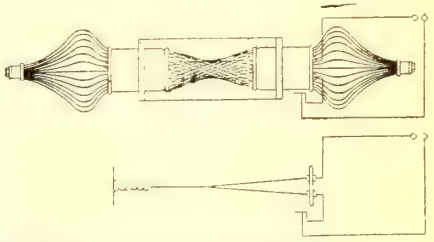
INTERNATIONAL COMMISSION ON RADIOTELEGRAPHY.

Below we give part of a discussion by William Duddell of the proposed work to be undertaken by the International Commission on Wireless Telegraphy. At the sending station it is necessary to measure the antenna current, which requires ammeters suitable for high frequencies and strong currents up to 150 amperes at least. Hot-wire instruments must be used. The author proposed the arrangement shown in Fig. 1. It consists of two copper tubes, on each of which a series of notches is made. A thin wire passes in zigzag fashion from one notch to another, as shown in the illustration, so as to form a kind of squirrel cage. The two tubular electrodes are given a rotary movement with regard to one another, causing the wires to fall on the surface of a hyperboloid of revolution. Two wires are stretched along the axis of the hyperboloid and joined together in such a way that the weld (giving a thermocouple) is at the central part of the narrowing or contraction. These wires are taken to a millivoltmeter. With an instrument of this kind an e.m.f. of 5 millivolts is obtained when a current of 150 amperes passes. The nature of the antenna to be used at the control station requires very careful consideration, in order that changes, for instance, in the earth may not affect the accuracy of the results. Probably Lodge's type of antenna, as shown in Fig. 2, is best. On the other hand, it might be well to see whether a receiver with closed circuit, such as has been described by F. Braun, might not be better. Among its other advantages is the fact that the properties of the circuit could be defined very exactly and kept constant. At the different receiving stations it is necessary to determine the strength of the signals that are received, partly with a view to comparing results from day to day and partly to compare the results which are obtained at the different stations on the surface of the earth.

At Fig. 1, to the Right, New Form of High Capacity Hot Wire Meter. At Fig. 2, to the Left, Lodge Balanced Antenna Proposed for Quantitative Test.

Electricity is used to locate the bullets in the European war victims.

ANENT THE TUNGSTEN LAMP.



Four years ago three carbon lamps were sold for every Edison mazda lamp; to-day 12 Edison mazda lamps are sold for every carbon lamp. If all the filaments used in the Edison mazda lamps manufactured in 1913 were made into one length they would stretch for 50,000,000 feet, or nearly half way around the earth, says the *Edison Business Builder.*

WEAR ON OVERHEAD TROLLEY WIRES.

An illustration of the wear which takes place on overhead trolley wires occurred on the Blackpool Corporation Tramway system (English) recently, when a length of nine miles of wire was renewed. A one-yard length of the old wire, which has been in use 12 years, was found to have lost 55 per cent. of its original weight, says *The Electrician,* London.

SOME "ENGLISH" SHORT CIRCUITS.

Contributions to this section (in the shape of definitions of well-known electrical objects) are invited from the witty members of the industry, says *The Electrician,* London. "Hot plates" will be awarded from time to time for the best efforts, and we give below some of the first efforts:

D. C. Turbo-Generator: A machine with a past, valueless as a present, and without a future (try A.C. Turbo-generator).

Gas Engine: A mechanical monstrosity, of which it has been rightly said that the connecting rod is often in doubt as to the direction it was intended to take.

Centrifugal Pump: The practical embodiment of the science of rotating squirts.

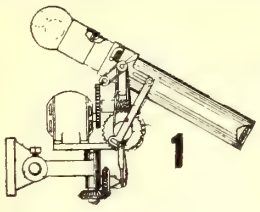
Wattless Currents: The fruit of the Watt-le (see also What'll ye have).

Professor: One who professes something, sometimes to teach, more often to know. May also act as consulting engineer.

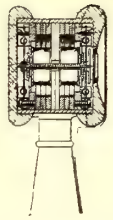
Dry Cell: A cell which is of no use unless it is kept moist (vide Scotchman).

Commission: Money paid not willingly, but grudgingly and of necessity.

[Ed. Note.—*What have our readers to say? Suppose you think up a few good electrical definitions on this order. If good enough we will publish them.*]



THE COOPER HEWITT MERCURY OSCILLATOR.



Dr. Peter Cooper Hewitt has announced completion of the preliminary work on a new development of his well-known mercury-vapor lamps and rectifiers. The new inventions involve improvement on the vacuum-tube rectifier for feeble high-frequency currents, such as occur at the receiving station of a radio-telegraph or radio-telephone system and the development of an oscillator or converter which efficiently transforms direct current or low or high voltage into sustained

(*Continued on page* 27.)

ADVERTISING LAMP (Fig. 1)—A motor continuously moves the lamp tube up and down; the tube projecting an image on the sidewalk, etc.

TELEPHONE RECEIVER (Fig. 2)—Novel receiver in which opposite balancing effect acts on spring-supported armature. Two magnet coils are used.

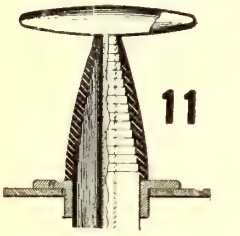
ELECTRIC AUTO SIGNAL (Fig 3)—A rear signal for autos, comprising arrow heads illuminated when auto is to turn corners. Center lamp lights license number.

ELECTRIC RELAY (Fig. 4)—A relay comprising a diaphragm for receiving vibrations, and a fluid medium for transmitting said vibrations from said diaphragm to secondary circuit.

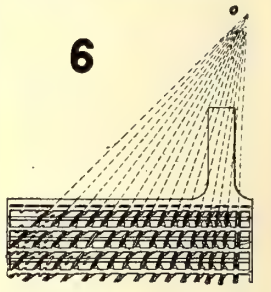
BATTERY CONNECTOR (Fig. 5)—Improved connector cable and lugs with split springs, preventing nuts from vibrating loose.

STORAGE BATTERY PLATE (Fig. 6)—Scheme to have all vertical ribs in plate point toward a hypothetical center of electrolysis distribution, O.

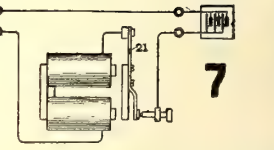
A. C. VIBRATING RECTIFIER (Fig. 7)—Has a vibrating armature, 21, corresponding in period to the A. C. frequency. Hence will pass + and miss — waves, and deliver D. C. to storage battery, 7, etc.



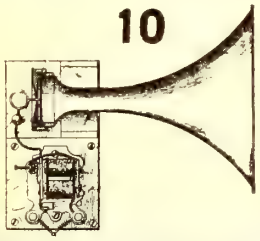
MAIL BOX ALARM (Fig. 8)—Alarm with bell, switch and battery. Closed cover tell-tale, rings bell and moves indicator to read "Mail."



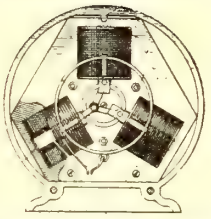
CURIOUS ELECTRIC MOTOR (Fig. 9)—Three suction type electromagnets act on crank pin disc alternately to rotate shaft. Includes switching gear.



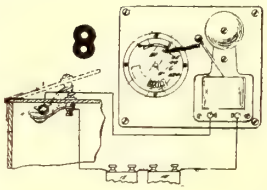
ELECTRIC HORN (Fig. 10)—Simple horn, actuated by electric buzzer joined by resilient spring between armature and horn diaphragm.

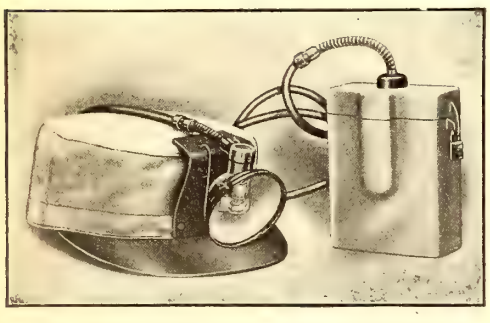


NOVEL ELECTRIC INSULATOR (Fig. 11)—Terminal insulator with condenser leaves wrapped around it, shaped to conform to electrostatic field about it.



ELECTRO-PNEUMATIC SOUND BOX (Fig. 12)—A blast of air is fed into the lower pipe. Electromagnet actuates a gate valve. Escaping air vibrations pass out horn, B, giving rise to sound. Amplifier principle.





ELECTRIC HEADLIGHT FOR MINERS.

The miner of this era has a much more efficient and agreeable source of light available than his brother of other days. Then it was the oil lamp, with its attendant odors and unsteady, flickering beam. The modern electric miner's headlight is a great boon, indeed. A typical form of standard

Electric Headlamp for the Miner. Storage Battery Supplies Current.

equipment for these requirements is here illustrated.

The battery used is a small storage cell of several plates, placed in a leak-proof, vulcanite container or tank. Two wires lead up from the battery, placed at the miner's waist in the rear, to the headlight arranged for fastening to his cap, as shown. Suitable switch is provided to open and close the lamp circuit. This outfit is highly developed in its details so no undue trouble will be experienced from acid leaking out of the battery, etc. The terminals of the battery are so made as to be acid- or corrosion-proof. Hundreds of the batteries are charged at one time in a battery house. Usually the cells are joined in series while charging. One charge will last a day.

Do You

realize that there are over 75 original articles and over 100 original illustrations in this magazine.

THE NEXT ISSUE WILL BE ENLARGED AGAIN

and many new and original features will be found in it.

The Subscription Price of this journal will go to $1.00 shortly. It is to your interest to subscribe to it now while the price is so low.

THE ELECTRICAL EXPERIMENTER is the greatest value today in Electrical Literature. If you intend to subscribe to it, do it now. One year, 50 cents; 2 years for $1.00, 3 years for $1.50, 5 YEARS FOR $2.00. (Foreign postage to be added.)

HAVE YOU AN IDEA?

Are you using a new device or an improved modification of such, in your wireless or electrical laboratory? If so, why not write it up and send to us with a photo or sketch? Drawings invariably have to be made over by our draughtsmen, and just so you express your ideas concretely and as briefly as possible, we are always glad to publish them, when the article possesses merit. Look over this issue carefully, re-read the articles twice, and you will soon pick up the knack of writing articles, and, moreover, we pay you well for your efforts. Why not get busy to-day and get in the swim? Be a live, wide-awake Electrical Experimenter! Boost your paper and boost yourself. It's very easy!

Make all sketches on separate sheets of paper, and write only on one side of your text sheets. Address the Editor.

HOW TO BIND "ELECTRICAL EXPERIMENTER" COPIES.

A simple method to bind copies of the *Electrical Experimenter* together is as follows: On the side where the leaves of the magazine are bound together punch two holes, one at the top and one at the bottom. Do this to all of the magazines and then put ordinary paper fasteners through these holes and bend the ends over.

Contributed by EARL HUGHES.

AMONG THE AMATEURS

Our Amateur Radio Station Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of stations unaccompanied by that of the owner. Dark photos preferred to light toned ones. We pay each month $3.00 prize for the best photo. Make your description brief. Address the **Editor.**

AMATEUR RADIO STATION CONTEST.

Monthly Prize, $3.00.

This month's prize winner.

WIRELESS STATION OF HARRY WEBER.

Sending condenser: Open rack type, consisting of 14 plates 16x18 inches connected series-parallel, with eight knife switches to vary capacity. Mounted in hardwood rack. Have completed oil-immersed condenser since photo was taken.

Rotary spark gap: Twelve discharging points on aluminum disc, driven by 1/10 H. P. Robbins & Meyer's motor, with Cutler-Hammer rheostat.

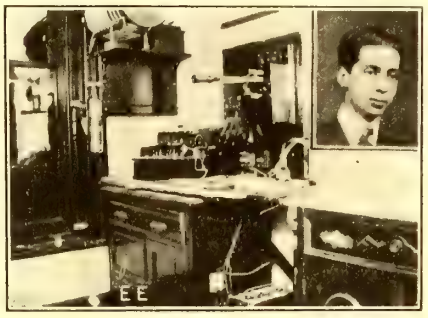
Oscillation transformer is composed of two spirals of heavy brass ribbon. Have Brandes hot-wire ammeter reading 0 — 5 amperes. I use anchor-gap and aerial switch that controls rotary gap; also have heavy wireless key. I get a reading of 4 amperes on hot-wire meter.

The aerial of my station is composed of four strands of 7-22 phosphor bronze cable, 70 feet high.

Transmitting set consists of 1 kw. commercial transformer, closed core, with six variations of power. Secondary voltage, 16,000.

Prize-winning Radio Station of Harry Weber.

The receiving set comprises: Loose coupler with primary and secondary tubes of Bakelite with six taps on primary and 10 on secondary. One variable can be thrown in series or shut in primary circuit; other variable in shunt with secondary. Cabinet is finished in black and is hand-rubbed and highly polished. Use storage battery to light audion filaments. I am getting good results with this set, and hear many amateurs within a radius of 500 miles. I can read a ¼-kw. set 300 miles distant and a ½-kw. set almost 800 miles away. Stations within 300 miles copy my signals strong, and I am heard at distances of 600 miles. I made all the instruments except the transformer. My call is 8 AM. Would like to arrange tests with any amateurs that hear me. Yours truly.



Canal Dover, O. HARRY WEBER.

BARRUTTE RADIO STATION.

The accompanying photograph shows part of my radio station which I desire to enter in your monthly prize contest.

The receiving set consists of a Marconi inductively tuned cabinet set. The tune can be changed from direct to inductive by a rocker switch. The detector is of the crystal type, and can be adjusted very quickly, and it is aided by a set of batteries and a potentiometer. The capacity used consists of a variable and fixed condenser. A loading coil and phones complete the set.

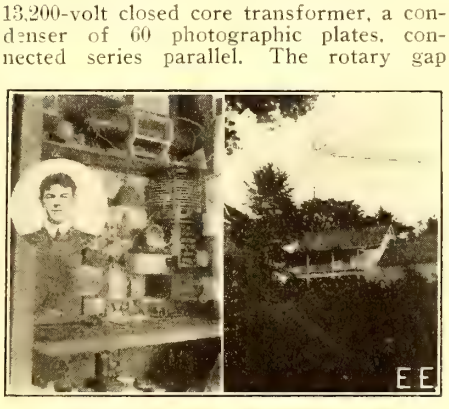
The set will respond to wave lengths of 15,000 meters. The sending apparatus consists of a 6-inch spark coil operated on 24 volts. The primary circuit is com-

Mr. Barrutte's Radio Outfit in Brooklyn, N. Y.

pleted by a navy type key, which is seen in front of the relay. The condensing unit consists of Murdock moulded condensers and a flanged air-cooled gap. The tuning is accomplished by an oscillation transformer. The antenna switches are shown on the switchboard. I have been picked up at New Canaan, Conn., by M. B. Porter, who has a large radio station there.

I can just about copy "NAM." My official call is 2PC.

L. BARRUTTE.



Brooklyn, N. Y.

STUART RADIO SET.

Below is a photo of my wireless station and electrical laboratory, the aerial and also a small one of myself.

My aerial, 108 feet long by 60 feet high, is composed of four strands of seven-strand copper wire spaced on 10-foot spreaders. It is grounded when not in use by a 100-amp. switch.

The transmitter consists of a ½-kw. 13,200-volt closed core transformer, a condenser of 60 photographic plates, connected series parallel. The rotary gap

Stuart Wireless Station and Aerial.

has 12 aluminum plugs and runs about 4,000 revolutions per minute. The oscillation transformer is of my own design and construction, and the wires are Nos. 6 and 8 aluminum, respectively.

The receiving set is of the cabinet type, and is complete by itself. It contains a 3,000-meter loose coupler wound with Nos. 24 and 32 wire, a loading coil, two fixed condensers, one rotary variable condenser, a Galena detector of the catwhisker type and a buzzer test. I also have a buzzer in the attic controlled by a push button within easy reach of my foot. My phones are 3,000-ohm Murdock type. I can hear NAA at noon with my phones several inches from my head. I have a license and my call letters are 1BG.

The large Tesla coil at the top of the picture was constructed similarly to one described in this paper a few months ago.

I have been a reader of the *Electrical Experimenter* for the past two years, and am pleased to see it growing in size and wish it came weekly instead of monthly.

H. CORCELL STUART.

St. Johnsbury, Vt.

RADIO STATION OF C. L. ROBINSON.

I give you herewith photo and description of my wireless station. Most of the apparatus are of Commercial make or made by myself. The outfit consists of the following instruments: One-inch Bulldog spark coil, one-pint Leyden jar, quenched and open spark gaps, key, aerial switch and five dry cells. Receiving outfit: Loose coupler of my own make, silicon detector, variable condenser made of two tin cans

C. L. Robinson and His Wireless Laboratory.

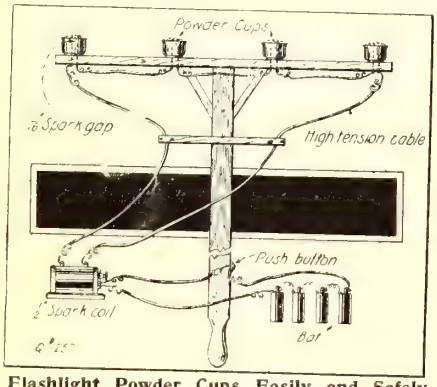
for use across L. C. secondary, one 1,000-ohm receiver, receiver shunt condenser and necessary switches. All the instruments are of my make except the spark coil, receiver and Leyden jar.

My aerial consists of four No. 12 galvanized iron wires 100 feet long, 20 feet high at one end and 25 at the other, with two lead-in wires from center, making a "T" aerial. The spreaders are 10 feet long. I have a brother living about one-quarter of a mile away and a neighbor who lives about one mile from one, both of whom have stations which I can hear fine. I also have a friend about four miles south of me who is putting up a station. I live in the Ozark Mountains in a valley, with hills on each side about 300 feet high, which accounts for me not being able to receive any great distance. I have tried grounding contact side of detector, which brings in signals considerably louder and some you can't hear at all without the ground. C. L. ROBINSON.

Laquey, Mo.

Submarines use electricity to propel them under water.

QUESTION BOX



This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

SPARK COILS FOR FLASHLIGHT IGNITION.

(257). D. A. Biggard, Frankford, Philadelphia, Pa., wishes to know about a spark coil for use in igniting photo flash-light powder?

A. 1. We would suggest a ¼" spark coil for your work, in igniting flash powder. You may use some No. 16 or 18, twisted lamp cord for connecting the battery, etc.

Flashlight Powder Cups Easily and Safely Ignited by Means of Spark Coil.

We believe you would find a ½" coil best if you intend to use several spark gaps in series, as your sketch indicates.

Diagram is given herewith showing how to connect up one of these coils for the 4 powder cups.

PLUNGER ELECTRO-MAGNET PULL FORMULA.

(258.) W. Le R. B., New York, has some solenoid or plunger electromagnets to build and wants to know how the strength of same can be computed?

A. 1. We give you herewith formula for calculating the pull in pounds for any length action of solenoid magnet on direct current; and you can thus readily compute the power of same.

The pull in lbs. of a D-C. solenoid is:—

$$P = A\,I\,N\left[\frac{I\,N}{l_1 c^2} + \frac{C}{l}\right], \text{ in lbs.}$$

In which: A is area core section in sq. in.; I is current in amperes; N the number of turns of wire; *la* the length of air-gap in inches; *l* the length of the coil inches, while *c* and C are constants. For soft iron cores at ordinary flux density, c=2660 and for *l* greater than 10 dia. coil; C=0.0096. For full details on this subject with design curves from actual magnets built, see Underhill's "Solenoids and Electromagnetic Windings," which we can supply at $2.25 postpaid.

WATCH DEMAGNETIZERS.

(259.) Berries & Co.,——; please give us full details on how to make a "Watch Demagnetizer" for direct current, 110 volts.

A. 1. Refer to the September, 1913, issue of this journal; worth five cents. Other numbers of *The Electrical Experimenter* can be supplied as follows: 1913 numbers, excepting May, June, July, or October; 1914 numbers, excepting January issue; price five cents straight, the copy, prepaid.

1-4 inch COIL CONDENSER.

(260.) Alan C. Rockwood, Iowa City, Iowa, states that his small ¼" spark coil sparks excessively at the vibrator and wants to know the remedy.

A. 1. This is most probably due to a breakdown of the primary condenser. A condenser suitable for this purpose may be composed of about 18 sheets of waxed paper, covered on both sides or interleaved with tin-foil sheets about 3 inches square; leaving ⅜ inch margin of paper around the tin-foil. Connect every other foil leaf to either side of the vibrator, alternately; i. e., 9 sheets to each side.

In regard to the small rheostat, would say that the voltage drop of same may be figured from the resistance which is 10 ohms and the current capacity which is 2 amperes at full load; or the volts drop equals Res. × Current, or 10×2=20 volts drop.

Want to Swap?

If you have anything to buy, sell or exchange and want to make sure of doing it quickly and at an insignificant cost advertise in the

Scientific Exchange Columns
OF
The Electrical Experimenter

You will find advertised in these columns:

Photographic supplies, Phonographs, Wireless Apparatus, Electrical goods, Bicycles, Motorcycles, Rifles, Gasoline Engines, Microscopes, Books, Skates, Typewriters, Etc.

The owners of these things wish to ***"swap"*** them for **something else, something which you may have.**

The Rates

One cent per word (name and address to be counted) minimum space 3 lines. Average 7 words agate to the line. *Remittance must accompany all orders.*

The Classified Columns of the ELECTRICAL EXPERIMENTER GET RESULTS

More than 30,000 Electrical Experimenters will see your ad.

LIGHT ACTION ON SELENIUM.

(261.) A. J. Hain, Lakewood, Ohio, inquires as to the action of light on selenium, partly covered over with an opaque shutter or screen, etc.

A. 1. Relative to the action of Selenium Crystals, etc., would advise that wherever the Selenium is covered over with some light-proof material, the Selenium at that point will become of very high resistance. Of course, a slight effect will probably be made on the Selenium so covered by reflection from the uncovered surface of same, as you intimate.

As a matter of fact, it has generally been found that the resistance of Selenium Cells varies pretty well in proportion to the amount of light thrown on same.

Selenium in stick form, chemically pure, may be purchased on the market. However, its resistance is infinitely high in the pure state. It has to be fused, crystallized and carefully annealed before its action is the same as in standard cells.

You will find considerable information on Selenium Cells and their construction in the August, 1914, *Electrical Experimenter.*

RADIO CIRCUIT PROTECTION.

(262.) Dayton D——, Limon, Colo., mentions the use of small fuses for protecting wireless sets from static aerial currents:

A. 1. Fuses are hardly ever used in protecting radio receiving apparatus from static or lightning discharges, and the common method of giving such protection is to connect an anchor spark gap about 1/100 of an inch long, across the aerial and ground wires where they join the receiving set. This system is used in the United States Navy, and also on most commercial installations.

There is no law stating definitely that you may not use a stationary spark gap, and these can be employed for short range wireless transmitters, where they do not send over the border line or interfere with the interchange of government or commercial radio messages over such State boundary line.

A. C. QUESTIONS.

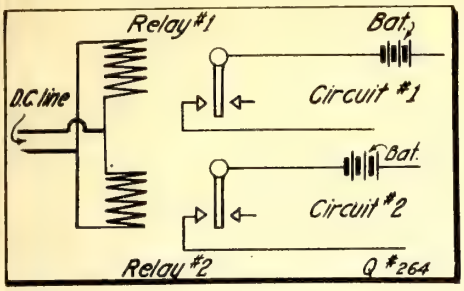
(263.) A. L. Franklin, Chickasha, Okla., asks several questions on A.C. motors, transformers, etc.:

A. 1. Twice the size of wire now used on the coils on your 60-cycle A.C. motor, should be employed for the new winding and consequently one-half the number of turns should be placed on same, for 120 cycles frequency. You may figure the circular mils area of any wire from the Brown & Sharp wire table given in most textbooks and catalogs.

It is probably best to connect two receivers with widely different resistances on multiple, but two high resistance receivers should be connected in series and the same holds true for a pair of similar type, low resistance receivers.

The wave length of loose couplers, is explained in detail in the September, 1914, issue of *The Electrical Experimenter.*

Any transformer will show a small consumption of current on watt-hour meter in the primary circuit; even though the secondary is open circuited. This small current consumed by any transformer as mentioned, is known as the magnetizing current.



POLARIZED RELAY PROBLEM.

(264) Walter J. P——, Grand Rapids, Mich., asks us about using 2 single polarized relays, etc., to signal when direct current is passed through the circuit in a positive or negative direction and vice versa. Relays to remain open when no current traverses control circuit.

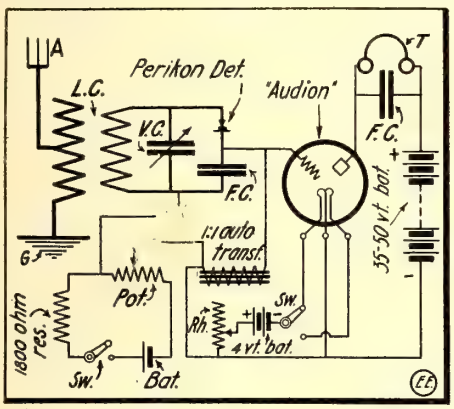
A. 1. Relative to the use of polarized relays, special circuits, etc., we may say, first, that you can employ a couple of the plain polarized relays hooked on to the circuit in parallel as shown in the diagram.

If you wish to have one relay of the dif-

ferentially wound type act to close a local circuit, when positive or negative current is passed through the coils of same, you will have to arrange the armature with balancing springs on either side; so that nor-

With no Current in D. C. Line, Polarized Relays 1 and 2 Remain Open. Positive or Negative Current Through D. C. Line Closes Respective Relay.

mally or with no current in the magnet coil circuits the armature will rest midway between the two platinum contact screws of the relay. About six to seven milli-amperes are required to operate these relays.



AMPLIFIER HOOK-UP.

(265) J. W. Halligan, New York City, asks us:

Q. 1. Is the diagram I show correct for using an Audion to amplify the wireless signals as received on a crystal detector, such as the Perikon?

A. 1. The diagram you show is not correct. We do not believe it would work at all. We give you below proper diagram showing how to arrange a single Audion bulb to amplify from a Perikon Detector, and it is claimed that this arrangement will yield as high as 20 amplification factor.

The diagram is quite plain and needs no lengthy explanation. The auto-transformer of 1-1 ratio shown should have about 9,000 ohms resistance and is very well composed

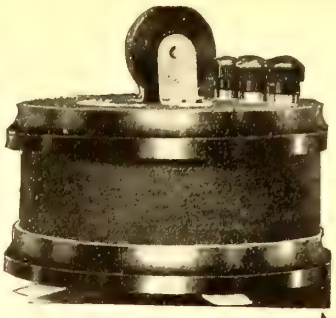
Audion Amplifying From Crystal Detector.

of three or four spark coil secondaries. These should be placed end to end with a common soft iron wire core passed through their center. A Perikon detector is suggested as best for the purpose, and the potentiometer shown is for adjusting the battery current applied to same.

D. C. DYNAMOS.

(266) Frank Moore, Kemp, Tex., wants advice on small D. C. dynamo building.

A. 1. On the matter of small dynamos and their windings, etc., we refer you to the excellent 25c. book by Marshall, which we supply, entitled, "Small Dynamos and Motors and How to Build Them."



We may say that in general, with a given size of armature, it is rarely possible that you can gain any great amount in output from the machine by increasing the field strength to any extent; providing, of course, the field is of sufficient strength in the first place, all things considered. This is due to the basic fact that the output in amperes of

HYPNOTISM!

Be a HYPNOTIST and MAKE FUN and MONEY!

It takes but a few hours to learn. The study is both easy and fascinating. Hypnotism is an endless source of fun and wonder. If you know how to Hypnotize you can perform some of the most marvelous feats imaginable. You can do a hundred amazing things that other people cannot do. You can surprise your friends and make yourself popular. You can place others under this strange and mystic spell. You can compel them to think, act and feel just as you wish. If you want to **make money** you can do so by giving entertainments, treating diseases or teaching the art to others. Why work for others, when you may master this money-making profession so easily? Investigate **NOW!** You may learn at your own home. I will send you my **free treatise** for the asking. It tells you about Hypnotism and how you may easily learn it. It is profusely illustrated and is written in a simple style easily understood by all. Anybody may learn from it of how the Hypnotic Spell sways the will of its subjects, heals the sick, reforms the degraded, overcomes bashfulness, helps to trade or position, amuses an audience for profit, and gains for the operator himself courage, will-power, and a means to health, wealth and happiness. It also treats fully on Personal Magnetism and kindred subjects. Remember, this treatise is **absolutely free.** Simply write for it, and it will be sent by next mail, all charges paid. Don't send any money or stamp, but send your name and address **today.** Address:

HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books
Price per $1 Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

"THAT'S JUST WHAT I NEED"

They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED

FREE EXAMINATION OFFER

the armature, and conjointly of the dynamos, depend upon the size of the armature conductor or wire. This is invariably figured for D. C. machines at 600 circular mils per ampere of armature current. You can thus readily figure the capacity of any armature from a common wire table as given in any text-book, catalogues, etc.

With an armature having two field poles and two brushes on the commutator, there is of course provided two divided paths through the armature for the current, and each half of the armature would thus carry one-half the total current; that is to say, that if the armature was to develop or handle a total current of 100 amperes, then each half of the armature winding would carry 50 amperes, or the armature winding would be designed to have a cross-sectional area of 50 times 600 circular mils.

TRANSCONTINENTAL TELEPHONY.

(267). A. L. Franklin, Chickasha, Okla., wishes to know the strength of current used in telephoning across the continent.

A. 1. We may say that 48 volts from a storage battery is the principal current used in sending speech from New York to San Francisco over the Bell system. However, this current works through an Audion type amplifier, and the secondary or wing circuit of the amplifier has about 100 to 110 volts battery current in same.

A. 2. In regard to the human body having a resistance of, say, 5,000 ohms or more, measured from hand to hand, and the effect of applying 50,000 volts through this circuit from a small induction coil, will say that as the coil could only deliver a small fraction of an ampere, you could not, of course, cause any greater current than a minute fraction of an ampere to flow. Shocks from spark coils are always very unpleasant, and in the case of some persons the discharge from a fairly large spark coil may indeed prove fatal.

RANGE OF RADIO STATIONS.

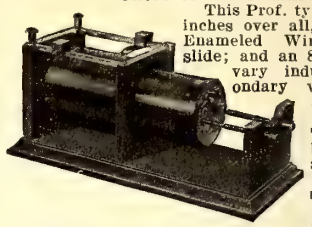
(268) Orval Shryock, Box No. 1, Brighton, Ia., asks about the range of radio stations.

A. 1. We do not quite understand your query as to how far a certain radio receiving station can operate over, but may say that it must have an aerial large enough and instruments of sufficient sensitivity to pick up so many micro-watts out of the ether or from the transmitted etheric wave.

To make this matter clearer, we will suppose that you have an ordinary amateur station located on the Atlantic coast of the United States. Now, suppose that you try to pick up the wireless signals from the Eiffel Tower. Undoubtedly, you will not be able to accomplish this unless you have a particularly large aerial, say 1,500 feet long, with the very best instruments, including some form of amplifier. However, we may remark that several commercial and private radio stations of the very highest character in design, etc., located around New York City, pick up the Eiffel Tower repeatedly, and also hear the German stations working regularly every day; whereas the small amateur stations cannot do this, as their instruments are not of sufficiently high sensitivity and efficiency, and also their aerials are entirely too small to pick up sufficient energy. About 30 to 40 micro-amperes in the receiving station aerial circuit will give good signals on a first grade set.

AERIAL ANTENNA CURRENT.

(269). Wm. Rogers, Ohio, Ill.



A. 1. The transmitting range of a wireless station depends in general upon the amount of watts expended in the antenna. In fact, it is given by the following for-

A Fortune to the Inventor

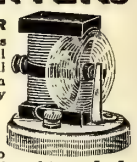
who reads and *heeds* it, is the possible worth of the book we send for 6 cents postage. Write us at once.
R. S. & A. B. LACEY, Dept. E, Washington, D. C.

INDUCTIVE TUNER

There Is None Like It.

This Prof. type Tuner, 7x7x15 inches over all, is wound with Enameled Wire, has double slide; and an 8-point switch to vary inductance of secondary winding. Price, $7.00.

Parts of this Tuner, unassembled; wood work stained, tubes wound, taps made, etc., $5.50. Our latest catalogue has 64 pages, and over 100 illustrations; and deals entirely with Wireless Telegraph Apparatus.



You should note our Rotary Spark Gaps. Also parts of same sold separately, if desired. Everything else equally interesting, especially prices. Send 5 cents in stamps for this large new catalogue B-B-24. Positively none sent otherwise.

F. B. Chambers & Co. 2046 Arch Street, Philadelphia, Pa.

EXPERIMENTERS

LITTLE GIANT MOTOR
is nearly 3 in. high. Runs at high speed on a single cell of battery. Very powerful and may be used to run small toys, etc. Just the motor every boy has been looking for.

Sent postpaid for only 50 cents

THE SIMPLEX TELEGRAPH

An opportunity for every boy to learn to telegraph and to put up a line with his chum. This is a full sized telegraph set consisting of a fine key and sounder mounted on a polished base. Will work any distance. An excellent Field Telegraph for Boy Scouts.

Sent postpaid for only $1.00.

This Is the Experimenter's Reference Book
EVERY BOY NEEDS IT

It's the latest edition of the famous **AMCO Catalog,** nearly 200 pages, fully illustrated. Complete description and prices of the latest Electrical and Experimental Apparatus—Storage Batteries, Rectifiers, Transformers, Induction Coils, Wireless Apparatus, Lamps, Flashlights, Meters, X-Rays, Books, Tools, Electric Railways, Steam Engines, Water Motors, Dynamos, Motors, Telegraphs, Telephones, Electrical Supplies, Model Aeroplanes and parts for building your own apparatus. A treatise on Wireless Telegraphy telling how to put up an aerial, connect apparatus, etc., together with a Call List and Wiring Diagrams. FREE with every catalog. 6c. in stamps will bring you this wonderful book.

The best catalog of wireless apparatus, etc., published.

"The Experimenter's Supply House"

ADAMS-MORGAN CO. Dept. E., Upper Montclair, N. J.

SEND FOR COPY OF OUR

New Wireless Manual No. 9

Its pages contain simple formulas for calculating the natural period of an antenna; capacity of a receiving or transmitting condenser; spark frequency of rotary spark gaps; tables for calculating the correct amount of wire for the construction of magnets and tuning coils; tables for ascertaining the spark lengths of different voltages; the Federal regulations regarding the restrictions of wave lengths for amateur stations; instructions for the installation, maintenance and operation of wireless stations; directions for learning the code, workable diagrams and a complete list of up-to-date wireless instruments and accessories, together with other features of interest to the amateur or professional wireless enthusiast.

Containing as it does a fund of valuable information not generally contained in a catalog it approaches nearer a text book in the fascinating field of wireless telegraphy.

It is printed on good stock with a heavy paper cover in two colors. No expense has been spared to make it accurate and reliable.

We make a charge of 10 cents for it which amount will be allowed on an order amounting to $1.00 or more.

Send for our Pocket Catalog W 28

It contains over 240 pages, with over 1,000 illustrations, describing in plain, clear language all about Bells, Push Buttons, Batteries, Telephone and Telegraph Material, Electric Toys, Burglar and Fire Alarm Contrivances, Electric Call Bells, Electric Alarm Clocks, Electrical Batteries, Motor Boat Horns, Electrically Heated Apparatus, Battery Connectors, Switches, Battery Gauges, Wireless Telegraph Instruments, Ignition Supplies, Etc.

It Means Money Saved to You to Have Our Manual and Our Catalog When You Want to Buy

MANHATTAN ELECTRICAL SUPPLY COMPANY

NEW YORK, 17 Park Place
CHICAGO, 114 So. 5th Ave. ST. LOUIS, 1106 Pine St.
SAN FRANCISCO, 604 Mission St.

mula, wherein I^2 is the current in the antenna as read on a hot wire ammeter; R O is the actual or ohmic resistance of the antenna circuit, and R D is the radiation resistance of the antenna circuit. This latter term, R D, is usually about four times the ohmic resistance. The watts radiated $= I^2 \times (RO + RD)$. As you will perceive, this expression really takes into consideration the watts in the circuit. About 10 watts to the mile may be figured on for small and medium size plain sparks gap type transmitters, with closed core transformers.

LONG DISTANCE RADIO RECEIVING.

(270) F. L. Peoples, Jacksonville, Fla., writes us about a receiving set for transatlantic service.

A. 1. With reference to reciving transatlantic messages, will say that undoubtedly for this work you will have to use a pretty large aerial, one having, say, a length of 1,000 to 1,500 feet and composed of a couple of strands of phosphor bronze cables.

This stretch of wires should be elevated 150 to 200 feet, and preferably more, above the ground, and the wires should be spaced about 20 feet apart and well insulated; also, in such an event you will have to use the very best phones possible, and undoubtedly some form of amplifier, unless your radio receiving set is particularly efficient.

LAMP BULB EXPERIMENT.

(271) Russell Baley, Hillsboro, Wis., states that he tried lighting an incandescent lamp bulb from the secondary terminal of a spark coil, and wants to know why the filament in the bulb was attracted to the glass.

A. 1. The effect you describe with regard to holding an ordinary 16 C. P. electric light bulb in your hand near a spark coil is a common one and familiar to all electrical experimenters. Most probably the reason why the filament in same is drawn toward the glass wall is due to the fact that the human body gathers an electric charge, and this is spread over the outside of the glass on the bulb. This charge, of course, tends to attract the charged filament inside the bulb by electro-static action.

A. C. TRANSFORMERS FOR TELEGRAPHY.

(272) D. A. Hoffman, Akron, O., inquires about using small A. C. step-down transformers for a short telegraph line instead of batteries.

A. 1. You may use step-down low-voltage transformers for the telegraph line you are interested in. You can use a ground return if desired, and if an accidental short circuit exists on the line very long it is liable, of course, to burn out the transformer windings. You should in this case place a very small fuse wire or link in the secondary circuit to protect against such short circuits. Regular fuse block and fuses should, of course, be placed in the primary transformer circuits of 110 volts, etc., as usual.

HOW TO TELL THE POSITIVE WIRE.

The electrolysis of water is a familiar example of the decomposing effect of the *direct* electric current. By the use of such a current water can be resolved into its component elements, hydrogen and oxygen. In order to do this the terminals of a direct electric current are inserted into a dish or glass containing the water. The positive terminal in known as the anode, and the negative as the cathode. When the current is turned on, it passes through the water from the positive to the negative terminal (from the anode to the cathode), and electrolyzes or decomposes the water. The most gas bubbles are given off at the negative electrode.

Money in Patents

Inventors, do not fail to protect your ideas. Fortunes are being realized from patents. Manufacturers are writing for patents secured through us. We place our clients in direct touch with these manufacturers and assist in selling your patent.

A "WIRELESS" MENU.

The members of the Institute of Radio Engineers recently gave a dinner at New York City in honor of Mr. R. H. Marriott, United States radio inspector, who had his headquarters in New York City, but who was transferred to Seattle, Wash. The following "wireless" menu was served, and Dr. Alfred N. Goldsmith acted as toastmaster in the absence of Dr. John Stone, president of the Institute:

(Note: We are enjoined from serving courses at a frequency exceeding 250 per second.)

Automatic Starter to Order.
Rat-tail of Non-adjustable Bare Bluepoints for Bivalve Detectors.
Gumbo Electrolyte in Insulating Container of fixed capacity.
Portable Submarine Equipment in Dielectric.
Brush Dischargers. Oval Insulators.
Sans-Filet of Bass.
Podker Ultraudion Detector, Spud Type.
(Licensed for Use in Dining-room only.)
Vol-au-Vent of Jiggers, with Spherical Electrodes.
Fancy Sleet, with Plain Aerial.
Etherized Chicken, on Switchboard with Protective Devices.
Cohered Low Temperature Cream, with Spade Electrodes.
High Powered Cheese.
Radiation from Tree Antennae.
Ungrounded Coffee.
(Note: Saturation point should not be exceeded. Avoid examining tikker.)

COOPER HEWITT MERCURY OSCILLATOR.

(Continued from page 21.)

alternating current of any frequency, says *Electrical World*. Altho the rectifier is now said to be in such form that it may be used as a radio receiver of sensitiveness considerably greater than that of the most delicate electrolytic detectors, since the incoming energy is not only rectified but amplified, it is the oscillator which Dr. Hewitt believes to be of the greater commercial importance, both in radio signaling and in the transmission of power. At the present time the technical and physical details of the apparatus cannot be disclosed.

During the experimental study of various peculiar phenomena which occasionally accompany the operation of the mercury-arc rectifier, Dr. Hewitt encountered nearly a year ago an entirely novel set of conditions. Close investigation of these developed the fact that under certain circumstances the relations between current, voltage and resistance in the vapor conductor were of a kind absolutely outside the limits of his previous experience. Research into these curious effects resulted in the new oscillator, which, Dr. Hewitt states, is dependent upon electrical principles quite different from any hitherto used.

Not only is the physical basis of the invention a departure from earlier work, but the results already achieved have not previously been obtained through any other instruments. Even in its laboratory form, the oscillator has been found capable of producing, from direct current, sustained alternating currents of any frequency up to 100,000 or more cycles per second. The efficiency of conversion is excellent, and the low internal losses of the apparatus indicate that commercial use in numerous ways will be entirely feasible. In contrast to oscillators which have heretofore been suggested, the device is inherently capable of handling large amounts of power.

A characteristic of the device is that the frequency of oscillation may be

varied instantaneously over a wide range of values, which feature should increase the importance of the oscillator in its application to radio transmission. Similarly, the output in power may be altered easily and quickly, and through this property Dr. Hewitt anticipates that the apparatus will find extended use as a generator for radio-telephony. The instrument appears to be extremely rugged and to a large extent, self-protective when subjected to potentials much above the normal values used in operating.

Several distinct modes of operation are possible for the oscillator, and at the present time exhaustive researches, including oscillographic studies, are being made into the complicated electrical actions in the circuits of the apparatus. The correlation of these data now being obtained with the results of earlier investigations into gas and vapor conduction phenomena, should assist in the rapid growth of the new oscillator into a commercial machine. Dr. Hewitt has expressed the belief that after a reasonable period of development, such as was required to bring the mercury rectifier to its present forms, the oscillator should find extended practical use in many fields besides that of radio signaling.

AMATEUR WIRELESS PLANTS CLOSED BY GOVERNMENT.

Reports from a number of readers located in the western part of the United States, including the Philippines, indicate that close restrictions are being enforced by Government radio authorities in charge, regarding the operation of amateur wireless stations. As the majority of these stations, or at least those possessing sufficient power to cause any trouble, are all registered under the radio law now in effect, it does not seem fair to shut down every amateur radio station indiscriminately.

The radio amateur is entitled to as much attention as anyone else, and besides he is sworn to an oath of secrecy if he possesses a Government radio license.

We give below a letter from Mr. Walter Maynes, of San Francisco, which explains what we are driving at in part:

"In the Sixth Radio District, which embraces California, Utah, Nevada, Arizona and Hawaii, the radio amateurs have been refused permission to either send or receive ever since the war in Europe began. Rear Admiral Pond, of the Twelfth United States Naval Inspection Department, placed the ban on the wireless amateurs, much to their regret. The Sunset Radio Association, San Francisco, of which Walter Maynes, a licensed operator, is president, has taken the matter up, and is circulating petitions throughout the entire Sixth district for signatures of amateur operators, the intention being to present these petitions to Admiral Pond and induce him to lift the ban.

"The amateurs pledge themselves to a strict observance of the nation's neutrality, and hope to be placed on their honor, in the matter of sending and receiving. All operators in this district are eagerly availing themselves of the opportunity to sign the petitions and thus boost the good work. These petitions may be secured by addressing either Walter Maynes, president, 207 Hugo street, San Francisco; Carroll Reed, secretary, 1683 Seventh avenue, San Francisco, or Howard Lee, 1580 Grove street, San Francisco."

Flash-light batteries usually consists of two or more cells in series. Thus a three-cell battery gives 4½ volts; a four-cell battery, 6 volts, etc.

PORCELAIN

"THAT'S OUR BUSINESS"

Standard and Special Shapes, Regardless of How Difficult

We illustrate one hard shape we make. A pair of rolls 7½" long and 1" in diameter with 8 holes on ends and middle. They must be perfectly straight and we make them so. It's hard but not for us. We can make your difficult designs also. Send us blue print for quotations.

Another New and Improved Tool of Millers Falls Make

Here is a new hand drill designed to do a better job in quicker time with less effort and less trouble and fulfilling each purpose perfectly.

MILLERS FALLS
HAND DRILL No. 306

It is provided with a simple and effective ratchet, located on the crank handle, which is of great convenience when working in cramped corners or on a delicate job. The handle is detachable and hollowed for holding twist drills up to the largest size within the capacity of the chuck. The chuck is of the famous STAR three jaw pattern closing evenly on, and centering accurately, round shanks from 0 to ¼ inch in diameter. Jaw springs are protected from injury.

Solid steel frame. Cut gears with a small steel working gear and steel idler gear to equalize bearings, both encased and rendered dirt-and-dust-proof. Choice hardwood stained handle, all metal parts handsomely nickeled with exception of large gear.

The splendid quality of material and workmanship in this drill is typical of all tools of Millers Falls Make. Ask your dealer to show you Hand Drill 306 and also Millers Falls Bit Brace 732, Automatic Borer 8 and Hack Saw Gauge 53, new tools that include new features to make work easier.

Send for pocket catalog showing complete line.

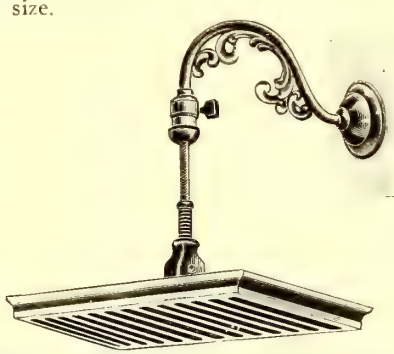
BATTERY TYPE ELECTRIC CEILING LAMP.



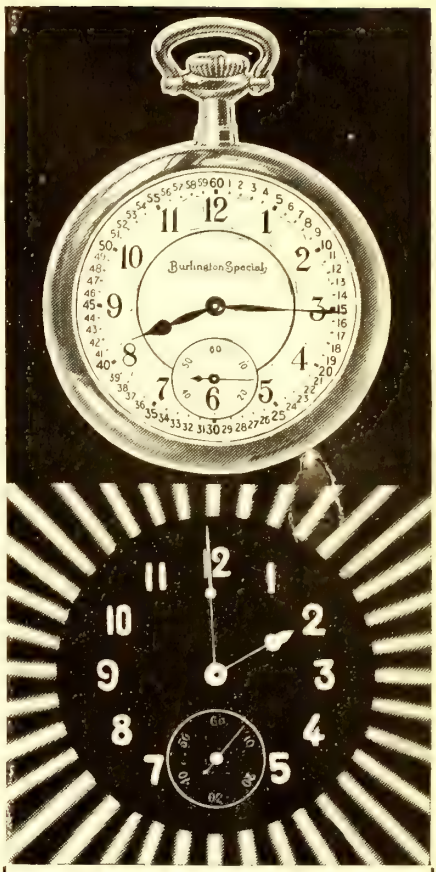
The accompanying illustration shows a unique battery-operated lamp which can be attached to the ceiling of a porch, closet or pantry or fastened to the wall. It is provided with a long string which is connected to the switch. The lamp will burn continuously on one ordinary dry cell for about forty hours, or, if used intermittently, from six to twelve months. The device is equipped with a tungsten lamp and a large reflector and lens. The case is waterproof and fireproof and carries handy attachment hooks. New batteries are easily replaced in same when necessary.

A PORTABLE ELECTRIC AIR HEATER.

A recent innovation is a portable electrical air heater. It operates on the electric light current of 100 to 220 volts. Attaches to any socket like a lamp, and no special wiring is necessary.

It gives intense heat and takes the chill out of rooms in a very short time, the makers claim. It is cheaper to operate than any other electric air-heating device, and by its special construction it gives nearly twice as much heat as any other heater of its size.

Electric Heater to be Used in Any Lamp Socket.



It is very convenient for traveling, being light and compact. It is made substantially throughout of pressed steel, heavily nickel plated and highly polished. The heating element is non-corrosive and non-oxidizable. It will stand intense heat without deterioration and is not affected by repeated heating or cooling. A special reflector intensifies the heat and deflects it downward. It is made by the Lindstrom-Smith Co., of Chicago, Ill.

BOOK REVIEW.

American Handbook for Electrical Engineers. Harold Pender, editor-in-chief., Prof. of Elec. Eng., University of Pennsylvania, formerly Director of Electrical Research, Mass. Inst. of Tech. Full morocco covers. 2050 pages, 7x4¼ inches. Gilt edged. Thoroughly illustrated. Price, $5.00 net. John Wiley & Sons, New York.

The book is a compilation of 260 articles upon the various branches of electrical engineering and allied engineering topics. The articles are arranged alphabetically with copious cross references. In addition, a detailed index occupying 60 pages is given at the end of the volume. The 26 authors of the articles are leaders in the engineering profession, and are well qualified to write upon their respective topics.

The articles cover the following sub-

A useful gift. A necessity for dining room, bedroom, bathroom, kitchen.

LAVA HEATER
Patented, Trade Mark Reg.

FREE ADVICE given by experts in regard to any electrical, mechanical or other technical books. So many books are published about each subject, it is difficult for most persons to know which is the best book for his particular purpose.

Electrical, Mechanical and Other Technical Books for home study or for reference. In return for this free service we ask that after you have decided what book you want, you will order it from us. Our price will be as low as you can buy it elsewhere.
Send for details of our plan and state which subject you are interested in.
Technical Service Bureau, 51 E. 42d St., New York

jects: Mathematics; Units and Conversion factors; Engineering Materials; Electric Measuring Apparatus; Primary and Secondary Batteries; Dynamo Electric Machinery and Transformers; Power Stations; Transmission and Distribution of Electric Energy; Electric Traction and Railroad Engineering; Electric Lighting and Illuminating Engineering; Industrial Applications of Electricity; Electrochemistry; Telephony and Telegraphy; Elements of Mechanical and Structural Engineering; Elements of Steam and Heat Engineering; Elements of Hydraulic Engineering.

Altho such a handbook must necessarily contain information in a condensed form, it has been the endeavor of the editorial staff to make each article sufficiently complete to render the information contained therein of greatest practical value to those interested in installing, testing, designing and operating of electrical equipment and allied lines.

Considerable space is devoted to those mechanical and civil engineering subjects which are closely related to electrical engineering practice. This gives the engineer his more frequently needed data within the covers of a single book, and saves the student or young engineer the expense of buying handbooks on other engineering subjects. An allied subject of especial importance is the application of motors in all branches of modern industry.

The wireless section by Prof. G. W. Pierce is thoroughly up-to-date and contains all the leading formulae used in designing and testing radio equipment. In fact, it is the best condensed and practical data the reviewer has yet run across in any engineering book.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC.,

Required by the Act of August 24, 1912, of THE ELECTRICAL EXPERIMENTER, published Monthly at New York, N. Y., for April 1, 1915:

ELECTRIC POWER FOR THE FARM

No gasoline to buy; no fire risk; no engine to get out of order; always ready; two-year guarantee; patented. Every farmer can afford it. Six hours' work of the horse makes electric light for a week or more. Write for prices and circulars. Farmer agents and dealers wanted everywhere.

The Electric Horsepowers Co., Mfgrs.
908 Elm Street Cincinnati, Ohio

Opportunity Exchange

YOU will probably find more opportunities and real bargains in these columns than anywhere else in the country. Most good things in life are hard to find and worth going after—these little ads illustrate that point; you alone will be the real loser if you don't take the time to scan through these columns.

Advertisements in this section 4c. a word for each insertion. Count 7 words per line.

Name and address must be included at the above rate. Cash should accompany all classified advertisements unless placed by an accredited advertising agency.

Ten per cent. discount for 6 issues, 20 per cent. discount for 12 issues from above rate. Objectionable or misleading advertisements not accepted.

Advertisements for the June issue should reach us not later than May 10th.

EXPERIMENTER PUBLISHING CO., INC., 233 Fulton Street, New York, N. Y.

* * * * * * * * * * * * *

Brooklyn, N. Y., April 15, 1915.

Gentlemen—The results obtained from my advertisement in the "Electrical Experimenter" really surprised me; in fact the demand for a certain instrument of mine exceeds the capacity for manufacturing and it is all through the "E. E." To date, 79 inquiries 12 orders. Might state last week filled a $50.00 *order netting me a profit of* $18.75. *As to the exact value of my orders to date, I prefer not to give figures; however, you will always see my ad. month in and month out. I can truthfully say that the "E. E." has it on them all, viz., for quick results, interesting reading matter, etc. Very truly yours,*

HARRY Y. HIGGS.

* * * * * * * * * * * * *

Practical Courses of Study

ELECTRICAL ENGINEERING

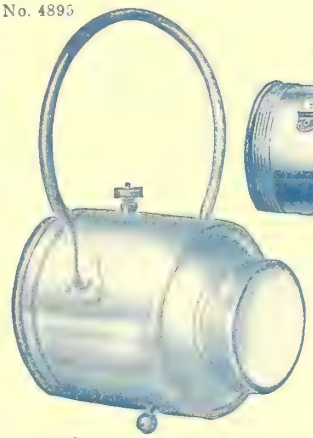
The men who get the **big jobs** are the men who understand the **principles** of electricity and their application.

Our Electrical Course teaches in plain, simple language and with easy lessons how to install and operate electrical machinery and appliances.

These lessons in Practical Electricity cover both Direct and Alternating Currents, high potential and high frequency currents, and all that is necessary to become a proficient electrical engineer.

The Course completely covers the field of practical electricity, including power-plant work, and the following subjects, viz.: Practical Electricity, Alternating Currents Simplified, The Electric Motor, Electric Wiring and Practical Mathematics.

FREE Ten text-books, handsomely bound, printed in large, clear type on fine quality of paper and profusely illustrated, are furnished **free** with this course.



The instruction is made so clear that any one can understand it, even though he has but a limited education.

The success of this school is due to the fact that we give the student only what he should know in order to become competent, and we do not waste his time and effort on useless matter.

With the Editor

WE believe that you will like this number of *The Electrical Experimenter*. As will be noted, the size has been increased again, from 32 to 48 pages, a 50% increase of text matter. No expense has been spared toward making this issue as perfect as we know how and you will agree with us that it is a big improvement over former numbers.

You will find feature articles in the June number which you cannot find in any other magazine. Our readers have come to know *The Electrical Experimenter* for publishing new and important things electrical, ahead of any other magazine, and we believe that you will agree with us that the manner in which we present the various articles now cannot be much improved upon.

Unquestionably this magazine to-day is the greatest electrical 10c. worth in the country; its 48 large pages represent 96 pages of the ordinary magazine size. The June number with its 123 illustrations and its 109 articles, excels a great many 15c. publications.

Nevertheless, we are far from satisfied; it is our ambition to regularly publish a magazine above 100 pages at 10c. a copy. Will you help us in our task?

First, we must satisfy you by knowing just what you would like us to publish. Our voting blank, which we print elsewhere, helps you to decide quickly; we urge you strongly to use it, as it will be an important factor toward making the magazine after your own heart.

Second, if you like this magazine tell your friends about it, or, still better, when you send in the voting blank, write the names of a few friends interested in electricity on the reverse side. We will promptly send them sample copies with our compliments.

The July issue will have some very important articles and you will also find in it some new intensely interesting departments which we know you will welcome.

Beginning with the August issue we have a nice surprise awaiting you; WATCH FOR IT!

Last, but not least, remember that the advertisers of this magazine make it possible for us to publish *The Electrical Experimenter*. Without their support we could never increase the size nor give you the articles as we do now. Considering this, the advertiser has a right to expect your patronage; he deserves the same consideration as the publishers; as a matter of fact, more so. For this reason you should send for the advertisers' literature, catalogs, etc., and you will find that it pays you to do so. Many of the catalogs and circulars advertised contain valuable information, not usually found in text-books. If you are interested in this magazine, you cannot possibly fail to be interested in our advertisers' literature as well as their products. THE PUBLISHERS.

WIRELESS BLUE BOOK

Who's Calling? You always know if you have a Wireless Blue Book on hand. Has alphabetically arranged list of all call letters of U. S. and American Wireless Telegraph Stations, Merchant Vessels, Vessels of the U. S. Navy, Revenue Cutters and Licensed and Unlicensed Amateur Stations and their location corrected to August 1, 1914. The most complete book of its kind ever published and one you cannot afford to be without. Size 6x8 inches, paper bound, with map of United States showing all principal radio stations, both government and commercial. Sent prepaid on receipt of 15c. Send now so that you can tell who is calling and being called.

HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books $1 Price per Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

"THAT'S JUST WHAT I NEED"

They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED

FREE EXAMINATION OFFER

Theo. Audel & Co., 72 5th Ave., New York

Please submit me for examination HAWKINS ELECTRICAL GUIDES (Price $1 each.)

Ship at once, prepaid the 6 numbers; if satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

Practical Courses of Study

ELECTRICAL ENGINEERING

The men who get the **big jobs** are the men who understand the **principles** of electricity and their application.

Our Electrical Course teaches in plain, simple language and with easy lessons how to install and operate electrical machinery and appliances.

These lessons in Practical Electricity cover both Direct and Alternating Currents, high potential and high frequency currents, and all that is necessary to become a proficient electrical engineer.

The Course completely covers the field of practical electricity, including power-plant work, and the following subjects, viz.: Practical Electricity, Alternating Currents Simplified, The Electric Motor, Electric Wiring and Practical Mathematics.

FREE Ten text-books, handsomely bound, printed in large, clear type on fine quality of paper and profusely illustrated, are furnished **free** with this course.

The instruction is made so clear that any one can understand it, even though he has but a limited education.

The success of this school is due to the fact that we give the student only what he should know in order to become competent, and we do not waste his time and effort on useless matter.

THE PRICE IS LOW AND THE TERMS ARE EASY

Another New and Improved Tool of Millers Falls Make

Here is a new hand drill designed to do a better job in quicker time with less effort and less trouble and fulfilling each purpose perfectly.

MILLERS FALLS

HAND DRILL No. 306

It is provided with a simple and effective ratchet, located on the crank handle, which is of great convenience when working in cramped corners or on a delicate job. The handle is detachable and hollowed for holding twist drills up to the largest size within the capacity of the chuck. The chuck is of the famous STAR three jaw pattern closing evenly on, and centering accurately, round shanks from 0 to ¼ inch in diameter. Jaw springs are protected from injury.

Solid steel frame. Cut gears with a small steel working gear and steel idler gear to equalize bearings, both encased and rendered dirt-and-dust-proof. Choice hardwood stained handle, all metal parts handsomely nickeled with exception of large gear.

The splendid quality of material and workmanship in this drill is typical of all tools of Millers Falls Make. Ask your dealer to show you Hand Drill 306 and also Millers Falls Bit Brace 732, Automatic Borer 8 and Hack Saw Gauge 53, new tools that include new features to make work easier.

Send for pocket catalog showing complete line.

Vol. III. Whole No. 26 JUNE, 1915 Number 2

Talking Motion Pictures and Selenium

By Samuel Wein

IN the present-day talking motion picture systems, use is made of simultaneously recording and reproducing animated objects and sounds, by means of combining the motion picture machine and the phonograph. The success attained thereby is of very little practical importance, owing to the difficulty of ensuring perfect synchronism. Another method recently patented was to record the sound waves from the needle of the phonographic "sound box" on the same film with the motion pictures; the success attained in this method is of no value at all on account of the fact that duplicates were impossible to make and not only that, but that the film in order to reproduce the sounds therefrom must be a little thicker than what it is; otherwise the sounds will not be reproduced successfully.

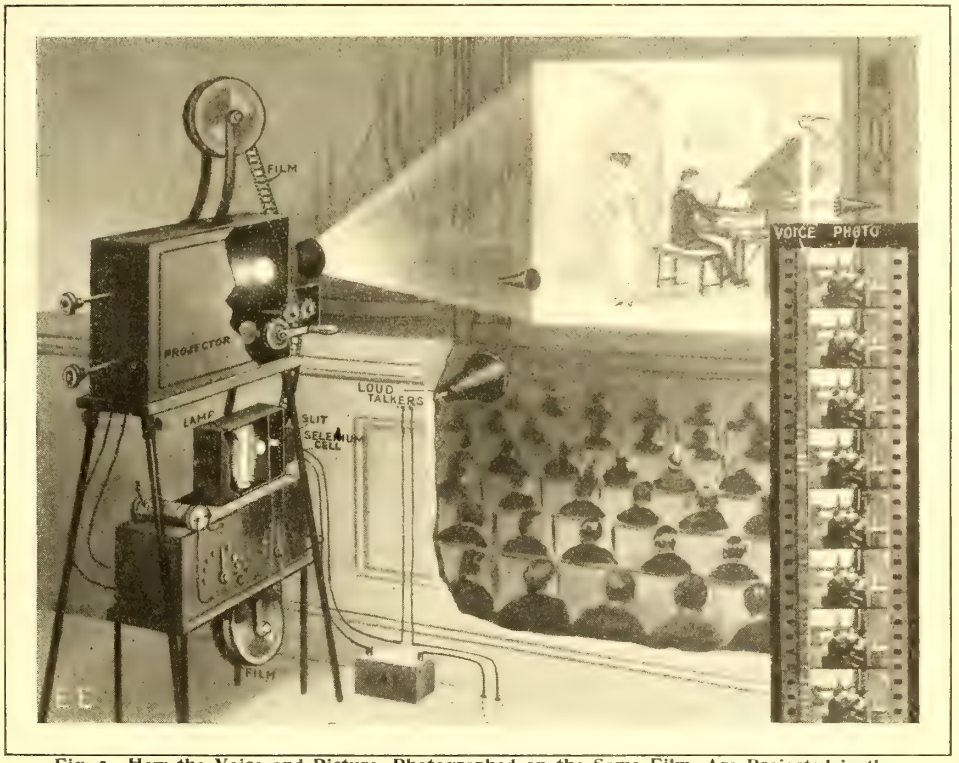

Fig. 2. How the Voice and Picture, Photographed on the Same Film, Are Projected in the Theater. At Right: Strip of Double Record Film.

It is essential to the correct reproduction of the movements of the persons or objects in combination with the sound waves, that the simultaneous movements and sounds should be recorded and reproduced simultaneously in exact synchronism and that the sound waves which constitute the sounds should not suffer any variation in the process of recording and reproduction, but should be recorded and reproduced without the introduction or accompaniment of any other sound waves.

It is obvious, therefore, that no true record or reproduction of the sound waves could be made by any mechanical process or means in which a hard substance necessary to make the impression comes in contact with another hard substance, such for instance as the recording or reproducing pin of the phonograph, because the friction caused between the two hard substances itself creates vibration or sound waves which accompany, vary or modify, the sound waves which it is desired to record and reproduce. These are recorded and reproduced with the latter, proving detrimental to their true acoustic reproduction. The record, therefore, must be taken or produced without any contact between the medium caused to vibrate by the sound waves and the record or recording substance. It is further obvious that if the impressions of the movements and sounds were recorded separately on separate records, the movements and sounds would be liable to vary in point of time and fail to synchronize with each other.

Another disadvantage of the present day talking motion picture machines or systems is that if the operator either neglectfully or wilfully tears or cuts out a piece of the film which constitutes the movements or actions, the result would be that a certain amount of action or movement is missing, but, the equivalent in sounds would still be in the phonographic record, thus showing the device would soon be put out of synchronism at this point.

In order to avoid this and to insure correct synchronism the late Dr. Ernest Ruhmer of Germany (see *Scientific American*, July 20, 1901) already in 1901, in his experiments with the "photographophone," was the first to suggest that the "movements and sounds must be recorded (photographically) simultaneously, on the same photographic film."

For the purpose of collecting or receiving the sound waves, a sensitive telephone transmitter is employed to transmit the sound waves electrically (in the usual manner) from the place where the sounds originate to the motion picture camera; which has a source of light so arranged that it will vary in degrees as to area, quantity, intensity and corresponding effect of light and shade, proportioned to their period and amplitude, simultaneously with the recording photographically of the successive movements of the objects on the same film, as outlined in Fig. 1. Fig. 2 shows voice waves thus photographed on the strip of film alongside of the picture space.

When such a film record is obtained, it is reproduced by causing light to pass through that portion of the film contain-

THE ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is 50 cents a year in U. S. and possessions. Canada and foreign countries, 75 cents a year. U. S. coin as well as U. S. stamps accepted (no foreign coin or stamps). Single copies, 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of **THE EXPERIMENTER PUBLISHING CO., INC.** If you change your address notify us promptly, in order that copies are not miscarried or lost.

All communications and contributions to this journal should be addressed to: Editor, **THE ELECTRICAL EXPERIMENTER**, 233 Fulton Street, New York. Unaccepted contributions cannot be returned unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

THE ELECTRICAL EXPERIMENTER. Monthly. Entered as second-class matter at the New York Post Office, March 1, 1915, under Act of Congress of March 3, 1879. Title registered U. S. Patent Office. Copyright, 1915, by E. P. Co., Inc., New York. **The contents of this magazine are copyrighted and must not be reproduced without giving full credit to the publication.**

ing the picture record of the successive movements, and so project them on to a screen, and also simultaneously cause light to pass through that portion of the film,

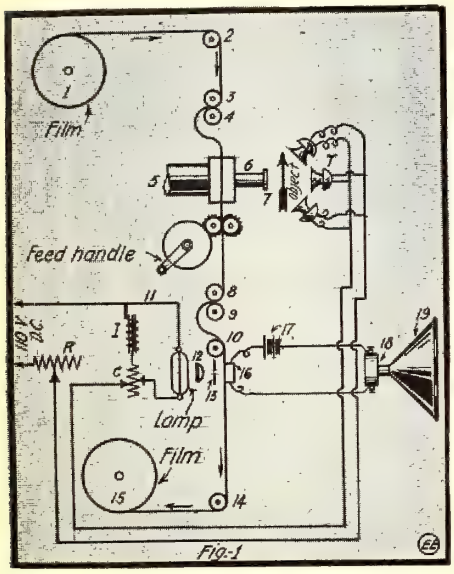

Fig. 1. Schematic Layout of Talking Picture Arrangement.

containing the *photographic sound record,* and thence onto a selenium cell, which is connected in series with a battery and a loud speaking telephone receiver.

In the diagram of this whole arrangement, fig. 1, the film unwinds down through the lense barrel and intermittent feed mechanism 5, 6, 7, idlers 3, 4, 8 etc., and also through the sound registering parts 11, 12, 13 etc. When the moving subject is photographed before the lense 7, the accompanying sounds as voices, music, et cetera, are picked up by a battery of microphones "T," and transmitted electrically over the circuit to a lamp circuit 11. This lamp is a straight filament "Radox" or "Line-o-lite" bulb, subject to voice control by the microphone "T" variations in resistance; R is a resistance, I an inductance and C a choke coil.

Every changing sound causes the microphones T, to affect the brilliancy of the "Radox" lamp. These light variations representing the voice are photographed through a small slit in a screen 13 on to the moving film. The film must pass steadily by this slit and not with an intermittent

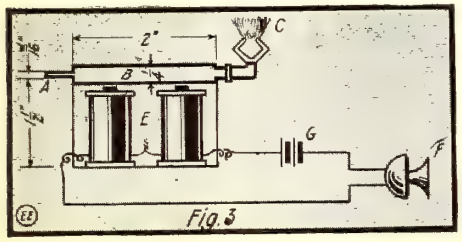

Fig. 3. Showing How the Voice Can Control Gas Flame.

motion, suitable propelling devices being used, of course.

After the sound is recorded the film is developed, fixed, and a print is made in the usual manner. It is then placed in a projecting machine with a selenium cell placed as shown at 16, connected in series with a source of current 17, and a loud speaking telephone receiver 18. The steady light from a lamp is thrown against the film through slit 13, and the voice wave bands of light and dark tones cause varying degrees of light to reach the selenium cell 16. Hence the cell has a constantly changing resistance, which is electrically communicated to the loud talkers 18, placed around the theater.

This loud-speaking telephone receiver is built on a new principle employing compressed air.

The usual method of recording photographically the voice on a moving film or plate is by means of a manometric capsule flame. This is arranged as per fig. 3, where an acetylene gas column in chamber B, is caused to vibrate by the varying electric current passing through the magnet coils E, controlled by a microphone F and battery G. This system has considerable promise for the future and opens up a wonderful field for experimenters.

For the last month radio amateurs and experimenters about New York have been greatly puzzled when listening to the powerful signals flashed off and on, the pitch of them being quite out of the ordinary. These signals are transmitted by the new Marconi Wireless Telephone at Wanamaker's, New York.

THE EDISON LABORATORY AND THE BRAINS BEHIND IT.

One can hardly imagine the great variety of wonderful inventions that have been developed in this small red brick building partly covered with creeping ivy. Thomas A. Edison, "prince of wizards," has spent many years and fabulous sums of money in perfecting his hundreds of inventions, some of which are more or less familiar to all of us.

The photograph herewith shows a recent likeness of Mr. Edison and his large laboratory situated at West Orange, N. J. Behind the large front windows is the wonderful library. It is in this library where Mr. Edison is encircled by thousands of books of every conceivable nature when looking up data for experiments.

Various departments are distributed throughout the laboratory building, such as the chemical department, where thousands of chemical reactions are critically studied; also the electrical, mechanical and research departments. It is in the latter department where Mr. Edison himself keeps continually busy. Every facility is afforded for thorough research in any branch of electrical engineering, and a staff of technical

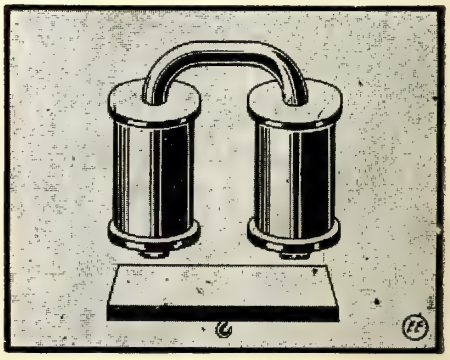
"Prince of Electrical Wizards," Thomas A. Edison.

Below: The Wonderful Edison Laboratory at East Orange, N. J.

experts are kept busy at all times, delving into the never-ceasing wonders of Dame Nature's secrets, under the guidance of the master mind.

THE ELECTRO MAGNET, PAST AND PRESENT.

It is now 95 years since the discovery of the magnetic field which surrounds a



Modern Type Electro-Magnet Lifting Pig Iron from Freight Car.

conductor carrying an electric current. This was discovered in 1820 by Oersted, of Copenhagen, Denmark. We are herewith presenting an illustration of the first small electro-magnet, which was made by Faraday. Such electro-magnets were difficult to make, of course, in the early days, as the copper wire had to be insulated by hand or else specially made up in a hand spinning device. The other photograph shows the latest lifting magnet which is widely used by large iron foundries for transporting pig iron from one place to another, unloading freight cars and the like.

Powerful electro-magnets are often utilized in lifting submerged iron bodies, such as parts of machinery, barrels of nails, etc., lost in steamer wrecks.

The present electric lighting system depends entirely upon the electro-magnets in the electro-dynamic machine, driven, of course, by a prime mover, such as a steam engine, etc. Practically the entire elec-

Early Type of Electro-Magnet Such as Used by Faraday.

trical industry is based upon Oersted's epoch-making discovery.

One should always speak of the electromotive-force (E. M. F.) between two points; never of the E. M. F. in a circuit, except when one is speaking of an induced E. M. F. or voltage.

The Rôle of Electricity in Film Plays

By H. Winfield Secor

PHOTO-PLAYS of modern vintage are at last realizing the wonderful possibilities of scientific accomplishments, such as "wireless," in making their stories of more than ordinary or passing interest. Notably are these scientific facts utilized in weaving the story and portrayal of Pathé Brothers' *The Exploits of Elaine* and the Universal feature film play, *The Black Box*. These films are perhaps more highly scientific in a popular way than anything produced heretofore.

That thousands of dollars should have been invested in producing them brings to mind the trite old adage that "truth is stranger than fiction." This has been proven so time and again, but never more forcibly perhaps than in the film stories that we are now favored with, particularly those above mentioned.

We show herewith several illustrations of the more interesting critical moments from these two film masterpieces. At Fig. 1 is seen one of the greatest electrical devices ever perfected in use. It is the "electrical resuscitator," invented by Dr. Le Duc, of the Nantes Ecole de Medicine, France, and which machine actually brought a girl back to life recently out on the Pacific Coast after physicians had said that she had been dead for half an hour. Arnold Daly, "the scientific detective," is shown manipulating the switchboard, while the patient is "Elaine" in the person of Miss Pearl White.

In the photo at Fig. 2 the "scientific detective" is again seen (wearing a beard), and here the marvelous Poulsen telegraphone, the electrical instrument that records speech on a tiny moving steel wire, is being connected to the rear of a telephone switchboard. The detective and his assistant then leave the telegraphone installed for a few hours, the telephone conversation between the conspirators meanwhile being faithfully recorded by the instrument. Afterward the instrument and its important message are removed and in his laboratory "Craig Kennedy" reproduces the voice record and at once gleans the conspirators' intentions.

Many more wonderful electrical devices are incorporated in *The Exploits of Elaine*. One of these little known devices is the selenium cell, which changes its electrical resistance when exposed to light. The strip of film reproduced at Fig. 2A shows the well-known E. I. Co. selenium cell with polarized relay, bell and battery used in the Pathé feature film. The flash of a pistol in the conspirator's house lowers the resistance of the selenium cell on the lapel of "Craig Kennedy's" coat, and transmits its signal over a wire passing through a window to the police who are waiting to raid the conspirators.

Turning to the newer film release called *The Black Box*, it may be said that here many of the scientific possibilities not just yet perfected for our every-day use are portrayed in the mysterious tale it depicts so perfectly on the screen. At Fig. 3 the leading characters are observed receiving a wireless message by the ever-changing short and long sparks on the front of the switchboard. Of course, this is somewhat fantastic, as wireless signals are extremely small currents and invariably interpreted through the medium of a set of sensitive telephone receivers. However, to lend more charm and life to the film story, the sparks "coming in" are undoubtedly much more efficacious in their effect on the lay audience.

The important moment depicted in Fig. 4 embodies the ultra-scientific achievement of "seeing over a wire" as yet to be perfected, but which has experimentally been verified on a small scale by Herr Ruhmer, of Germany, and others. The picture materialized or reproduced from a distance over an electrical wire appears on the rapidly rotating disc, seen on the front of the switchboard at the left of the photograph.

Truly, the "movies" are becoming more educational every day.

Fig. 2A.
Above: The Selenium Cell Outfit in "Exploits of Elaine" Film.
The Latest Film Plays Are Using Extensively, Applied Scientific Apparatus and Methods.

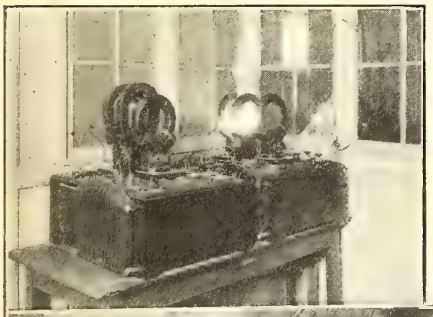
Fig. 1. Shows Miss Pearl White in "Exploits of Elaine," Being Resuscitated by Electricity. Fig. 2. The Telegraphone in Use. Fig. 3. Receiving Wireless Messages by Code "Sparks," and Fig. 4. Seeing by Wire or the Telephot."

THE ATOM.

Sir William Crookes recently said, "We are on the brink of striking developments in our knowledge of the structure of the elusive atom." An expressive phrase is the "elusive atom," for every attempt to discover it has been to chase it further into the darkness. When Sir William says "on the brink" he means that point in the chase where mechanical means have done their best and material definitions no longer apply. Just over that brink is something besides matter. It is force or spirit, and all one can know of it is its testimony in terms of light, heat or electricity.

It has long been suspected that matter is a mode of motion, and now the elusive atom will be called upon to substantiate it. That is the purpose of science today. Suppose it succeeds and this whole universe is only an expression of power, what affect is that going to have upon our philosophy, our theology and human destiny itself? If man is only a little bunch of electricity, what is going to become of that electricity when he is no more? Since force is indestructible it is a very interesting question.

A 50-watt tungsten lamp costs one-half cent per hour to burn, with current cost of 10 cents a kilowatt-hour.



NOVEL A. C. FAN MOTOR.

A new alternating current fan has made its appearance in which variation of speed is obtained not by means of a rheostat, but by rotating the windings of the fan. The advantage of this is that the fan may be started at any position of the winding without danger of burning out by merely operating a push button. The energy that is consumed by the fan varies with its speed. When this fan is operating at full speed it takes 24 watts, and at the lower speed it consumes about 7 watts.

One mechanical horsepower (H. P.) is equal to 33,000 foot pounds.

The Work of the Electrical Testing Laboratories

The rapid development of the electrical industry has made necessary the solving of a great many electrical problems. To meet this condition a corporation has been formed in New York State for the purpose of making electrical tests and solving electrical problems. With the growth of the industry these activities have expanded until at the present time the Electrical Testing Laboratories, Inc., is completely equipped and has assembled a staff thoroughly experienced in electrical, photometrical and physical tests. The following photographs indicate some of the work carried on at the Laboratories.

Left: Fig. 2. Vreeland High Frequency Mercury Arc Generators.

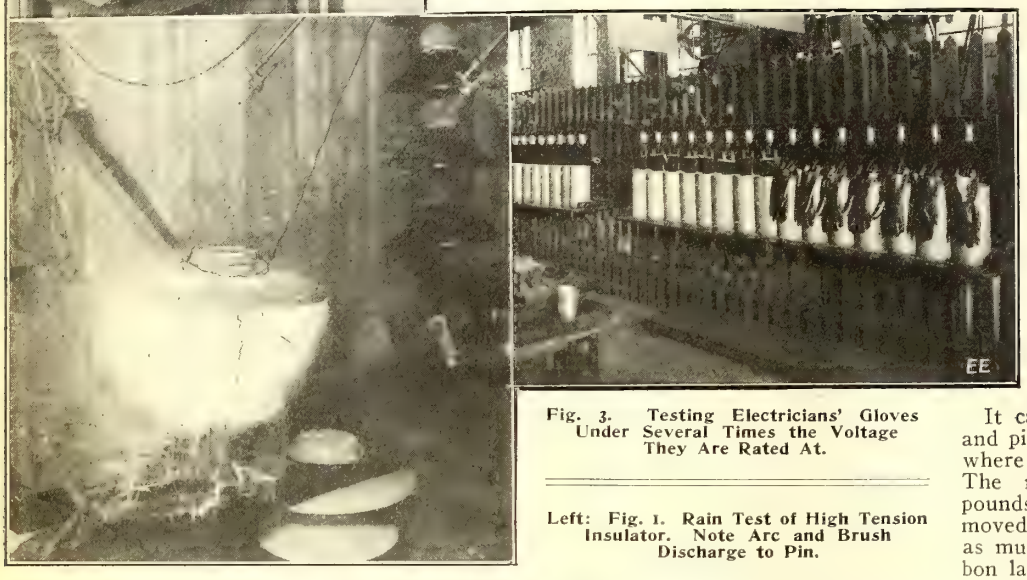


Fig. 3. Testing Electricians' Gloves Under Several Times the Voltage They Are Rated At.

Left: Fig. 1. Rain Test of High Tension Insulator. Note Arc and Brush Discharge to Pin.

Fig. 1 shows a large high tension transmission line insulator under an artificial rain test. This test is made to determine the performance of the insulator when exposed to heavy rain and wind conditions of weather, so as to determine how it will operate under the most unfavorable conditions which it may be called upon to withstand. This insulator is being tested to determine the point at which an arc will form around the insulator. In this case it is about 130,000 volts. Water is applied in a fine spray from nozzles at an angle of 45 degrees from the plane of the insulator, the amount of precipitation being one inch in five minutes. Many such insulators are purchased subject to the Laboratories' inspections and tests, the Laboratories' inspectors being sent to the insulator factories to make the tests in order to facilitate shipment. At this time over 750,000 insulators have been submitted to the Laboratories' tests.

Fig. 2 shows two generators giving a current having a pure sine wave shape. They are known as Vreeland sine wave oscillators and are used in testing at telephonic frequencies. The two machines are of similar construction, consisting of a mercury vapor tube so connected to condensers and inductance coils that the impressed *direct current* is transformed into a *high frequency alternating current.* These inductance coils are the two parallel coils at the back as seen in the picture. The third coil in front is the secondary coil from which the current is taken. The range of frequencies for the two machines as shown is 120 to 3,000 cycles per second. Other frequencies can be obtained by varying the condenser or by inserting other inductance coils.

At Fig. 3 is shown the method of testing electricians' rubber gloves. For this test the gloves are filled with water and immersed in a pan of water, one terminal being connected to the water inside the glove and the other terminal to the pan. The gloves are tested at various electrical pressures, depending upon the service which they are expected to perform. The gloves shown in the picture were tested at 10,000 volts for five minutes. In this test the electrical pressure is great enough to puncture the glove in any part which is defective. Tests of rubber gloves are, of course, vitally important, as the safety of the wiremen who must work on live circuits is on of the first considerations.

The photographs shown merely indicate three of the activities of these wonderfully well-equipped laboratories. There are hundreds of tests made by this company which might be described in the same way if the space would permit. The foregoing is given as a sample of the kind of service performed.

LAST CALL

Beginning with July 1st the subscription price of THE ELECTRICAL EXPERIMENTER goes to $1.00. *It is to your interest to subscribe now while the price is so low.*

CATCHING FLIES BY ELECTRICITY.

Think of it! 5,593,720,000,000 is the normal number of flies a single fly will produce from April 15 to September 10, according to the official statement of Dr. L. O. Howard, U. S. Government expert.

The electrically driven suction fan and cage here portrayed has been especially designed to meet a long felt want and is besides economical to operate.

By looking at the illustration one not familiar with a suction fan can easily comprehend the operation. A powerful suction fan is attached to the motor and the air, dust or insects that may be drawn into this fan are blown into a steel cage. Various types of mouthpieces are furnished with this machine, and extensions of 2-inch pipe can be made in any direction to catch flies, dirt or insects.

The feature of the sponge that is added to this enables one to putrify the atmosphere by water, a little drip cup at the top of the cage, which moistens the sponge, makes the sponge absorb the dirt in the atmosphere. The cage is easily removed. The light attached to the stand is for the purpose of attracting insects at night time, the mirror is placed in position with removable clasps; during the day time any sweet material placed at the openings will attract the flies. It is necessary to provide bait to attract flies. Banana oil or banana peel, stale beer or molasses attracts. It can be set in out of the way places and pipe connections made, or it can be set where most flies or insects accumulate. The machine weighs approximately 30 pounds and is thus portable and very easily moved from place to place. It consumes as much power as a 16 candle power carbon lamp.

The value of this machine to commission men, butchers, restaurants, bakers, slaughter houses and, in fact, any place where flies accumulate cannot be estimated.

Electrical Machine That Attracts and Catches the Terrible Fly.

The D., L. & W. R. R. recently conducted successful wireless telephone tests between a moving trains and station set, over a range of 63 miles, in mountainous country. Regular business made up the messages.

The average person is equivalent to 1/7 of a horsepower, as demonstrated by actual laboratory tests.

An Interview With Nikola Tesla, Electrical Wizard

By Samuel Cohen

THERE is no doubt about it—your heart does beat faster when you are about to meet a famous electrical scientist, one of the foremost in the world. Before you go you don't think so. It didn't beat a second faster when you entered the outer office, perhaps; but as I stood on the threshhold of the big waiting room where Mr. Nikola Tesla does his day's work my nerves were highly strung. Why? Why hadn't I felt like this when I had talked to other great inventors and scientists? I had been impressed, truly, by these men, but not to any such extent as when I entered the room where the master electrical wizard lives; he who has produced electrical discharges resembling lightning bolts.

After a few minutes, I was ushered into the presence of Mr. Nikola Tesla, who stood in the corner of the room awaiting me. I asked him regarding his latest achievements, but Mr. Tesla only smiled and told me first of some of his experiences some years ago, when he produced some of the largest electrical discharges ever attempted by man. He spoke of some of his wonderful experiments with high frequency currents at high potentials, which he made in 1899. The photograph Fig. 1, herewith shown, is one of the large Tesla apparatus for the production of very high frequency, high tension currents. This apparatus was built in 1899 for his plant at Colorado Springs. At this plant and in the same year he made a number of valuable discoveries. Among these was one on which a patent was recently granted to him. This patent covers the method of production of extra large electrical discharges, such as here shown.

This display of sparks will be the more appreciated when it is stated that the streamers from end to end measure 70 feet and the current leaping into the air is 800 amperes, with a maximum potential of 12,000,000 volts. The power supplied to this machine was 300 kilowatts. These voltages are high enough, but Mr. Tesla designed larger apparatus capable of reaching a tension of 100,000,000 volts. A machine of such power must be handled with the utmost care, as the slightest carelessness may kill the experimenter; even if he were at a considerable distance from the machine. Mr. Tesla stated that he had had several narrow escapes while experimenting in 1899, caused by "balls of fire" striking out into the atmosphere.

Top Photo Shows Largest Sparks Ever Produced by Man. Mr. Tesla is Seen Sitting. Seventy Feet Across Spark Streamers. Lower Photo. Mr. Tesla and His Marvelous Wireless Light.

The metal balls of the coil here shown are 80 cm. in diameter. The current oscillates at a frequency of 75,000 cycles per second. Some of these discharges were two and one-half times as large as common lightning discharges, and they could be heard twelve miles away from the apparatus. Mr. Tesla is observed seated and reading one of Faraday's scientific books.

This remarkable man has spent a fabulous amount of time and money in perfecting his apparatus for the transmission of electrical energy without the aid of any wires. The smaller photo, Fig. 2, shows Mr. Tesla holding in his hands a 14-inch glass bulb, which is highly exhausted and containing a drop of mercury. The electrical power received by this tube is obtained from a loop of wire located behind the screen, which is supplied with an ultra-high frequency current. The tube was not connected in any way to the apparatus. As soon as the current was sent through the wire loop a high potential current was induced in the bulb, which vaporized the drop of mercury, causing it to give forth a blinding light of thousands of candle-power. The photograph was taken by the light of this tube, with an instantaneous or snap-shot exposure. Mr. Tesla has a

Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

YOU will chuckle with glee over the latest exploits of Baron Münchhausen. This is no doubt *the* scientific serial of the year. It accomplishes something unusual, it amuses while it instructs you. And by the way: just WHAT makes an apple fall from a tree? And what do *you* know about the mysteries of Gravity? The wily Baron will tell you.

How Münchhausen and the Allies took Berlin

I CONFESS that I put in a bad night after my first wireless telephone talk with the Baron on that memorable December night. My dreams were wild and fearsome and I awoke at frequent intervals bathed in perspiration. The whole thing was so uncanny, so preposterous, that when I finally awoke the next morning I began to really doubt if the whole thing had not been a wild, extravagant dream.

As yet I had not told anyone about Münchhausen for fear of inevitable ridicule, so when noon came around I had become thoroughly convinced that I had dreamt the whole thing from beginning to end. But when I sat down to lunch and my elder brother asked me why I had knocked him down on the stairs on his return from the lodge the night before, I knew that the episode was not a dream after all. So I told my people of my experience and recited my conversation with Mr. Münchhausen. They did not wax very enthusiastic as the story proceeded. When I had finished, my father took a deep breath, gave me a queer look and tapped his forehead with his index finger. That was the extent of his comment. He then gave vent to a disgusted snort and started with the soup.

My younger brother sung to the tune of *"Apple-blossom time in Normandy":*

"When the Nuts are getting ripe in Squirreltown!"

My older brother remarked casually that he had read not so long ago about an eminent Eastern doctor who found that strong wireless waves had the peculiar property of producing little explosions inside of the brain. A coherer action, as it were. This he said produced what the doctor termed a "wireless brainstorm!"

"A rather dangerous disease, closely resembling hydrophobia," my brother remarked, before attacking his stew.

The rest of my family all made similar intelligent comments, and as the case proved hopeless, I kept quiet and said nothing.

That evening, however, shortly before 11 o'clock I summoned the yawning, obstreperous members of my family to the wireless room and installed on everyone's head a wireless telephone headset, which latter were connected to my own trusty receivers. I then told my little audience to watch the clock and be prepared to listen to the most remarkable discourse ever held between two humans. Nor did I disappoint my audience. The clock had hardly finished striking the eleventh hour, when the (to me) familiar high-pitched screaming sound was heard again, and a few seconds later Münchhausen's voice vibrated powerfully in my own, as well as my audience's receivers:

"Good evening, my son," he said in his sepulchral voice, "I trust you have had pleasant dreams and that last night's experience has not disturbed you too much."

I hastened to reply that I was doing nicely, but that I found it difficult of persuading my doubting Thomases that his Excellency had really come back to life. At this Münchhausen laughed heartily and said he had expected that much. He added that if further proofs were wanted, he would be happy to give another lunar exhibition. He volunteered in addition to sweep the moon's dark quarter in any color we desired this very night, in order to convince even the most skeptical that his return was not a hoax. I could tell by the faces of my hearers that they were beginning to become impressed. A vote of the audience held right then and there determined the color to be green. I transmitted this intelligence at once to the Baron, whereupon he promised to light up the invisible dark quarter of the moon in a green phosphorescence for the duration of 20 seconds, beginning at 11.30 p. m. He added that our conversation was to be resumed after the "performance."

We thereupon repaired to the roof of the house, everybody keyed to the highest excitement by this time.

I will not go into lengthy details; suffice it to say that, true to his word, at exactly 11:30 p. m. Münchhausen swept the dark part of the moon's surface with an immense shaft of a green phosphorescence, similar to the exhibition he had given to me the night before. If anything, the light shaft was more powerful; this, however, might have been due to the earth's atmosphere being clearer than on the previous night.

I need not go to the trouble of explaining that every one of my family was thoroughly convinced. All were silent and awe-struck, and all were as ready as myself to believe anything that Münchhausen might say, and I assure you I was convinced throughout.

After the exhibition we resumed our seats in the wireless room, and I suggested that my brother take stenographic notes of the conversation, he being an expert stenographer, having been a reporter on the *New York Times* for five years.

I may add, therefore, that all conversations between Baron Münchhausen and myself, which I shall publish hereafter, are exactly as stated, taken from my brother's stenographic reports. The original notes are open to anyone doubting their truth.

After we had all been seated and the excitement had cooled down somewhat, I started my generator, tuned to 80,000 meters wave length, and spoke into the transmitter before me:

"Your Excellency, are you there?"

"Yes, indeed, my dear boy," it came back in encouraging tones; "now I suppose I will be bombarded with '42-centimeter' questions for the rest of the evening! What? Let it be known, therefore, that Baron Münchhausen is, as usual, ready for all emergencies. Pray, proceed!"

"Thank you, indeed," I responded, gratefully; "you are taking a load off my mind, for I certainly have quite a few questions for you. My first question, most naturally, is, 'How came you to select me with whom to converse?'"

"For two reasons: The first being that I knew you to be a truthful individual, the same as myself, far-famed and known as such in your country. The second reason is because I could hear your wireless signals, right here on the moon, proving to me that you were probably the only one with whom I might converse on Earth. My judgment, as usual, proved correct."

"Thank you for the compliment," I replied. "Now for my most important question: 'How on Earth have you ever landed on the Moon, and why?'"

The Baron laughed outright at my pun, and proceeded:

"That's a rather long-winded story, but I will try to explain.

"As I told you last night, when I came back to life, I had found myself in my old secret room. After my visit to the Mayor I returned to this room and proceeded to remove my treasure of 10,000 gold ducats which I had intended to take with me on my contemplated secret flight 110 years ago. It seems that instinct prompted me to exchange this currency for paper money at a local bank that very day. A lucky thing for me, as you will see shortly. You will believe me when I state that I slept easier that night, with those 20,000 ducats, exchanged into modern thousand mark bills, tucked away securely in my ancient wallet, under my pillow."

"But, your Excellency," I broke in, "did you not say a minute ago that there were but 10,000 ducats?"

"H-m. That's correct," chuckled the Baron, "but, my dear boy, you seem to forget entirely that gold ducats of the vintage of 1790 sell at a very high premium to-day, on account of the great scarcity of these coins! As a matter of fact, if I had peddled these coins to coin dealers and private coin collectors, I have not the least of doubts that I could have realized a great deal more.

"The next morning I was awakened by a fearful racket. It seems that word had traveled around that I was back to life, and my enthusiastic townspeople were bent on celebrating my return in a befitting manner. There were about ten brass bands in front of my house, and I estimate that at least three-quarters of the population were assembled around the bands waiting to see me. I dressed hurriedly and stepped out on the balcony, greeted with deafening *'Hochs,' 'Vivat Münchhausen'* and *'Lang soll er leben.'* Then someone yelled for a speech, to which I responded, delivering a befitting address for the occasion. I had hardly finished when two ladders were leaned against my balcony and two enthused *'Corps Studenten'* had carried me bodily down into a gala automobile, bedecked gaily with bunting. One of the students, in full dress, took his seat at the steering wheel, while ten others, also in full dress, started to pull the automobile in a triumphant entry through the city.

"It was indeed a strange cortege, and you will find a full report of it in the German daily press of September the 30th, 1907. The town was decorated with flags from end to end in a most elaborate manner, and after a wonderful day full of speeches and all kinds of honors bestowed

upon me the day was befittingly closed with a tremendous illumination and exquisite fireworks. The next few days were crowded with hundreds of interviews to the press and with private individuals, while attention and kindness were showered over me unendingly. I tried hard to absorb all the new customs, and I had to ask numerous questions in order to become acquainted with all the strange things I met at every hand. As usual, my well-known versatility carried me through everything successfully, and it took me less than a week of concentrated study to become a fully up-to-date man.

"There was only one point on which I remained obdurate. This was my attire. I refused to clothe myself in modern clothes. I refused to put my beloved lower extremities into those foolish, modern, overgrown sleeves which you call trousers, nor could I see a single good reason for wearing those unsightly sacks which you call coats. Neither did close-cropped hair, which destroys the individuality of man, appeal to me in the least, nor, for that matter, those fantastic straw-stalk dishes which you call straw hats. Accordingly I stuck to my style of dressing, although I confess I had considerable difficulty in finding a tailor and a hatter who could accommodate me.

"Alas! my triumph was short lived. I told you already that before I had begun my century-long sleep I had committed a certain political offense against the then reigning authorities. You would naturally think that after a lapse of 100 years most any kind of political offense would be forgotten and outlawed. Not so in my dear fatherland. In Germany a political offense is worse than a thousand murders. Official Germany, or rather Prussia, knows no time limit when it comes to *lese majeste*. To make a painful story short, one nice autumn morning I was awakened roughly with the pleasant remark:

"'I arrest you in the name of the King.' Knowing me as a resourceful character, the authorities had sent no less than six well-armed *'Polizisten,'* to make sure I would not break away.

"I was made to dress in a hurry, and before I knew it I had been placed in the 'green wagon' and hustled to the local jail, there to await trial for my political wrongs committed 110 years ago. So does Prussia treat its famous men! Luckily for me that I carried my money in the folds of my high boots, for if I had not, they certainly would have found it. So you see ancient dress has its advantages.

"I stayed for two days in that prison, and I confess that I do not know what would have become of me had it not been for my many sympathizers and admirers. To the credit of the German people's fair-mindedness, distinguished from German officialdom, let me state that I owe my release. For at the end of two days, in the middle of the night, some 30 masked young men, all admirers of mine, rushed into the prison and overpowered the keepers and attendants, and I was put in a large automobile and rushed away in the dead of a moonless night. I was quickly conducted to a small town, where I lived in disguise for some weeks.

"Subsequently I made my way to the Dutch frontier, where I breathed easier, for I knew that I was safe from all danger here. The next day found me in Paris, where I settled down in one of the suburbs, with deep bitterness in my heart against official as well as officious Prussia.

"For the next few years I traveled extensively in Europe and America, as well as the rest of the world (with the exception of Germany), and in the course of my travels I had a great many adventures, which I hope it will be my pleasure to relate to you in the near future. Returning to Paris in 1910, my mind, which had always been of a scientific bend, turned to the study of electricity and chemistry, as well as to general physics, and in a short time I had made hundreds of wonderful scientific discoveries. Not believing in patents, especially in France, with her antiquated patent laws, I patented none of my inventions. Some day I hope it will be my pleasure to publish all of them for the benefit of humanity.

"The outbreak of the great war of 1914 found me in the midst of the study of several new inventions which I was trying to perfect. But I welcomed the war, nevertheless, with a glad heart. Here at last was my long hoped for chance to get even with Prussia against whom I had nursed a growing hate during the past few years. My *'révanche'* was at hand.

"The war had not been in progress for two days when I received an urgent call from my friend President Poincaré, of the French Republic. I called at once at the palace and was greeted cordially by the President, who shook me warmly by the hand. Only one other person was present, namely, General Joffre, chief of the French army, whom I had known intimately for the past few years. He also welcomed me and patted me affectionately on the back. I could see by the expression on their faces that some very serious business was to be transacted, and I did not find myself mistaken.

"'*Monsieur le Baron,*' the President began in a businesslike manner, 'from our past acquaintance I know you to be on our side, despite the fact that you are a born Prussian. Am I correct in my assumption?'

"'Yes, *Monsieur le Président,*' I replied fervently, 'it was my misfortune to be born in Prussia, but I assure you that there is to-day no more ardent, patriotic Frenchman in France than myself. Down with the tyrant Prussia!'

"'*Très bien,*' the President replied, gratified. 'I thank you. I will have you sworn in at noon to-day. As I know that you have made certain far-reaching inventions, I trust that you will do your utmost to turn these to the benefit of our great Republic. Any assistance which you might require will be given to you by the Government, and you will co-operate with General Joffre to destroy the enemy.

"In Less Than One Second Over 500 Men Were Baled Together Tighter Than a Bale of Compressed Cotton.

"'The French General Staff has already decided to invade Germany, by way of Alsace, in order to regain our lost provinces. Your efforts for the present, therefore, should be confined to that territory until your presence will be required elsewhere.'

"I thanked the President profusely for his great confidence in me, and hastened to answer him that I would not rest till the enemy was destroyed. I made it a condition, however, that I should have the power of requisitioning anything, no mat-

ter what it might prove to be, if in my opinion it was essential to use it at the front. This President Poincaré promised gladly.

"'All the Government desires, just now,' he closed, 'are results and victories over the enemy. France is at your service.' With these words we shook hands solemnly and the President left me alone with General Joffre.

"For several hours Joffre and I discussed various phases of the war, and after I had thoroughly acquainted him with some of my revolutionary plans of warfare we parted in high spirits.

"That very night I requisitioned every tank of laughing gas, as well as every carboy of chloroform, in the whole of France. I furthermore ordered every factory producing these articles to work overtime for 24 hours each day until further notice; immediately thereupon I requisitioned an immense factory at Levallois-Perret, a suburb of Paris, where for the next few days I kept 8,000 people busy manufacturing my requirements.

"You know, of course, of the French invasion into Alsace at the beginning of the war, and how we penetrated even beyond Mülhausen and Kolmar. But did you know how it was accomplished, and by whom? I think not. When history is finally written you will find that it was I who make the difficult work possible. I personally conducted the invasion and it was, indeed, a brilliant success. The first clash with the Germans was spectacular. We rushed upon them in the early morning, but instead of our artillery using the ordinary explosive shells we used my compressed laughing gas cylinders. These were constructed in such a way that they would open upon striking the ground. The soldiers of the rank and file were equipped with a similar device, who, instead of shooting bullets, shot compressed laughing gas cylinders. These cylinders were shot from the rifle at a rather close range and were not supposed to penetrate the bodies of the enemy. Instead, the cylinders had a soft rubber nose which, upon striking, actuated a trigger, and this in turn opened the forward end of the cylinder, releasing the gas.

"Our first attack proved as great an astonishment to us as to the enemy. When we began shooting the laughing gas at the oncoming ferocious-looking Germans their expressions changed suddenly to abominable grins. Most of them reeled and dropped right in their tracks; we had but to pick them up afterward as prisoners. I remember in a single day we thus captured 8,000 Germans.

"After the first rush we drove them back to their second line of trenches, and it was here where my chloroform bombs did wonderful work. Our artillery began shelling the trenches with my bombs; these, on striking the ground, liberated the compressed chloroform with disastrous results to the enemy. We literally drenched the Germans with chloroform, and those not killed outright were picked up later to be sent to France as prisoners, where they were put to work at manufacturing more laughing gas and chloroform with which to capture their countrymen.

"Thus we fought our way to Mülhausen, which we occupied triumphantly. I have no doubt that I would have fought my way across the Rhine, but just then Joffre got into trouble in Belgium and retreated into France. On his urgent representation I rushed to his aid, leaving my Eastern army in the hands of a young General whom I thought capable of continuing our Alsatian invasion.

"Unluckily, the Germans became wise to my bombs and began using some form of diving helmets, fastened over the heads, which kept the fumes and gases from their noses and mouths. This of course counteracted my bombs and made them obsolete. The Germans subsequently appeared in great force and drove my Alsatian invading army practically from Alsace, finally leaving it entrenched in the Vosges.

"In the meanwhile General Joffre had retreated almost to Paris before I could rush assistance to him. I am proud to state here that had it not been for me, Paris, as well as the rest of France, would have been in German hands. But Germany had not included Münchhausen in her plans of invasion.

"The great German General Von Kluck was but a few miles from Paris when I went into action. For a long time it has been a deep mystery to many people why he did not take Paris at that time and why he retreated so mysteriously and with so much haste beyond the rivers Marne and Somme. The explanation is found in the one word: Münchhausen. I had long since discovered that the German advance could not be stopped by ordinary means, so I adopted extraordinary measures.

"As is well known, France had been poorly prepared for the war. While there were unlimited stores of powder and guncotton, the artillery was sadly deficient in shells and our soldiers lacked bullets. As the manufacture of these important items is rather slow work, I commandeered all the French arsenals to turn out immediately rock salt shells and cartridges, which, instead of having bullets at their business ends, were filled with a goodly charge of the inexpensive as well as plentiful rock salt.

"From the minute these 'Salties' (as they were called affectionately by the French army) came into use the German advance had come to an end. We simply shot salt at the Germans.

"You may laugh at this and ask how it could have possibly stopped them, but the answer is as simple as it is surprising. The rock salt, when shot from a rifle or gun, had not enough piercing power to penetrate the bodies of the enemy, but it went easily clean through the soldiers' uniforms and then buried itself under their skins.

"If you have ever had a salty solution applied to an open wound you will appreciate what happened when I began pumping rock salt into the Imperial German army. No sooner had a soldier been shot than he would throw up both hands and begin to scratch himself furiously, with a zeal with which you would hardly credit the slow-moving Germans. Orders or no orders from his officers, *Hans* would scratch himself for dear life to get some satisfaction from the fearful itching. Finding that this did not bring the desired relief, instinct prompted him to run for the nearest water supply in order to wash the slight wounds free of the salt.

"By that time our gallant Frenchmen or British were upon them and they were made prisoners in less time than it takes me to describe it. It was quite a few days before the German General Staff got onto my latest device and promptly set out to checkmate me. One morning I received a report that my rock salt charges no longer acted in the usual prescribed manner, i. e., the Germans refused to scratch themselves when shot at. Instead, they threatened to drive us back. That afternoon we caught a few Germans and the mystery was cleared.

"The foxy German General Staff had ordered each soldier to wear TWO uniforms, one put on top of the other! Our rock salt charges could easily penetrate one uniform, but not two! Therefore I was forced to abandon my 'Salties,' and I turned my fertile brain in new directions.

"In a few days I was back to the front with a brand-new device. I am proud to say that of all schemes this one was probably the most effective. With its help we captured no less than 31,986 Germans in less than one week. President Poincaré personally attached the cross of the *Légion d'honneur* to my breast with the official thanks of the Republic. I am immensely proud of it to-day.

"As you will have noticed, all my own devices of modern warfare are exceedingly humane. If I can possibly avoid it I do not allow blood to be shed. I believe in taking the enemy alive.

"My well-known success, the *Human Self-binder*, illustrates this point.

"You are, of course, acquainted with the self-binder as used in harvesting. You know how the machine bales the wheat, putting a stout cord around the circumference of the bundle, holding the stalks together securely.

"This is the principle used in my *Human Self-binder*. It is simplicity itself and works as follows:

"Two of the famous French 75-millimeter guns were placed about 150 meters apart from each other, facing the oncoming enemy. The guns were loaded in the usual manner except that the shells were equipped with an eye-ring at the end facing the enemy. To this ring was fastened securely a strong but flexible steel cable about as thick as your little finger. Before firing, the cable would run into the mouth of the first cannon, while the other end of the cable was fastened to a similar shell in the second cannon 150 meters distant. Then the two guns were adjusted in such a manner that the cable was almost taut; the cannons themselves were leveled almost parallel to the ground. When the command was given the two cannons were fired simultaneously by means of electricity. The result was fearful when we first tried it on a regiment of charging Germans.

Can You

write a snappy, short story, having some scientific fact as its theme? If you can

Write

such fiction we would like to print it. The story which is appearing in the ELECTRICAL EXPERIMENTER at present has aroused so much enthusiasm among our readers that we have decided to publish more

Stories

from time to time. If you have the knack, try your hand at it. It is worth while. However, please bear in mind that only scientific literature is acceptable, altho not necessarily dealing with electrical subjects. "Baron Münchhausen" is a good example. Suppose you try. We pay well for such original stories.

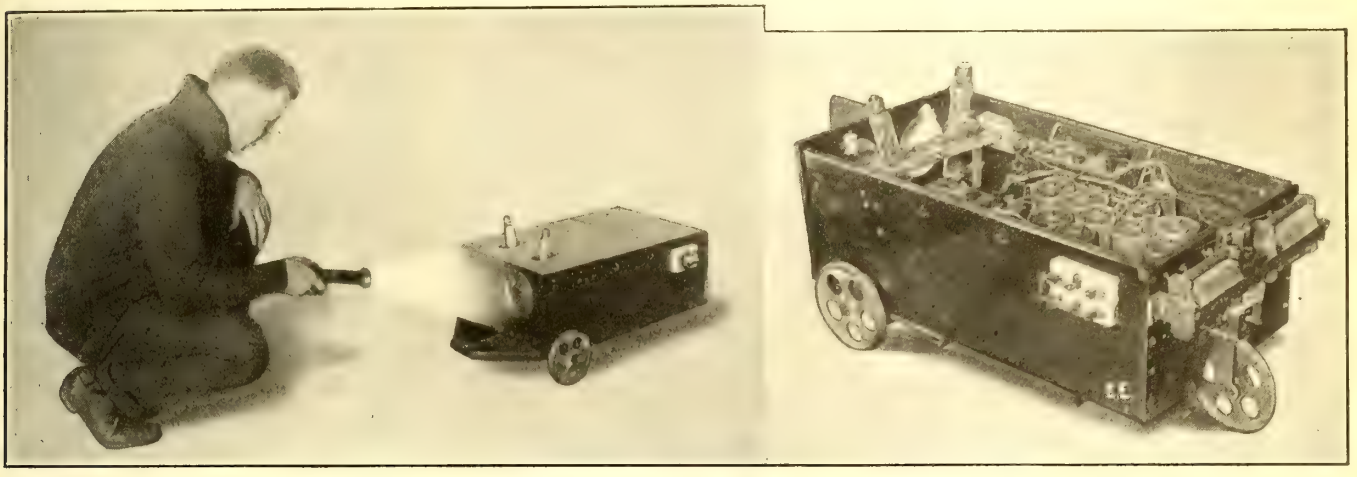
"Electrical Dog" Follows Beam of Light

THE "soul yearnings" of a brand-new animal were recently expressed before a large and enthusiastic audience in the Auditorium, Chicago.

This new matinee idol is 'Seleno," the Electrical Dog, created and trained by B. F. Meissner, of U. S. Navy wireless and torpedo fame.

Seleno believes in hitching his wagon to a star; although a "star" himself, he follows a guiding light ray with absolute fidelity, a veritable chemico-electro-mechanical successor to the Magi of old.

Seleno is a barkless, biteless, hairless, tailless, semi-immortal phenomenon whose appetite calls only for currents—electric currents—that is—volts and amperes. His digestive apparatus is a storage battery, "fed" from the lighting circuit whenever he feels hungry. He moves on rubber-tired wheels in pursuit of the *beam of light* which he "sees" by means of two four-inch condensing lenses which constitute his eyes, and a pair of selenium cell optical brain centers. An electric motor actuates his drive gear and electro-magnetic relays control his course. His nose plays an important part in his following" ability, inasmuch as it is a thin opaque plate located between his "eyes," which shades one or the other eye when the light beam is not coming from directly ahead of him, causing his selenium optical centers to be unequally affected, the principle underlying his steering ability.



The most fanatical "Sun Worshiper" has nothing on Seleno. He would pursue a beam of light to its source, even to destruction; wherefore his master has endowed him with a reversing trigger as a preventive against suicide.

The few Chicagoans who have already been privileged to be present at a private recital by Seleno enthusiastically agree that he is beyond all question a "hound."

Mr. Meissner has developed several understudies, accomplished relatives of Seleno, who "support" him in his "act," demonstrating the remarkable properties of selenium in other startling ways. These lesser stars resolve the mystery of Seleno's fanaticism. A beam of light, directed upon a selenium cell, which is a non-conductor of electricity in the dark, lowers its resistance to the flow of current instantly; so in connection with a relay (or electro-magnetic switch), it can control the energy supply of any electrical device, from a simple incandescent lamp to an electric locomotive or smelting furnace. Likewise, it has been proved in Mr. Meissner's experiments that the deadly naval torpedo or even an automatic bomb-dropping aeroplane can be maneuvered in action from ship or shore by the same wonderful controlling agency.

By means of a small hand flashlamp directed at the "dog's eyes" (lenses behind which are mounted selenium control cells), his master causes the curious box on wheels to follow him about the stage, turning corners and avoiding chairs with no other control than that of the beam of light. By reversing a switch on the "dog" the mechanism was similarly made to back away from the source of light. The "dog" in each case started into motion quickly when the light was thrown onto its lenses and stopped just as promptly when the lamp was extinguished or turned away.

Storage cells inside the case furnish energy to drive the motor which propels the "dog." Each of the selenium cells behind the eye lenses controls a relay which actuates the motor and one of the two steering magnets at the rear of the device. Illuminating a cell on one side starts the motor and turns the rear wheel to that side; illuminating both cells equally causes the mechanism to run straight forward. Thus the action of the control mechanism is to keep the two lenses always equally illuminated and pointed at the source of light—in whatever direction that source moves.

"Seleno," the Electrical Dog, Obeys His Master Faithfully. Righ Hand View Shows Inside of the Dog.

BARON MÜNCHHAUSEN'S NEW SCIENTIFIC ADVENTURES.

(*Continued.*)

The two shells leaped forward together from the cannons, carrying the steel cable with them, now stretched taut. The cable, cutting through the air at a tremendous rate of speed, made a frightful, screeching noise. It 'sang' so loudly that it was easily heard over a distance of 35 miles. It was awe-inspiring.

"Have you ever as a child swung a cord with a stone at one end? If you have, you will have noticed how the string 'sung' louder and higher in pitch as you increased its speed. So it was with the steel cable, only the sound was increased a few billion times over that of your string. It went somewhat like this:

WHHEEEEEEEEE EEEE-EEE-EEE eeeeeeeee eeeeeee e e e e ehh . . . . . .

"The two shells then plowed their way through a few dozen soldiers, while the cable, catching the foremost men amidships, as it were, was stopped short, while the shells, carried forward by their momentum, continued to travel in their forward movement until stopped short by the cable. However, the momentum then carried one shell around to the left, while the other went to the right. In less than one second over 500 men were baled together tighter than a bale of compressed cotton, and as helpless as the latter. Most of the men at the point of contact with the cable were, of course, crushed to death by the tremendous pressure, but those on the inside, while nearly all of their breath had left them for the time being, were alive and were easily made prisoners by us.

"You have probably often wondered why, after the retreat of the Marne, the Germans dug themselves into their famous trenches. The answer is that this was the only means of escape from my human baler. As soon as they had found that they could not rush at us over the open terrain they went into their trenches, which naturally put my self-binder *hors de combat*, or out of business, as Americans are fond of saying.

"This put me at my wits' end for a few weeks, but not for very long. At the end of October, 1914, when all efforts to oust the Germans from their trenches had failed, I went to see General Joffre and said to him:

"'My dear General, we must now resort to a novel means in order to crush the enemy. Here is my plan: The Allies are now spending untold millions each day and no headway is being made against the Germans. Why not take 20,000 picked men, who know how to dig and mine, and order them to build a few gigantic tunnels right under the German trenches, emerging in some forests miles behind the German lines? Upon a given signal our armies would break through the openings and, while half of our men would fall into the enemy's back, the other half would be well on the road to Berlin. Simple, is it not?'

"General Joffre's enthusiasm over my plan knew no bounds. This otherwise silent man fell around my neck and embraced

(*Continued on page* 72.)

The White Feather

WIRELESS on the stage is not a novelty any more in these days. In the past, it has been used to a large extent to key up an audience in order to picture the emotions of a ship's wireless operator either when his own ship is in distress or when he is engaged in rescuing another ship. This phase having been worked to death, Messrs. Lechmere Worrall & J. E. Harold Terry left the beaten track and present us with the *Spy Wireless*.

"The White Feather," now running in its third month in the Comedy Theatre at New York, draws nightly large crowds, who seems anxious to enlarge their knowledge with the workings of the modern wireless spy.

The action takes place in an English town somewhere near the coast. Mrs. Sanderson and her son, both naturalized Germans, run a boarding house, but they are spies in the employ of the German government. Christopher Brent, an Englishman, considered an idiot by all, is a boarder. Everybody upbraids him, and a patriotic girl offers him a white feather as a token of her disgust, because he has steadfastly refused to enlist, nor can he offer a good excuse why he stays at home. He is, however, —Sh-H— a secret spy in the employ of the British government!

Left alone in the parlor, he empties the ashes from his pipe by knocking the latter against the casing of the fireplace. It sounds hollow. Very queer! Brent starts to thinking. He fumbles about the grate for some time and accidentally touches a secret spring, and— presto, the fireplace, which is but a dummy, swings upon its pivots and lo— a neat little "wireless" pops out, as faithfully depicted in our illustration.

The "wireless," made entirely of *"Electro"* instruments, is of course only an amateur outfit and is used by the Sandersons in transmitting important messages to the German submarines, lying outside the harbor, but a few miles distant from the house.

Whereupon Brent uses the outfit himself, gets all the information he needs by wireless and proceeds to put the outfit out of commission by wrecking the detector. Then he swings the outfit back into place and later on, by means of the knowledge thus obtained, also using a Detectiphone to good advantage in the evening, he finally rounds up the spies in a spectacular as well as exciting manner, wins the girl who almost became convinced that he is a coward and everybody is happy ever after.

Also, be it said here, Christopher Brent, who in everyday life is plain Mr. Albert Brown, is the "whole show." He has a difficult rôle and he acts it admirably.

A Breathless Moment in the Play, "The White Feather," When the Hero Picks Up German Spy Wireless Messages.

Six thousand eight hundred miles of hard-drawn copper wire was used in the recent long-distance telephone test between New York and San Francisco.

ELECTRICITY IN PLANT LIFE.

Some plants are electrically weak, others are strong, says Royal Dixon, author of "The Human Side of Plants," in the *Edison Monthly*. Perhaps the strongest; that is, in the sense of electrical vibrations,

An Electrically Sensitive Plant, Known as the "Mimosa Pudica."

is the sensitive plant (*Mimosa pudica*) shown in the illustration. Others, such as iris, nicotiana, nasturtiums, and practically all the meat-eating plants, such as the "Venus fly-trap" and the "sundew," afford splendid examples for experimentation. If any of these be placed "in connection with a galvanometer by means of electrodes attached to leaves on different sides, and one side of the plant be exposed to sunlight while the other side is kept shaded, then within from three to 10 seconds after exposure to sunlight there will be a flow of electricity from the lighted to the shaded parts amounting to .005 to .02 volt. This continues for about five minutes, when the magnet begins to swing back and shows an opposite current of considerable magnitude. The manifestations are similar to those of "teranized nerve."

A better understanding of the electrical qualities of plants will, no doubt, explain many of the hitherto mysterious habits of meat-eating plants. Especially will this be true of such terrible and uncanny plant monsters as the "devil's snare" of South America and the mammoth Utricularia, or fishing plant, which lures minnows and small animals into its voracious mouth, and suddenly, as if an electric button were secretly pressed, closes in upon its helpless prey. In other words, it fishes with a net electrically wired! Strange as it may sound this plant safeguarded itself by means of its electrical currents ages before we used the electric burglar alarm and door bell. Were it not for this protection, the plant could not live and hold its own in such an aurial-infested region as it needs for its fishing ground.

Many strange stories are told of a vampire vine, commonly known as the "devil's snare," which grows near Lake Titicaca in South America. This uncanny vine is like a huge snake and it is supposed to be able to capture wild animals as large as dogs and suck the blood from their bodies, just as an insect-eating plant catches a fly and draws nutriment from the carcass. The "devil's snare" is continually reaching out its huge white arms, which draw in every living thing that comes within its reach. This plant thrives in the inland region of the Nicaragua Canal.

A very peculiar plant, and one which has tremendous electrical powers, is the "telegraph plant" (*Desniodium gyrans*). It is a native of India, and each of its leaves is composed of three leaflets; the larger one stands erect during the day but turns down at night, while each of the smaller leaflets move day and night without stopping. They describe by means of jerking motions complete circles, not unlike the smaller hand of a watch.

EDISON RECEIVES CIVIC FORUM MEDAL.

"Inventor and World Benefactor" was the inscription on the gold medal of the Civic Forum which was presented to Thomas A. Edison on May 6 in Carnegie Hall, as a national testimonial. President Butler, of Columbia University, who presided and made the presentation, said:

"This gold medal is not awarded for any particular achievement, but for distinguished services and great scientific achievements and in recognition of a great career, which has a place among the very highest in the roll of human history."

A brilliant assemblage of world-famous engineers and scientists were present on this great occasion.

Guglielmo Marconi, the distinguished wireless inventor, was present on the platform and said:

"It would be useless for me to say that there is the greatest admiration for Mr. Edison in Europe. If anything, it is greater there than here. Americans may well be proud of the fact that Mr. Edison is an American. I am glad for us Europeans that Mr. Edison belongs to the world."

Letters from ex-President Theodore Roosevelt and ex-President William H. Taft, Alexander Graham Bell, and others were read by Robert Erskine Ely, a trustee of the Forum. Those who lauded the work and personality of Mr. Edison in addresses were Nicholas Murray Butler, ex-Governor J. Franklin Fort of New Jersey, George McAneny, Guglielmo Marconi, President Richard C. Maclaurin of the Massachusetts Institute of Technology, Charles A. Coffin, chairman of the board of the General Electric Co., Dr. John A. Brashear, the Pittsburgh astronomer, and Dr. Charles P. Steinmetz.

Percy Mackaye recited a poem he had written for the occasion. Here are the opening stanzas:

A thousand leagues on the Arctic sea
A ship went down through the frozen floe.
Captain and crew they watched her go:
They ran her colors free;
They cheered her lustily;
And far peoples chanted her praise with them
Where a phonograph, from her plunging stem,
Pealed to the stars her requiem.

A thousand leagues through the Afric wood
A man went looting the jungle's wealth:
Leopard nor lion could stay his stealth,
Nor sleeping-death nor flood:
He drew not the monsters' blood,
But he led them alive through the scorching day
By a tape of moving film, to play
With the wondering children of Broadway.

A thousand leagues, or a thousand years,
Are motes in the gaze of the seeking mind:
By its own radiance thought can find
Its way to ultimate spheres
Dark, till its beam appears
To blazen them. So on that beam hath run—
Round Arctic moon and Afric sun—
The electric mind of Edison.

The medal, which is one awarded annually by the Civic Forum for distinguished public service, was massive and elaborate. Last year it was awarded to Col. Goethals.

On July 1st the subscription price of the "E.E." goes to $1.00. *Subscribe now.* *See page* 38.

The Tower of Jewels at Frisco's Exposition

The Tower of Jewels, the dominating piece of architecture of the entire Panama-Pacific Exposition, is shown here, illuminated for the first time. That it does not belie its title is evidenced by its beauty when it is illuminated. There are 125,000 jewels or novagems used to decorate the tower which stands on the Avenue of Palms, and is the work of McKim, Mead & White, of New York. Each of the 125,000 jewels is backed by a mirror the size of 25-cent piece. The tower is a terraced structure, the principal features being the gigantic figures of the Philosopher, the Priest, the Adventurer and the Scholar; the work of John Flanagan, of New York. Under the tower are 44 feet long murals by Edward Simmons. This is only one of the many beautifully illuminated buildings at the exposition.

Photo (C.) by Underwood & Underwood.

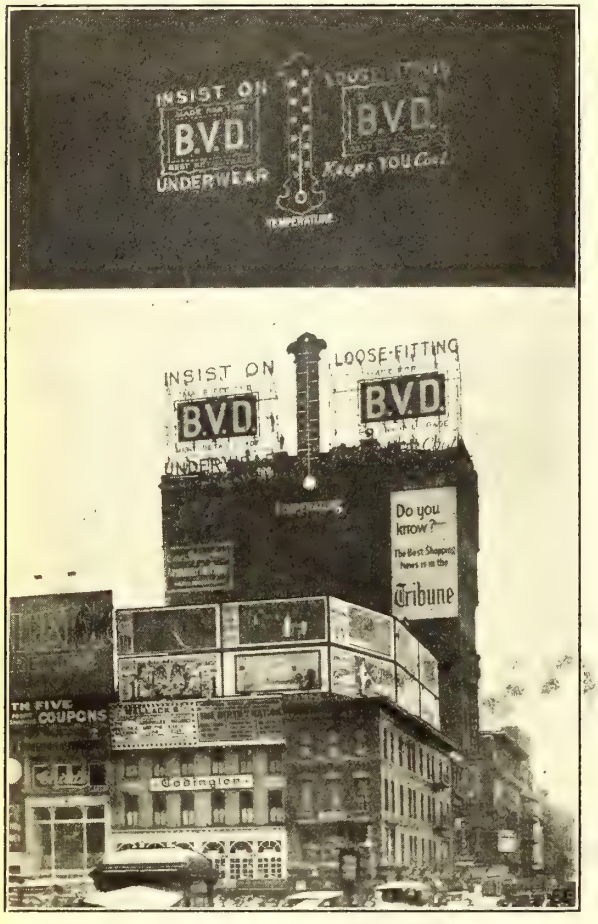
AN INTERVIEW WITH NIKOLA TESLA.

(*Continued from page* 39.)

number of startling new discoveries and inventions in the electrical field, which he does not care to announce at present, and he considers these latter of greater moment than any electrical work he has so far done. He intends in the near future to transmit wirelessly speech and energy around the world from his very powerful electric wave station on Long Island, which is as yet not completed, but which will be finished soon undoubtedly. Mr. Tesla stated, "that the day will soon come when he will show the world that the transmission of power and speech without the aid of any wires is possible."

Mr. Tesla was the first inventor of the induction motor and the system of alternating current power transmission, popularly known as two-phase, three-phase, or poly-phase systems, which created a revolution in electrical engineering and are now universally adopted.



His most important recent work is the discovery of a new mechanical principle which he has embodied in a great variety of machines, such as reversible gas, steam and water turbines, mechanical transformers and transmitters of power, etc. This principle enables the production of prime movers capable of developing ten horsepower, or even more, for each pound of weight in the machine. His present prime mover could be very successfully used in the propulsion of vessels at extremely high speeds, he explained.

The allotted time grew short, and in a few minutes the great inventor bid me adieu and I left the presence of one of the world's most distinguished scientists of whom it has rightly been said: "He lives a hundred years ahead of his time."

AN ELECTRIC THERMOMETER SIGN.

A useful as well as an efficient advertising sign has been erected in New York City at Broadway and 43d street.

This unique sign is designed with a large electrically lighted thermometer, as seen in the day and night photos here presented. The thermometer is ingeniously controlled by electrical switches and circuits so as to always read the correct temperature by day or by night. Hence the Broadwayites can easily ascertain the correct heat value by a glance at the "B. V. D." sign, which can be seen for a considerable distance. Photo by courtesy O. J. Gude Co., the erectors.

Novel New York City Electric Sign Which Tells the Public the Exact Temperature at Any Time, Day or Night, by Means of Electric Lamps.

The size of the sign is 30-44 feet high by 93 feet long. Height of letters in "Insist on Loose-Fitting," 4 feet; of label, 21 feet; of letters "B. V. D." 9½ feet. The entire height of thermometer is 50 feet and its width is 7 feet. The diameter of ball at lower end of thermometer is 3 feet 3 inches.

IS VIBRATION THE BASE OF THE UNIVERSE?

By Garrett P. Serviss.

"Is it true that when a sound is so high pitched that we cannot hear it, it turns into some color, i. e., affects our optic nerve? Is the difference of colors due to the vibrations of matter? May matter itself eventually be resolved into different rhythmic motions?, asks a reader of the *New York Journal*, who has been answered by the noted scientist and astronomer, Garrett P. Serviss, as follows:

To answer your first question, consider these facts:

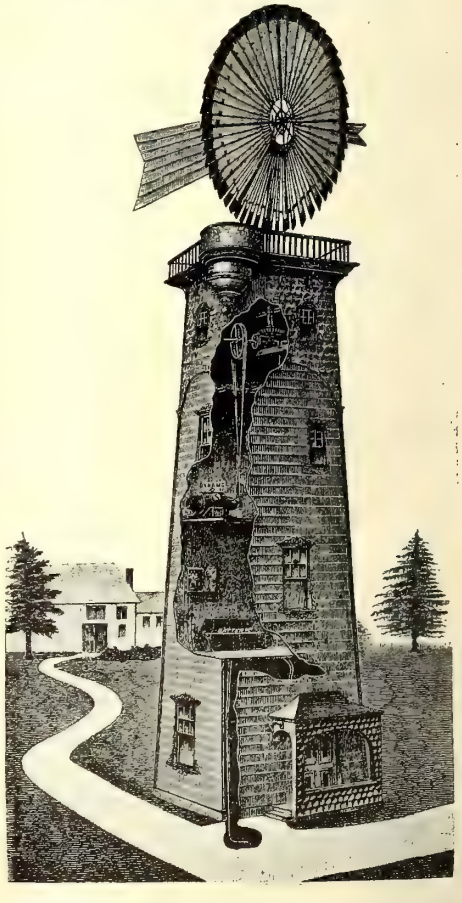
Sound is due to a vibration of matter (either gaseous, liquid or solid) of such a character and frequency that it affects our auditory nerves with a sensation which we call hearing. Ordinary sounds are conveyed to our ears by vibrations of the atmosphere, which consists of a mixture of gases. These vibrations are known as "sonorous waves." According to Helmholtz's experiments, the ear cannot detect any sound if the number of vibrations per second is less than 16 or more than 38,000. But this is an extreme estimate. All ordinary musical sounds are comprised between about 40 and 4,000 vibrations per second, covering about seven octaves. The lengths of the sonorous waves corresponding to frequencies of 40 and 4,000 per second are respectively twenty-eight feet and twenty-eight one hundredths of a foot, the latter being a trifle more than three and one-third inches.

Now, turn to light. Light is due to a vibration of a medium called the ether, or "luminiferous ether," which is supposed to pervade all space, and to pass freely through all matter, while being itself exempt from the ordinary limitations and properties of matter. Just as in the case of sound, the vibrations that give rise to the sensation of light belong to a series of waves only a small part of which possess the requisite length and frequency necessary to affect the organs of sight. It is important to remember the distinction that the "light waves" are in the ether, while the "sound waves" are in the atmosphere, or some other ordinary material substance.

If the rapidity of the vibrations in the ether is less than about 460 million-million per second, or more than about 680 million-million per second, they make no impression on the optic nerve, and we see no light. The wave lengths corresponding with the frequencies just mentioned are respectively aboue one 39000th of an inch, and one 58,000th of an inch.

Within these limits notable differences in the effects produced upon the eye by waves of various lengths occur. These differences are the origin of colors. The longest and slowest of the waves included in the limits named above, produce the sensation of red; the shortest and most rapid produce the sensation of violet; intermediate waves produce the sensations of orange, yellow, green, blue, indigo and intermediate shades. When all the luminous waves are blended together in the eye, they give the effect of white light.

From what has just been said, you will see that it would be impossible for such a direct relation, as your question indicates, to exist between the vibrations of sound and those of light. A sound that becomes so shrill that it passes upward on the gamut beyond the reach of the ear may still be a sound for some creature, like an insect, with an organ constructed to respond to vibrations of very high frequency. But it could not merge into the minute etheric vibrations that produce the sensation of color without itself in some manner passing over from the realm of ordinary matter into that of extraordinary matter, which seems to be occupied by the ether.



The third question leads to speculative ground. I may say, however, that everything at present seems to indicate that motion, of a rhythmic character, does lie at the basis of matter.

ELECTRIC LIGHT FROM WINDMILLS.

Electric lights from windmills may be very economically produced, and, in fact, is produced in this way a great deal in Europe and other countries. This practise is becoming gradually known, and utilized in the United States now; and with an installation costing $75 to $100 a fair size complete lighting plant can be installed for this drive.

Illustration shows a typical windmill electric power plant, including gearing and belt to dynamo pulley; automatic charging cut-out between the dynamo and battery, and the storage battery.

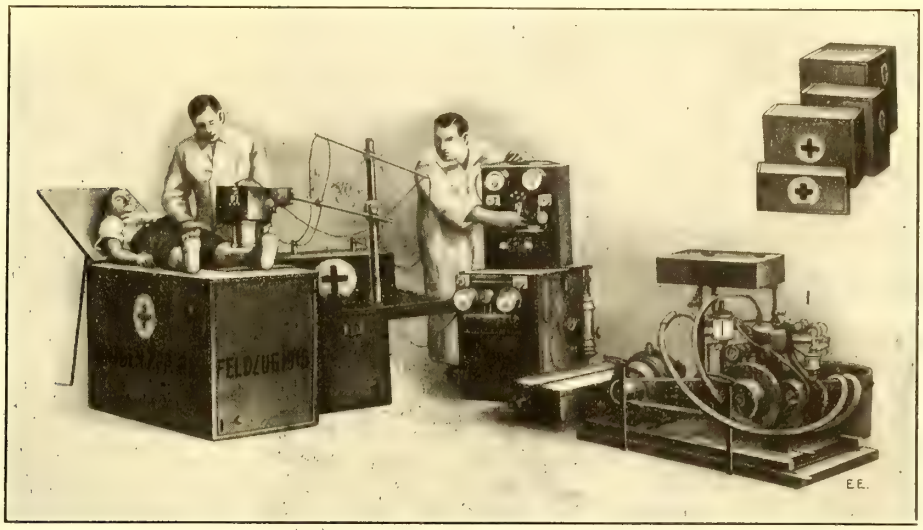
The principle on which these plants operate is quite simple. It is the same as if you had a pipe feeding into a water tank and every once in a while a quantity of water was discharged through this pipe over the top of the tank. In this way, the tank would gradually be filled although spasmodically, and the same principle takes place in the windmill electric power plant. The dynamo, whenever it is run fast enough by the windmill blade, pumps electric current into the battery. In the course of a day, the battery thus becomes fully charged in most cases. The lamps are lighted practically from the battery then; thus preventing any fluctuation in the brilliancy of the lamps, which would take place, of course, if the lamps were lighted direct from the dynamo in this case.

Windmill Drives Electric Lighting Dynamo and Charges Also a Storage Battery.

C. Pinkerton, of Spencer, S. Dak., says:

"Your *'paper'* is a very interesting one and I don't want to miss a copy of it."

Electricity in The War



By Friederich Waldersee

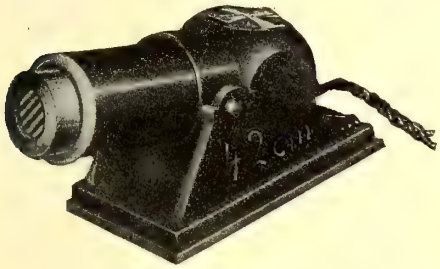
(Berlin Correspondent of the Electrical Experimenter.)

X-RAYS IN THE GERMAN ARMY.

X-Rays have played a very important part in the wonderful medical corps of the German Army. It is probably the most important apparatus in their military hospitals.

One type of X-Ray machine, packed in four portable boxes, is illustrated here. The X-Ray apparatus herewith shown was especially developed by a German company, and six of these machines were transported lately to the Bavarian Army.

Ingenious Compact X-Ray Outfit of the German Army for Field Purposes.

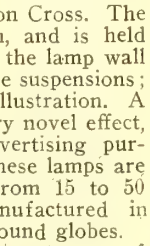


The electrical power, which the 30 cm. induction coil receives, is supplied by a dynamo driven by a gasoline engine. The case No. 1, in which the dynamo and engine is packed, also serves as an operating table when the engine and dynamo are removed, as observed. One side of the case, with suitable bracket arm, serves as an adjustable head rest. The second case contains a millivoltmeter, ammeter, and a a control switchboard. The switchboard is mounted on top of the cover. It is readily removed by turning and placing it in an upright position, which makes it then ready for use. A third case serves as a container for two X-Ray tubes; the case also serves as an X-Ray tube stand and houses the tube diaphragm holder, etc., in transit.

The powerful induction coil which supplies the X-Ray tube with the high tension voltage is sealed very carefully in a special box, in order to stand all kinds of rough use. Another case, No. 4, contains a set of storage batteries for emergency purposes, such as the failure of the dynamo and engine to work.

The apparatus has plenty of work to do, indeed, as it forms one of the surest methods of locating bullets, fragments of shells, etc., which may have entered the flesh and muscles.

NEW GERMAN WAR NOVELTIES.



The two illustrations produced herewith give a good idea how the Germans are exploiting the war, even as to electrical novelties.

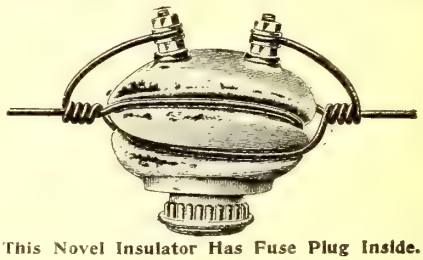
Cigar Lighter in Shape of a Gun.

The electrical lamp reproduced herewith is a tungsten lamp and its filament is shaped in the form of the Iron Cross. The filament is of a spiral form, and is held in position from the sides of the lamp wall by means of the ordinary wire suspensions; these are not shown in our illustration. A lamp of this kind gives a very novel effect, particularly if used for advertising purposes, patriotic fetes, etc. These lamps are at the present time made from 15 to 50 candle power and are manufactured in pear shape form as well as round globes.

Our other illustration represents one of the famous 42-centimeter guns, of which we have heard so much in the war. It is, however, not a gun and only the outside shape conforms to same. It is nothing more or less than an electrical cigar lighter in the shape of a gun; a lamp cord connected to the back of the gun is used to make connection with the electric circuit for 110 volts. A simple arrangement is provided which makes the front end glow as soon as the gun is picked up from its base; the housing is made of a brown zinc casting. The design is very pleasing, and there seems to be a good market for a device of this kind in Germany at the present time.

ARC LAMPS IN HIGH GAS PRESSURES.

It is stated in the "Elektrotechnische Zeitschrift" that Prof. Lummer, of Breslau, Germany, has run arc lamps under pressures of 20 atmospheres absolute, and obtained intrinsic brilliancies 18 times higher than those obtained at ordinary atmospheric pressure, the calculated temperature rising from approximately 4,200 deg. C. to about 7,500 deg. C. The experiments are to be continued.



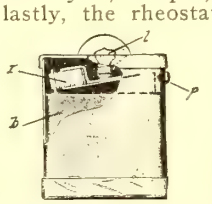
EFFICIENCY OF THE ELECTRIC ARC.

The "Elektrotechnische Zeitschrift," (Germany), shows two developments tending to increase the efficiency of the electric arc. One of these is due to Dr. W. Wedding, who heats the ends of the carbons by means of a flat non-luminous flame, though it appears that the actual function of the flame is to cool that part of the carbons to which it is applied. From the information that is given the arrangement is not altogether clear. It is obvious that if the efficiency of an arc is to be increased, the current density in the luminous part of the electrode must be increased so as to obtain a higher temperature. Evidently this desideratum has been achieved by Dr. Wedding, as the candlepower in a certain direction is raised from 30,000 up to about 100,000 Hefner candles, although the temperature of the carbons in certain parts has been reduced.

The idea of cooling has also been attempted in this country, and in this case alcohol vapor was the cooling medium. From the practical point of view, however, increase of pressure does not seem to be a very promising direction in which to work.

NOVEL GERMAN INSULATOR.

In a recent issue of *Helios,* a German electrical paper, appears the cut here reproduced of a novel porcelain line insulator, which combines means for anchoring



This Novel Insulator Has Fuse Plug Inside.

the two wires as well as a fuse plug. It is suitable for a variety of purposes, such as lighting lines and telegraph or telephone circuits. The fuse connections are brought to two binding posts as perceived.

A NOVEL FLASHLIGHT RHEOSTAT.

A rheostat built in the flashlight is the latest German novelty. This obviates the tendency to burn out tungsten bulbs of low rating used on fresh batteries as seen from the illustration. There is the usual battery b, lamp l, push button p, and lastly, the rheostat r. This adjustable resistance r consists of a few feet of wire wound on a tube, with a slider arranged on the brass piece making contcat with the center or base of the lamp. To insert more resistance, for fresh battery, the coil is removed and the slide moved toward the right. Then it and the battery are replaced. Tungsten lamps of 2.5 to 3.5 volts rating can be used with a battery yielding 4.5 volts when fresh. As the battery ages, the rheostat enables one to adjust the voltage to the lamp as required.

AN OBSERVATION CAR ELECTRIC SEARCHLIGHT.

By Frank C. Perkins.

The accompanying illustration shows the first electric searchlight on a railway observation car, installed on the fast mail train operated between the Twin Cities and Chicago on the Chicago, Milwaukee & St. Paul Railway. The searchlight, 13 inches in diameter, is placed on a pedestal 52 inches high over all, taking up 16 inches of floor space on the observation platform. The carbons are ½ and ⅝ inch in diameter, specially constructed for searchlight work. The carbons stand horizontally and operate automatically after being focused. The lamp is built to operate on a 60-volt electric current, and requires 20 amperes, throwing a stream of light for a distance of two miles.

The Latest Attraction on a Western Railroad Train. A Powerful Searchlight Illuminates the Scenery at Night.

It is stated that the condensed view of the light after leaving the reflector is equal to 4,500,000 candle-power. It will be seen that the lamp is mounted on the observation car platform at the end of the train and it is in charge of an experienced operator, providing a means by which the passengers on the train can view the scenery after nightfall. The St. Paul Railroad runs parallel to the Mississippi River for over 100 miles, and the boats, curious rock formations and the features of the landscapes come out clearly in a very interesting manner by the use of the powerful searchlight. The searchlight can be moved 90 degrees horizontally and 45 degrees vertically, thus making objects visible for a distance of several miles around as the train speeds along.

READER'S VOTING BLANK.

What do you like best in the *Electrical Experimenter?* We don't know. We can only guess. Sometimes we guess right, often wrong.

Will you help us by telling us what appeals most to you? Only by means of your aid can we bring this magazine to perfection. It is easy for us to give you what you like most, *but you MUST tell us.* We will take a vote among our readers and carefully classify results. We promise to be guided wholly by this vote, and will publish the results in the August issue.

Fill in the spaces below by placing a figure in the square alongside of the subject in the order of your preference. Thus, if you like the wireless department best, place Fig. 1 alongside of it. If your second choice is "Patents" place a figure 2 alongside of it. If "Among the Amateurs" is your third choice placed a 3 alongside of it, and so all the way down. This will guide us absolutely. And be sure to give us your *frank* criticism. When the blank is filled out cut it out and paste it on a postal.

It costs but one cent to vote, and you will get just what you like most. So before you turn the page fill out the blank, NOW!

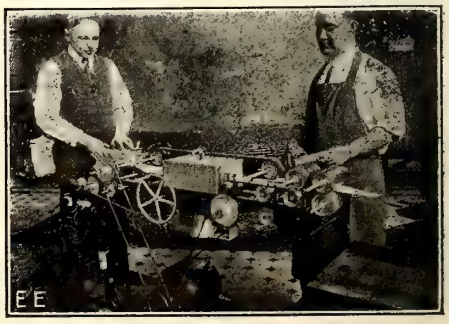
NEW RADIO-ACTIVE ELEMENT.

Prof. Goehring, of the Physico-Chemical Institute at Karlsruhe, Germany, announces that he has discovered a new chemical element which he calls brevium.



He states that brevium is radio-active and results from the disintegration of uranium.

Dr. Sinclair Tousey, expert in radio-activity, says of the discovery by Prof. Goehring:

"There are a whole series of dinintegration products of radium and thorium, and six or eight of these are already definitely known to chemists. Radium, of course, is the best known; another is mesothorium, which is of very great practical importance—more so than perhaps any of the others of the group, with the possible exception of radium. It is used in medicine, especially in Germany, for the same purposes as radium and to a much greater extent, for it is only half as expensive. Also it is only half as active. On general principles it is probable that the new element discovered by Prof. Goehring would have roughly similar qualities to those of the other elements of the group. Inasmuch as the fact that a large number of such derivatives exist was known the isolation from time to time of any one of them is a thing not altogether unexpected in the scientific world."

ELECTRICALLY DRIVEN ENVELOPE SEALER.

A new electrically driven machine which will seal several thousand envelopes an hour has recently been perfected in the Government Laboratories at Washington, D. C. This machine is shown in the illustration, and the operator at the left is feeding a batch of envelopes into the machine. These pass through the various rotating friction drums; as will be perceived, and in the course of their journey, pass through a vapor bath, created by a small vaporizing tank placed at the center of the machine. This vaporizer is operated by a small alcohol torch applied underneath. An electrical heater can be used.

Uncle Sam's New Envelope Sealer.

This device is open to the public, as far as making duplicates is concerned, and anyone may enjoy the benefits from this particular invention without any cost for patent rights.

Electrical Fishes.

PERHAPS in all life there is nothing more interesting than electric animals, and yet but little of their real nature is generally known. Only in this new age of electrical wonders and

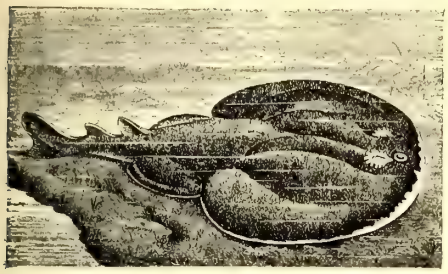


Fig. 1. The Electric Fish Known as the "Torpedo."

miracles have we been brought face to face understandingly with the marvels of nature; to-day we know that every living animal evolves in various ways enormous amounts of electricity. There are both animals and insects that are remarkable electric batteries, strikingly like the electric appliances which we use. Cats give forth sparks of electricity when their fur is rubbed in the dark, and even man himself is a walking electric dynamo.

The most curious of electric animals is a certain fish which discharges shocks at will to defend itself. It is a huge flat fish, known as the "torpedo" (Fig. 1), belonging to the sun tribe, and frequenting the waters of the Mediterranean Sea. Sailors and fishermen tell many strange and weird stories of this sea-electrician. Frequently they claim to have found their arms bound by the invisible and mysterious current of electricity sent up the line by the fish below. Until recent years these phenomena were regarded by seafarers with superstitious awe. Ages before this fish's electrical powers were understood, certain Roman physicians kept large aquariums of them and patients were allowed to touch the "torpedo" and receive shocks, as a means of curing certain diseases.

There are two other electrical fish, each belonging to the fresh water regions of the tropical countries, which rival the "torpedo" in their electrical powers. These are the *Gymnotus electricus* (Fig. 2) and the *Silurus electricus* (see Fig. 3). In each of these fish electricity is developed by specific organs, which are not unlike the form or shape of a voltaic battery.

The electrical organ is used by these fishes in order to catch or kill the prey; also to ward off attacks from other fishes.

In Fig. 4 we show the electrical organ of one of these fishes; this is to be distinguished into two separate parts, namely, the nerves and the special organ into which these nerves branch out. This organ is

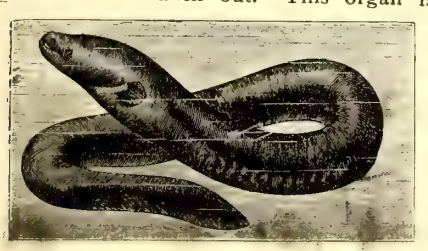

Fig. 2. Electric Eel, "Gymnotus Electricus."

always built up of a great many discs or plates, which, however, vary in size and shape as to the different fishes. These discs or plates are really a curious form of muscle.

At (a) Fig. 4 will be seen the frontal brain from which branch out the nerves (r). Then follows the central brain and after this the small brain and finally the large lobes (b), which form the electrical central, the so-called *"lobus electricus."* From this a great many sets of nerves branch out, which are then distributed over the electrical organ (cc). This takes up much of both sides of the brain, as well as a part of the back. It also occupies a large amount of the forward section of the body of the animal.

The discs or plates mentioned above lay on top of each other and form an organ which can be best compared with a voltaic pile. It is probably very similar in certain respects to Galvani's first battery. In Fig. 5 we show one of these organs, (a) being the nerves as they branch out over the discs.

In Fig. 6 is shown a large magnification of one of these discs. A part of the nerves go to the inside of the disc, then branch out and end in a grain-like mucous mass in the form of small sphere-like cells (bb). Another part of the nerves then branch out into the protecting tissue (cd).

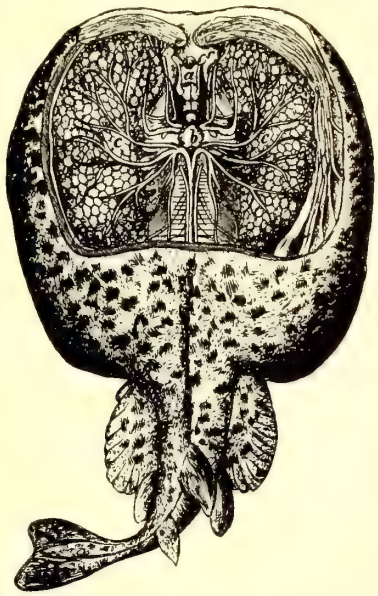

Fig. 4. The Frontal Brain of an Electric Fish.

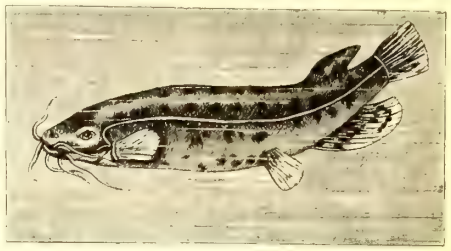
The electrical nature of the shocks of these fishes has been studied experimentally by Walsh as early as 1773. He has shown that, for instance, the *"silurus electricus,"* as shown in Fig. 3, is only capable of giving electrical shocks when the back as well as the belly are touched together. In this case the human body forms a path through which the electrical current passes. Of course, one can get a very strong electrical shock even if one does not actually touch the fish in the above manner with the hands. For instance, a wet rope or any other object which is a good conductor when touched by the hand will transmit the electrical energy when the fish touches it. For this reason it is also possible to obtain a powerful shock directly through the water.

The first shock of one of these fishes is very powerful and sometimes is strong enough to paralyze or even kill a horse. The second shock, however, is already weak, and after a few shocks the fish is not able to give out any more electric energy. It takes quite a time for the fish to accumulate and again charge the cells electrically.

The most formidable of these electricians is the *Gymnotus electricus* of South America. History relates that many fords and rivers have been abandoned because of these strange shock-givers which infest them. The early Indians, who lived near to nature, took advantage of their knowl-



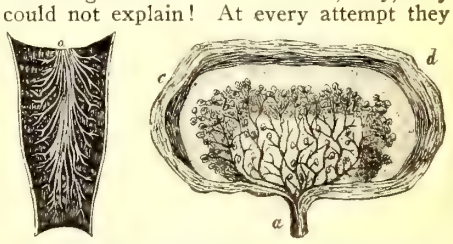


Fig. 3. Another Specimen of Shock-giving Fish Called the "Silurus Electricus."

edge concerning these creatures and caught wild horses by driving them into infested ponds.

The streams near Caracas, South America, are overrun with the much-dreaded *Gymnotus,* and the natives use a strange method of capturing both horses and fish. They call this method "intoxication by means of horses." When a herd of wild horses is driven into one of these fish ponds, the fish are awakened from their slumbers and ascend from the bottom of the water, darting here and there. Their great yellow, snake-like bodies are hurled against the terrified horses, which, with staring eyes and distended nostrils, fiercely paw and kick as they endeavor to plunge their half-paralyzed bodies out of the water. Some of the horses are immediately killed by the electrical shocks of these fish, but the others may be easily captured by the native who is usually mounted on a horse trained for the work. This form of horse catching is very popular.

These powerful fish show a fiendish ingenuity in using their electrical powers. They seem to know the most vulnerable points of attack, for they glide under the horse, give the fatal touch near the heart which acts like lightning, and glide away to safety. This they repeat until their electric force is exhausted, when they float to the surface of the water and may easily be caught.

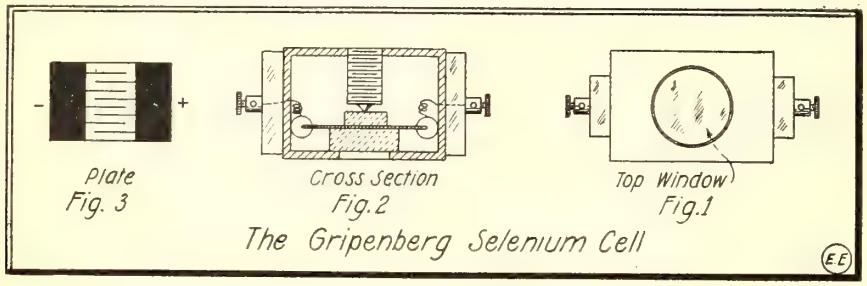
A few years ago, when electricity was not so well understood, and experiments with electric animals practically new, an electric craze went over the civilized world. Electric fish were much in demand; their curative powers were extolled, and hospitals and sanitariums kept them for their patients. Even enterprising showmen and street fakers took advantage of the craze; everywhere were seen aquariums tagged with signs offering big rewards for the one who could lift the fish out of the water. This offer was accepted by numerous strong men, but they never succeeded in removing the fish from the tank, why, they could not explain! At every attempt they

At Left, Fig. 5, Shows Nerves Branching Out Over Disc Organ. Right, Fig. 6, Enlarged View of Sphere-Like Cells of Electrical Fish.

tumbled over from the shock, while the curious crowds jeered and laughed.

As to the power of these electric shocks

(*Continued on page* 50.)



THE GRIPENBERG SELENIUM CELL.

By Samuel Wein.

Of the various forms in which selenium cells have been constructed, the most efficient is that made by William Sebastine Gripenberg.

The cell consists of a small screw-press by means of which a very thin plate of selenium is pressed against the electrodes.

The electrodes are made as follows: A glass plate is covered with a thin layer of gold. By means of a sharp tool, the film of gold is removed in a way as shown in Fig. 3. The electrodes form a fine grating whose bars are at a distance of about 0.35 mm. from each other, and there are 12 to 21 bars per mm.

The properties of the cell depend mainly upon the thickness of the selenium, as the action of light is limited to an extremely thin layer of the exposed surface (calculated by Marc to be about 1/500,000th inch thick). Thin plates of selenium generally give high resistance, high sensibility, and rapid recovery after exposure to light.

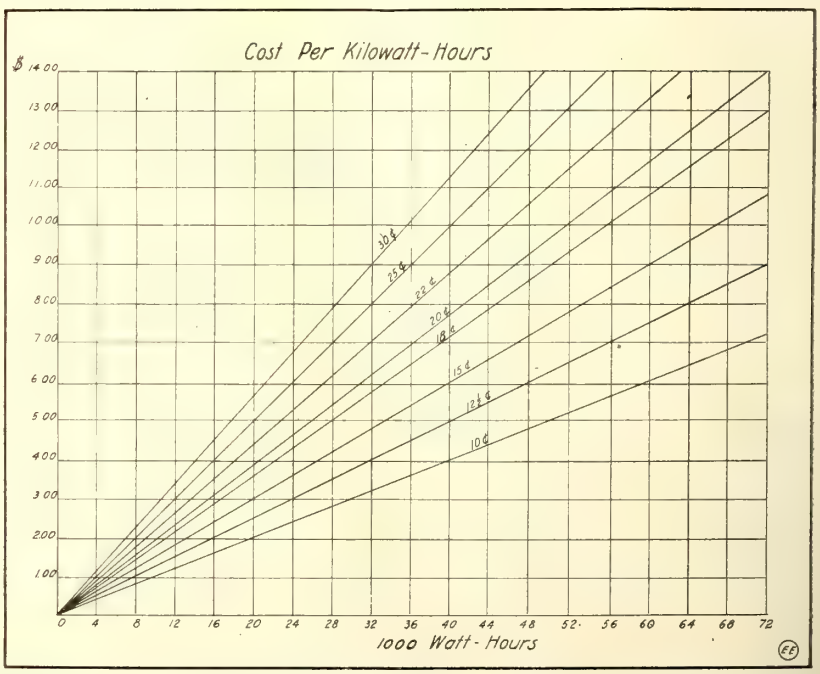
Mr. Gripenberg discovered that selenium, when molten between a cold and a very hot glass plate, strongly adhered to the latter, after the annealing (crystallization). It is thus possible to cover a thin glass plate (1/250th inch thick) with an exceedingly fine film of selenium (between 0.01 and 0.0001 mm.) having a very good contact with the electrodes.

The most important point, however, is that a thin layer of amorphous selenium (less than 0.01 mm.) cannot be converted into metallic selenium by heating, on account of its contraction or decrease in volume (5 to 8 per cent.) and collects in drops like mercury; as soon as a temperature of about 90 degrees C. is attained. This contraction is prevented by applying the selenium with a coat of a suitable lacquer (celluloid Zapoulach).

The conductivity of such cells in strong light may be 1,000 times greater than in the dark. Resistances corresponding to the above thicknesses are the following: 10,000 ohms dark, 2,000 ohms light; 100,000,000 ohms dark, 100,000 ohms light.

Cells constructed according to this method are very reliable and show remarkable constancy, and are well protected from outside influences; moreover, a selenium plate that for some reason has lost its efficiency can be easily replaced by another piece, at small cost. Antimonite having the same photo-electric property as selenium can also be used in the cell.

LOST! ONE WIRELESS MESSAGE.



A complaint of the Berliner Handelsgesellschaft recently stated that a wireless message sent by them to the United States from Eilevese, Germany, via the Tuckerton transatlantic radio station was lost somewhere between the sending point and its destination; New York City. [*Perhaps one of the English cruisers, parading up and down our coast, nabbed it. What?*]

MORE WIRELESS TIME SETS.

A wireless outfit has been installed by Jeweler Prescott, of Oakdale, Calif., for receiving the correct time directly to his office. At noon each day the correct time is sent by wireless all over the country, and anyone having an instrument installed can take the correct time when the signal comes at noon. A set of wireless instruments can be installed in an isolated quarter, where telegraph or telephone lines do not reach, and can receive and send messages and receive the correct time.

HOW TO COMPUTE YOUR ELECTRIC BILL.

Those who use electric current from central station service will find the curves here given convenient in computing the total cost of energy in dollars for various kilowatt-hours. Electrical energy is sold by the kilowatt-hour, usually, which represents about 1 1/3 horsepower used for 1 hour, or ten 100-watt Tungsten lamp load for 1 hour, or a couple of 500-watt electric sad irons for 1 hour, etc. Ordinary 16 C. P. 110-volt carbon filament lamps consume about 55 watts an hour or 10 of them would take .55 K. W. H. To find the K. W. H., knowing the total watts used, divide by 1,000 (1,000 watts equal 1 kilowatt), and multiply by the number of hours the current is used.

To Figure Directly Your Electric Bill; Look Upward on Line Corresponding to Thousands of Watt-Hours Used, Until it Strikes the Slanting Line Marked with Your Rate. From This Intersection Look Over to the Left and Read Total Bill in Dollars.

In the curve chart here given, the base line represents K. W. H. For instance, suppose you use 1,000 watts for 40 hours. Then you have 1,000 divided by 1,000, equals 1 kilowatt and this times 40 gives 40 kilowatt-hours. Suppose your K. W. H. rate is 10 cents. Then, looking up the vertical line until the 10 cent diagonal is reached and following the horizontal intersecting line over to the left, the total cost is seen to be $4.00. Fractional amounts are readily judged or a new chart is readily made by anyone interested on a piece of cross-section paper.

ELECTRICAL FISHES.

(*Concluded.*)

—numerous experiments have proven that they greatly vary in degree; a bird will topple over dead if it chances to light just above a "torpedo." And this is not astonishing when we remember that men are completely paralyzed when spearing these creatures.

The eminent Dutch surgeon, Gramund, found that the effect "produced by the fish corresponded exactly with that produced by the Leyden jar, with this difference; that we see no glitter on its body, however strong the blow it gives; for, if the fish is large, those who touch it are struck down."

Humboldt was one of the first to examine carefully the batteries of electric fish. One tremendous monster was captured near Calabazo, which, by means of its shocks, killed a mule and seriously injured the rider. The huge fish was finally hooked, but the line becoming wet the fish communicated such shocks to the captors that they were powerless to move and were held as though by electric wires. They finally succeeded in bringing the monster to the shore and found that it was twenty-two feet in length. It had practically the same relative size throughout its entire length, with a broad head, compressed tail and the under side of the body lined with four natural electric batteries, two on each side. The strange plates and the batteries were vertical, not horizontal, as in the "torpedo," and each was supplied by nerves from the vertical branches of about four hundred spinal nerves. Such monsters, armed as they are, might well prove dangerous, a touch of their tails frequently bringing sudden death.

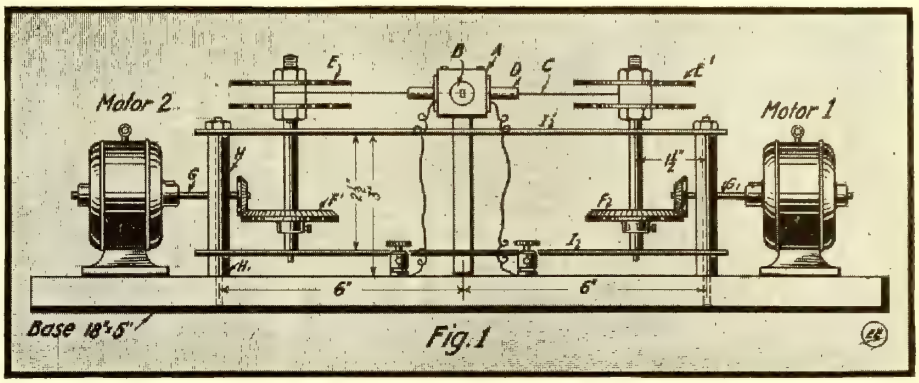
There are unquestionably numerous other electric animals and insects yet undiscovered. Perhaps the time is not far distant when the presence of electricity in all forms of life will be an accepted and proven theory.

How to Build a Telegraphone

By Samuel Cohen

THE telegraphone is an electro-magnetic instrument which records the human voice, music or other sounds on a fine moving steel wire, and these sounds are reproduced as perfectly as in a telephone, if not more so.

The invention of this instrument is due to the researches of Valdemar Poulsen, the Danish Edison, who, while experimenting with the telephone about 1900, discovered a new principle in electro-magnetism which solved the difficult problem of recording and reproducing sound. This principle is the localization of magnetism on a movable steel wire while passing through two small electro-magnets which are excited by some outside source.



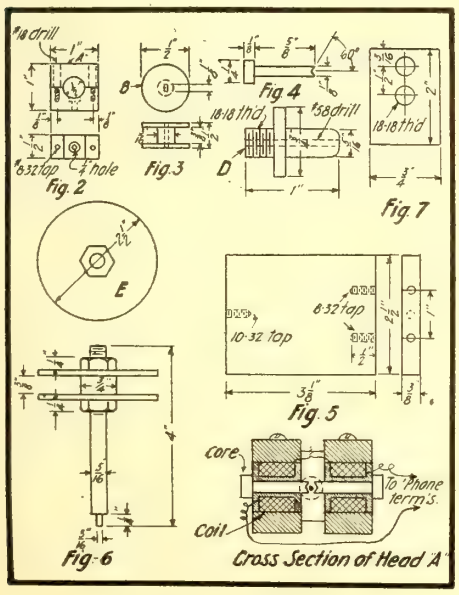


Fig. 1. The Telegraphone Which Can Record Telephonic or Telegraphic Signals on an Iron Wire.

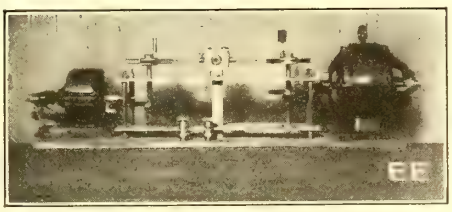
The telegraphone here described was built by the writer especially for the purpose of recording radio-telegraphic and telephonic messages. The writer presents herewith a photograph of the finished telegraphone, and Fig. 1 is the drawing of all the principal parts and their relation to one another in the final assembly.

The details for constructing the individual parts of the telegraphone are given in the accompanying drawings. These do not require much description. By looking at Fig. 1 two aluminum plates I I¹, which constitute the supporting frame of the instrument, are fastened to a wooden base 18x5x¾ inches. These two plates are separated by brass washers H H¹ as shown.



The talking and receiving "head" A consists of two small electro-magnets B B.

Details of Telegraphone.

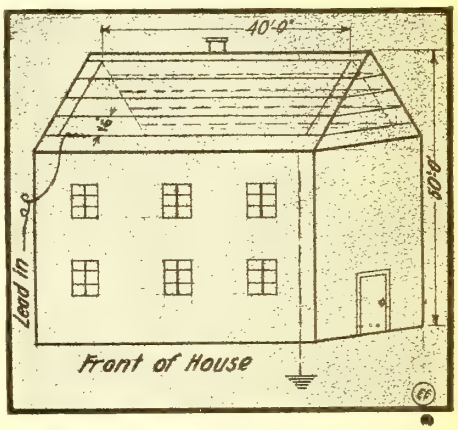
supported by a suitable frame made of brass shown in Fig. 2. The two bobbins B B are made of hard rubber as shown in Fig. 3. These bobbins are then wound with 200 feet of No. 40 B. & S. gauge copper wire on each; care should be taken that the wire is wound evenly. The iron core, Fig. 4, is now to be made from soft sheet iron No. 18 gauge. The talking head supporter is made of brass or fiber, and details are shown in Fig. 5.

The two wire reels E E¹ are easily made from two aluminum discs 2½ inches in diameter and separated by a brass washer ¾ inch in diameter. These discs are held firmly on the shaft, Fig. 6, by two ¾-inch

Photograph of Completed Telegraphone.

brass nuts. A 2-inch beveled brass gear is now placed on each shaft as shown in Fig. 1. The wire guides D D are now made, and details of their construction are shown in Fig. 7. After each separate part has been completed, assemble them as shown in Fig. 1. Two small motors 1 and 2 are connected to the beveled gears F F¹ by two small miter pinions as shown. Now procure about 200 feet of 32 gage steel piano wire and wind it on one spool. One end of the wire is now passed through the guides D D and attached to the other reel.

The two electro-magnets B B are joined in series and connected to the receiving set in substitute for the usual telephone receivers. One of the motors is now started, and if there is any message in the ether the recording coils will record every sound on the moving steel wire. To reproduce these sounds it is necessary to unreel the wire in the opposite direction. This is done by running the opposite motor and unmeshing No. 1 motor gear. Now disconnect the telegraphone from the receiving set and connect a pair of phones to the talking head, and by listening in the receivers the operator will receive every signal that has been sent. High-speed messages may thus be copied on this instrument and reproduced very slowly, so that the unprofessional operator may read the same high-speed signals slowly just by running the motor slowly, etc. The ordinary speed of the wire is 10 feet per second.



This telegraphone may be used excellently in connection with the ordinary line telephone. Telephone conversations and secret messages can be copied on this instrument just by connecting this instrument to the line wire in place of the usual receiver. It is hoped that this valuable instrument may be particularly advantageous to the experimenter who desires an instrument for recording radio signals.

The trans-Atlantic wireless stations in Germany have been heard clearly at the University of North Dakota, a distance of 4,300 miles.

SUCCESSFUL INDOOR AERIAL.

One of our readers, Raymond Schlegel, of Pittsburgh, Pa., has successfully used the form of indoor wireless aerial illustrated herewith. This arrangement consists of placing wire under the roof in the attic of the building and on both sides of the slanting roof structure. The wires are spaced about one and one-half feet apart and consist of No. 14 conductor. The highest wire in the aerial is about 50 feet above the ground. The length of the strands is 40 feet, there being nine wires in all.

They are all joined together at either end and, of course, insulators are placed in each strand. Mr. Schlegel has been able to pick up the wireless time signals from Arlington, Va., twice a day, at noon and in the evening at 10 o'clock, using a Ga-

Indoor Type Wireless Aerial. Efficient Under Wood, Slate or Tile Roofs.

lena or Silicon detector, with regular head 'phones, etc.

He states also that he can still read the time signals with this outfit with the head 'phones removed several inches from the cars. Metal-covered roofs are not as good in this case as tile covering, which obtains in this instance.

Have you voted? Do it now. See page 48.

WIRELESS ON THE MOTOR BOAT.

Now that the motor boat and yachting season is in full swing it is undoubtedly of great interest to many owners of such

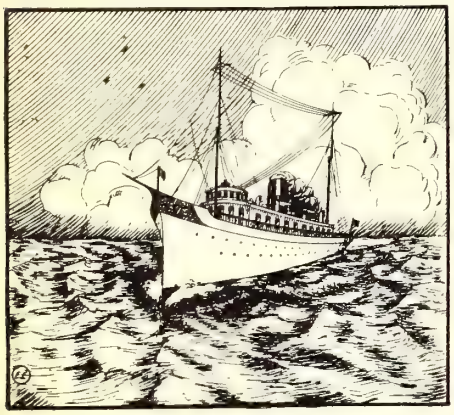


Fig. 1. Showing the Aerial on a Motor-Boat or Yacht.

craft to have a small wireless sending and receiving set on board in case of emergency, etc. It is surprising what an efficient outfit can be installed at very small cost nowadays.

The sketches and diagrams given herewith show how the set is best installed and assembled, on a hardwood or other switchboard preferably, so as to take up the minimum space possible.

Figure 1 shows the aerial arrangement for small motor boats, and it is best to have the foremast about 20 feet high at least. The small auxiliary rear mast should be nearly as high, if possible. The form of aerial shown has proven very efficient for such installations, and it may comprise four strands of phosphor-bronze cable spaced about 3 to 4 feet apart. The length of span between the spreaders will, of course, be governed by the size of the boat.

Regular antenna insulators should be used, of course, in each strand where they are fastened to the spreaders, and the lower section of the aerial should be tapered, so that all of the four or more strands are joined together to a No. 8 or larger copper conductor, passing through the lead-in tube or insulator L (see Fig. 2) placed in the roof or side wall of the cabin, as shown. It is well to place some sealing compound P over the end of the insulator L to keep water, etc., from running in during rainstorms, etc.

Regarding the radio set itself, this may be mounted exactly as the diagrams indicate and the transmitting set may comprise, for ordinary requirements, a storage battery of 6 to 8 volts, 3 to 4-inch spark coil S, Leyden jar or glass plate condenser C, tuning helix H, hot wire radiation ammeter W and throw-over aerial switch A, also key and spark gap M.

The receiving equipment may very well be selected to comprise a few high-grade and efficient instruments; such as a good-grade loose coupler B, mineral or other detector D, fixed condenser F, variable condenser K, pair of 2,000 or 3,000 ohm head phones T, together with necessary wire for connecting the various instruments.

The ground connection for such a station may be made in some cases through a No. 4 insulated copper wire G leading to the engine frame and the ground, thus established through the propeller shaft. In some cases the ground connection is made by connecting the wire G to a copper plate about 2 feet square, fastened on the outside of the hull, so that it is in thorough contact with the water.

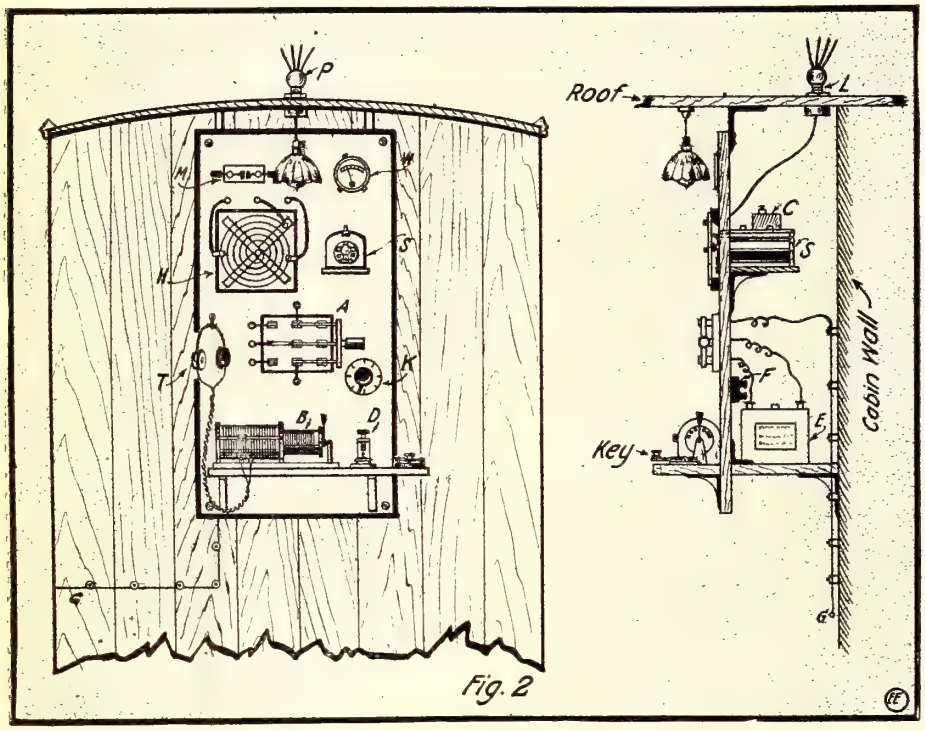

Fig. 2. Arrangement of Radio Apparatus in Cabin of Boat. Panel Style.

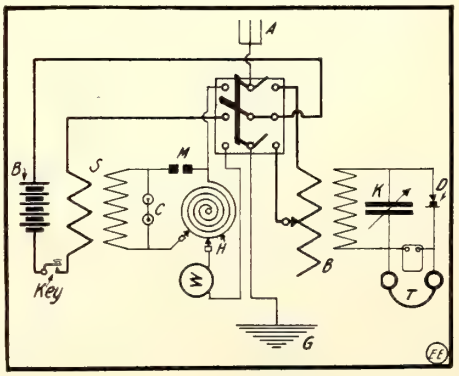

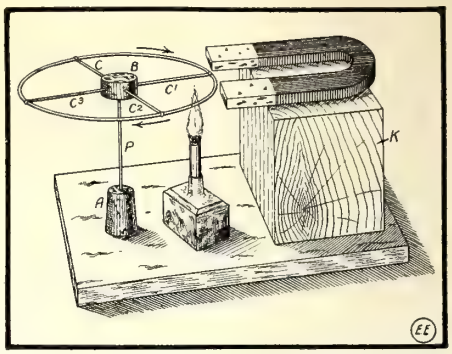

Fig. 3. Wiring Diagram of Boat Wireless Set.

At Fig. 3 is shown plainly the connections for this wireless outfit, and in transmitting the aerial switch A is closed in the proper manner and the signals are sent out, of course, in the telegraph code, which is usually now the Continental, by means of the telegraph key mounted on the front shelf of the switchboard. In tuning the receiving instruments the switches or sliders on the loose coupler are adjusted until the signals are received loudest. Also the variable condenser, if used, is moved until best results are obtained. It is best to use a regular buzzer test for adjusting the detector to its best condition. Further description is hardly necessary in this direction, as complete instructions and blue prints are invariably furnished with such an apparatus when purchased.

AN INTERESTING THERMO-ELECTRIC MOTOR.

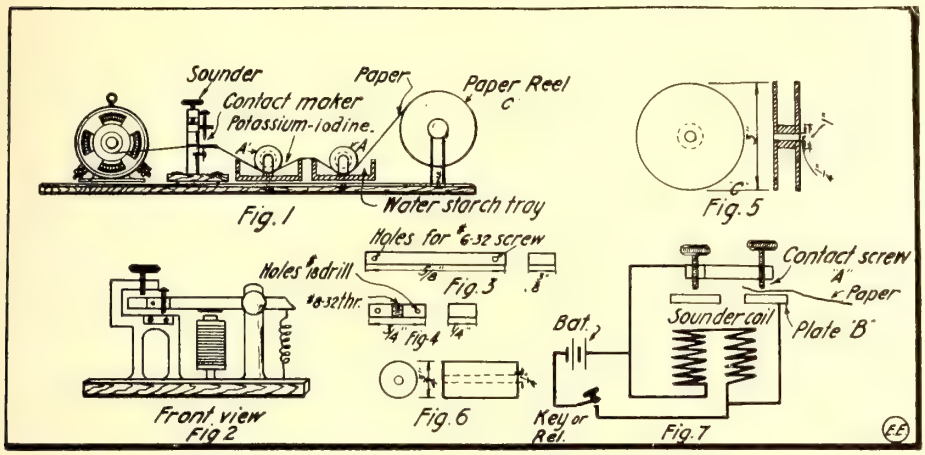
The following brief description of a very simple thermo-electric motor will make it easy to build for the ordinary experiment-

Novel Motor Works by Heat and Magnetism.

er. The rim of the wheel is made from fairly thick iron wire and held by a cork B. The spokes C, C^1, C^2, C^3, are made of copper wire. The wheel is supported by a pin P and cork A. This cork is next glued to the base. A large steel horseshoe magnet is next supported on a block of wood K, near the wheel as shown. A small alcohol lamp is now placed under the rim of the wheel. As soon as that portion of the wheel becomes hot the wheel will begin to turn slowly, the heated portion turning away from the magnet—the reason being that, while iron is attracted by a magnet at ordinary temperatures, when the temperature is increased beyond a certain limit this partially ceases to be the case. But the cooler part is still subject to magnetic attraction, and the wheel is consequently kept on turning so as to bring such cooled portions in closer proximity to the poles of the steel magnet. The rim of the wheel should be not less than 3 to 4 inches in diameter.

HOW TO AMALGAMATE ZINC.

The chief difficulty one experiences in amalgamating zinc battery rods is in rubbing the metallic mercury into the surface. This difficulty can be obviated by using the following method: At first clean thoroughly the zinc from dirt and grease by dipping the zinc into a concentrated hydrochloric acid solution. The zinc is now placed for 10 minutes in a solution of bichloride of mercury. The bichloride of mercury will decompose and metallic mercury will unite with the zinc.



(Note.—Care should be taken in handling the bichloride of mercury as this salt is very corrosive on flesh and clothes. It is also very poisonous.)

AN INKLESS TELEGRAPH RECORDER.

By Samuel Cohen.

A UNIQUE, but practical, inkless recorder can be made by anyone, which will copy "code" without using a pen or pencil.

The following material will be needed

Ingenious Telegraphic Recorder Using Neither Pen Nor Pencil.

in constructing this inkless recorder: A small battery motor, one telegraph set, four binding posts, two feet of ¼x¼-inch brass rod, two rubber rollers, two small trays, one ounce of potassium iodide, four ounces of common starch, one rheostat, one S. P. S. T. switch; three inches of ¾-inch rubber rod, 1x1-foot brass sheeting 24 gauge.

First construct the contact point shown in Fig. 4, which consists of a rubber strip ¾x¼ inch and drilled as shown. This piece is then fastened to the lever of the sounder shown in Fig. 2. Then make the contact bed, which is made of ⅜x¼-inch brass rod; dimensions are shown in Fig. 3. After it has been made, it is then fitted on the sounder bracket (Fig. 2).

Two reels are then made of No. 18 gauge brass sheeting (Fig. 5). One reel is mounted on motor, and the other reel is mounted on a brass bracket ½x⅛x4 inches.

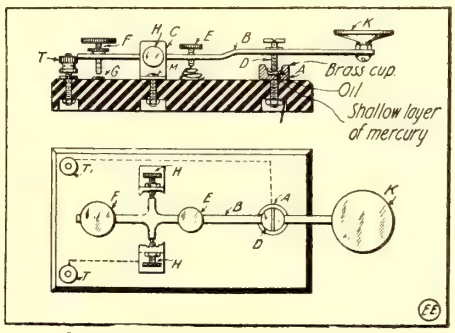
Two rubber rollers AA¹ (Fig. 1) are then made. These rollers are made of hard rubber (Fig. 6) and are mounted on brass standards 1½x½x½ inches.

Two 4x5 photograph developing trays are then mounted and clamped to the base as shown in Fig 1.

In the first tray A make a starch solution as follows: Dissolve four ounces of common potatoe starch, and in tray B dissolve four ounces of potassium iodide crystals in full tray of water.

After all the parts are made, arrange each part as shown in Fig. 1. Connect the contact point A and bed plate B as shown in Fig. 7. A rehostat and one S. P. S. T. switch is connected in series with the motor in order to regulate the speed of copying.

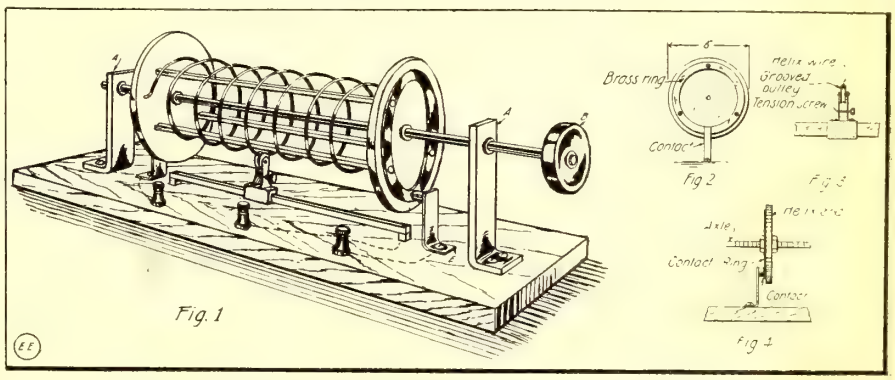
In operating this recorder properly, it is necessary that the speed of the motor is constant, or else the printing on the paper tape will not be regular.



By regulating the speed of the motor and the current through the contact point by a second rheostat telegraph code has been copied as fast as 50 words per minute. The drawings are self-explanatory.

Remember: Storage batteries have to be charged from direct current. Use a rectifier on alternating current.

A MERCURY BREAK WIRELESS KEY.



A good key for wireless transmitters is a necessity. It must be adjustable, the contacts of good size to carry heavy currents and, lastly, easily worked. The following key embodies all these good points:

The base, which is made of hard wood, may easily be procured. The size is left to the reader, that of the writer's being 6 x 3¼ x 1 in. Two holes are bored for T and T_1, the terminals. Some good, stiff brass strip is obtained and bent, as shown in figure, first drilling four holes, two on each side M_1 M_1, H and H_1; the screws

Wireless Key with Mercury Break.

M M_1 being to attach it to base and H and H_1 for pivots for the lever B. This lever, while of standard shape, is of heavier brass and longer than usual. Three holes are tapped in it for adjusting screws F, E and D. G is simply a metal rest for F. The function of F and E is apparent.

Efficient Design of Radio Helix Enabling Any Part of Coil to Be Used.

We now come to the contact device, A. This consists either of a carbon cup made from a dry-cell carbon or a brass cup, the latter is preferred. A *very* little mercury is placed in cup and covered with a little oil (olive oil will do, or even cylinder oil). The reason for the shallow mercury layer is that the tendency to "lag" will be reduced to a minimum. Then D is screwed down in the oil, so that it hardly touches the mercury. Then A is connected by a wire to T_1. For a better connection to other terminal, the spring at E may also be connected to it. K is a hard-rubber knob.

After a little practise, the adjustment may be improved so that no "lag" is detected and good satisfaction is enjoyed.

Contributed by H. C. GRAHAM.

A NEW TYPE SENDING HELIX.

A finely adjustable helix is an instrument that should be in every amateur's station, and here is one that does away with clips and loose wires.

A base is made, preferably of oak or mahogany, 24" long, 12" wide and 1" thick. Two end pieces, either round or square, should be made of the same material. If round they should be 8" in diameter, and if square, 8" by 8". In the center of each end piece a hole should be bored of ample size to admit the axle, which in turn should be threaded and provided with nuts to hold the end pieces in place.

Some No. 6 B. & S. aluminum helix wire should be procured and wound into a spiral 8" in diameter and 12" long with 1" space between turns; 3 spacing bars can be placed on frame as seen to support the wire if necessary.

Two rings are cut from sheet brass 8" O. D. by 6" I. D. by 1/16" thick. These are to be fastened on the end frame pieces by flat-headed screws passed thru countersunk holes. Get a battery bolt and file the end (the one with the screw driver notch in it) down flat, which is to be run thru the ring and end piece and fastened to the coil on the other side. The other end of the coil should be fastened to the other end piece in like manner.

The slider is made of ¼"x¼" I. D. brass tubing. Two pieces of spring brass or phosphor bronze are soldered to the top, one of which should be threaded and provided with a screw, and the other should have a hole bored in it of sufficient size to let the screw slip thru and screw into the other spring. The screw is used to regulate the grooved pulley action, as evident from Fig. 3. The slider rod is to be mounted about ¼" above the base and should be ¼" square and about 13" long.

In Fig. 1, C is a brass upright to keep the axle from slipping back and forth thru the bearings, A and A. B is a hard rubber knob fastened on the end of the axle to rotate coil.

I think the drawings will explain the rest, and the dimensions may vary to suit each builder.

By J. H. ALDEN.

Spectacular Discharges and Large Tesla Coils

To the uninitiated in electrical science there is probably no more entrancing and awe-inspiring effect to be seen than the spectacular display produced by the Tesla transformer. There are many acts traveling over the various theatre circuits which make use of the Tesla high frequency apparatus, and herein we will describe briefly how to construct one of these large 36" spark Tesla coils, together with necessary exciting transformer, auxiliary condenser and also spark gap.

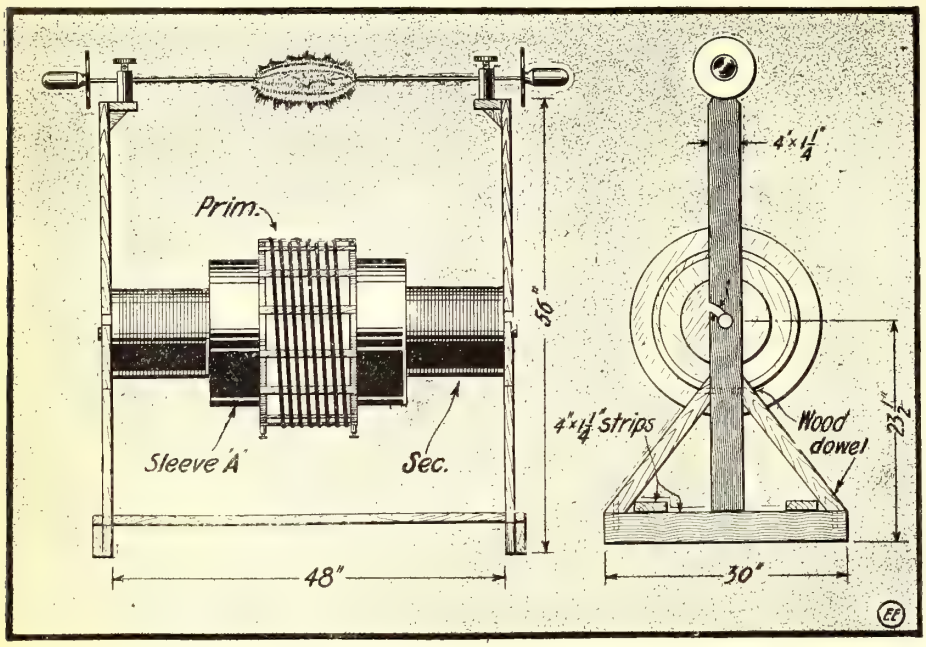


Fig. 2A. Appearance of Complete Tesla Coil for Use on 1 K. W. Transformer.

Referring to Fig. 1, the complete closed core type high voltage 1 kilowatt transformer is shown at A. As seen, the secondary and primary coils are wound each on one of the longer legs of the sheet iron core. The completed transformer may very well be mounted in a metal or lead lined wooden case, as shown at B, which is afterward filled with transit oil. The transformer is mounted on a couple of wood blocks, as indicated, placed inside the case.

Referring to details on this transformer, which is designed for operation on 110 volt, 60 cycle A. C. circuit, at a current of 9 to 10 amperes maximum, the dimensions and method of assembling the alternate layers of sheet iron strips are shown at C, Fig. 1. As seen, the individual strips, such as Nos. 1, 2, 3, 4, are staggered or lapped over the joints between the strips on the layer under it, as indicated by the dotted lines. In this way a solid core is easily built up and at either end suitable clamps made from a couple of pieces of iron or brass, with a couple of bolts, should be used to clamp it firmly together.

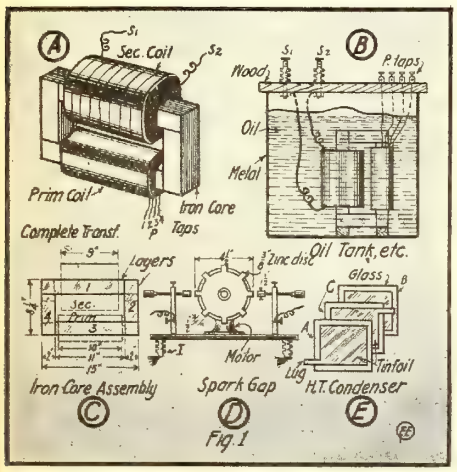

Fig. 1. Details of Step-Up Exciting Transformer, Condenser, and Spark Gap.

The transformer coils are best wound on wooden forms. The primary is 10" long and has on it 12 pounds, or 344 turns, of No. 10 B. & S. D. C. C. wire, with taps from the 250, 300, 344, and 1st turn for secondary voltage adjustment. Wrap several layers oiled linen around the primary core before slipping on the coil. Details on winding are given in any handbook on transformers.

The secondary comprises 11 pounds, or 50,000 turns, of No. 33 B. & S. enameled magnet wire, wound in 24 wax-impregnated pies or sections, each ¼" thick. Secondary then gives about 20,000 volts, with 250 primary turns in circuit. An adjustable choke coil like the primary in construction helps out the control nicely. The secondary core leg is to have 10-12 layers of oiled linen on it before the secondary pies are slipped over it.

The spark gap used for this 1 kilowatt high frequency generating outfit is probably best made of the rotary type, as shown at D, Fig. 1. This gap is composed of a zinc disc, about 4½" in diameter, having 8 to 10 projecting plugs cut on same as shown, to provide sparking points, as the disc is rotated by a suitable motor. This may be an ordinary fan motor. Two stationary spark electrodes are provided, as indicated, and the whole arrangement is best mounted on a marble or glass base. A piece of hard wood thoroughly boiled in hot wax may be utilized for the base.

Regarding the high voltage glass plate condenser for this outfit its arrangement is shown at E, Fig. 1. About .042 M. F. capacity is required in this condenser when the transformer delivers 20,000 volts, 60 cycle A. C., at the secondary terminals. If ordinary glass is used ⅛" thick, about 46 such plates measuring 12x14" are necessary, both sides of the plates being coated with heavy tinfoil 8x10", cut with a projecting connection lug as shown at E. When the condenser has been prepared it may be mounted in a cabinet suitably built and then filled with parafine or transit oil. The glass plates are placed one on top of the other in the final assembly, and there is only, of course, 1 tinfoil leaf between each plate. Every other tinfoil leaf connects to a common terminal, and in this way all the glass plates connected are charged and discharged when in circuit.

The dimensions for the large Tesla coil to be used with this outfit, capable of producing 30 to 36" high frequency sparks when all of the apparatus is properly tuned and adjusted, are given at Figs. 2 and 2A. This special large size, extra high voltage, high frequency air core transformer, is built at small cost and consists of a primary and secondary coil as usual, as well as an insulating sleeve A, ¾" thick, made of shellacked paper or oiled linen.

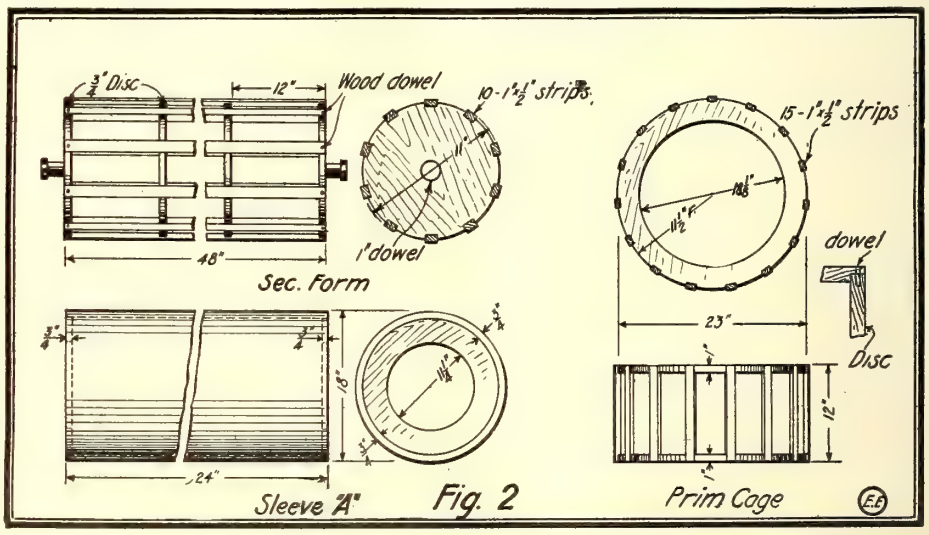

Fig. 2. Details of Large 36-Inch Spark Tesla Coil Parts.

The wooden framework for supporting the coils is indicated quite clearly in the drawing, and all of the wood parts are best boiled in hot wax. No metal parts, excepting the wire on the coils, should be used in constructing this transformer. The wood joints are readily held together securely by drilling ¼" holes and driving in same wooden dowel pins.

The secondary cage is made up of four

wood discs with 10 wood strips doweled fast to them as shown. The primary form is made in the form of a cage also, as indicated, of two wood rings and 15 wood strips, also held in place by wood dowels.

The primary of this large Telsa coil can be wound with 10 turns of No. 4 B. & S. bare copper, brass or aluminum wire spaced 1" between turns and the ends of the coil brought out to two binding posts. A substantial helix clip should be provided for one terminal of the primary circuit for adjustment. The secondary coil is wound with one layer No. 24 B. & S. enameled magnet wire, and each turn should be spaced apart the thickness of the wire by winding on a lathe, etc. Before winding the secondary coil the wooden cage may be covered with several layers of stiff paper or a layer of Bristol board. The layers of wire should be well shellacked.

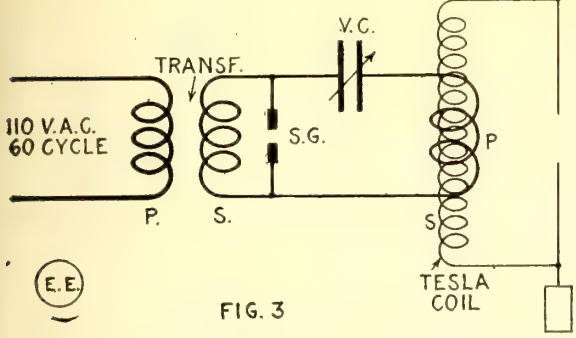

FIG. 3

Hook-Up of Large Tesla Coil and Exciting Transformer.

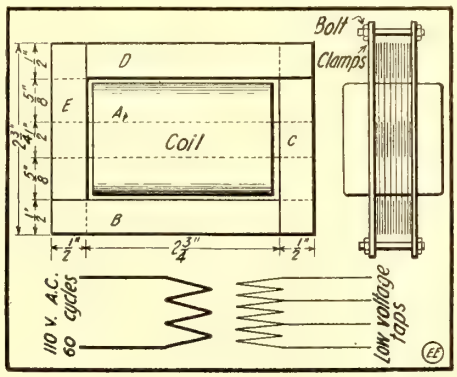
The connections for the complete outfit are shown at Fig. 3, where V. C. is the high voltage condenser arranged to be adjustable, and S. G. is the rotary spark gap. P. & S. are the primaries and secondaries, respectively, of the transformers. Tune the set for best results by altering the condenser plates on multiple and gap speed, the exciting transformer, and the Tesla primary turns in circuit. Use No. 6 wire or, better, copper ribbon for the high frequency connections.

FLUORESCENT WRITING.

If we dissolve some sulphate of quinine in water and then draw a design or write some motto or sentence on a piece of white paper with the solution and allow it to dry the drawing or design will be absolutely invisible. But if this same piece of paper be illuminated by the light of a Geissler or vacuum tube then the design or writing will at once appear as if written or drawn with a beautiful blue ink.

MARKING TOOLS WITH ACID.

The *American Machinist* recommends the following etching fluid for marking tools: Mix one part of muriatic acid, one of nitric and four parts of water. The tool is coated with wax and the design is then scratched in.



CONSTRUCTING A BELL-RINGING TRANSFORMER.

A small transformer, that can be used to operate bells, motors, etc., when supplied with 110 volts A. C., can be made very cheaply and saves the battery bill.

First construct the core, which consists of sheet iron strips. Cut up a pile of strips ½x3¼ inches for the middle leg A, and ¾-inch high when compressed. In a like manner cut up a pile with the dimensions ½x 3¾x¾ inches high, for two outside legs B and D. For the parts E and C cut up one pile only, ½x2¾x¾ inches high. The middle core A should be wound at first with five or six layers of heavy paper, and place over this a layer of friction tape. Now wind on one ounce of No. 34 enameled wire and wind it on the central portion as evenly as possible. The primary winding is then covered with several alternate layers of tape and shellacked paper.

The secondary winding consists of three sizes of insulated magnet wire, first, 100 turns of No. 22; second, 100 turns of No. 2, and third, 150 turns of No. 26. The ends of each winding are connected together, the end of the first to the beginning of the second, etc. This arrangement allows a final choice of three secondary voltages. The whole core should be arranged as shown in drawing. The core is held together by two clamps, one on each end. These clamps are made of strips of iron ⅛-inch thick, and are cut ½x3½ inches, four pieces being needed for the two clamps. One-eighth inch from each end a 3-16-inch hole is drilled. The core should be clamped in a vise and tightened up by the bolts on each end.

The transformer thus made may now be mounted in a suitable metal box filled with wax, and proper connections made as shown in diagram.

How a Bell-Ringing A. C. Transformer Is Made.

THE "GEAR" ROTARY SPARK GAP.

By S. Kruse.

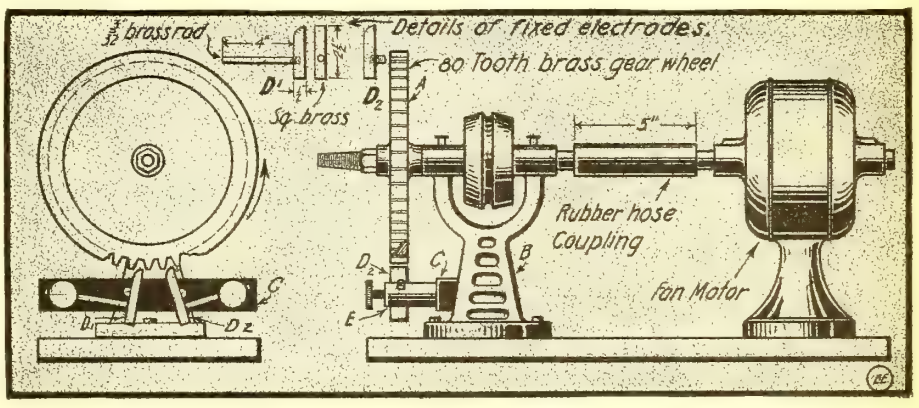
The McCreary-Moore gear-gap is not as well known as its merits deserve. In the original design developed by Robert Moore an 80-tooth 16-pitch (5-inch diameter) brass gear, from which every second tooth has been removed, is mounted on the shaft of a "polishing head" B. The fiber or oak bar C carries two ½-inch brass rods or two large binding posts bushed up with washers, which in turn support the fixed electrodes of the form D.

It is of the utmost importance that the fixed electrodes be of the form indicated and that they be mounted on the frame and not on the base, to prevent vibration from the motor causing the electrodes to move.

The gear must be very carefully trued by mounting it on a shaft and then laying the shaft on a pair of straight-edges (rulers, saw-backs, etc.), and filing the rim of the heavy side till the gear will stay in any position.

The solid construction, good balance and comparatively low speed insure a wheel that is quiet and true-running to a hairline, while the shape of the parts gives a slow approach, yet a very sharp break.

The result is a tone equaled only by a 500-cycle synchronous gap.



If a lower note is desired a Marconi tone may be obtained by removing 60 teeth and leaving 20. If preferred, a bicycle sprocket may be used, but it is hard to get perfect running unless a metal bushing is used.

The gap *must* be set as close as it will run—never over 1-20 inch—and will operate on as little as 100 watts. If more than 300 watts are employed a series-fixed or quenched gap may be employed to advantage.

When used as shown, direct-connected to a 12-inch induction fan motor, this gap is absolutely trouble-proof. A 60-cycle motor of this type runs at 1,750 r.p.m. on light loads, which gives (about) 1,200 and 600 sparks for the 40-tooth and 20-tooth wheels.

Where there is little "QRM" the 600 rate is better, but with much interference the high tone "cuts through" better.

In conclusion I will say that the gear-gap is universal in this region and that we have ranges which, for the power used, are second to none. My call is 9 LQ.

Unique Spark Gap Made from Gear Wheel Having Alternate Teeth Removed.

SUN SPOTS UPSET WIRELESS.

Unusual sun spot activity was reported recently by astronomers at Christian Brothers College, St. Louis, Mo. The wireless instruments at the college were greatly disturbed, and this is attributed to the sun spots. Nine spots were visible.

Litigation between the Marconi Wireless Telegraph Co. and the National Electric Signaling Co. has been settled by a license agreement by which the Marconi company secures the use of 171 Fessenden patents and in return grants the use of two basic tuning patents of Marconi and Lodge.

Uncle Sam's newest dreadnought is to be driven by powerful electric motors. Steam turbines drive the dynamos.

WRINKLES — RECIPES — FORMULAS

Edited by S. GERNSBACK

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA No. 10.
Paints.

Proportions of Colors for Ordinary Paints:

White—100 parts of *White Lead.*

Black—100 parts of *Lampblack.*

Green—25 parts of *White Lead* and 75 parts of *Verdigris.*

Stone—99 parts of *White Lead* and 1 part *Burnt Umber.*

Lead—98 parts of *White Lead* and 2 parts of *Lampblack.*

Red—50 parts of *Red Lead* and 50 parts of *Red Ocher.*

Chocolate—4 parts of *Lampblack* and 95 parts of *Spanish Brown.*

Add the required quantity of *Raw Linseed Oil, Boiled Linseed Oil, Turpentine* and *Drier.*

For 20 lb. of paint take 2 lb. of *Raw Linseed Oil,* 2 lb. of *Boiled Linseed Oil,* ½ lb. of *Turpentine,* 1-10 lb. of *Drier.*

The proportions given must only be taken as an approximate guide when the materials are of good quality.

Anti-Corrosive Paint.—Take equal parts (by weight) of *Whiting* and *White Lead,* with half the quantity of *Fine Sand* or *Gravel,* with a sufficient quantity of *Color.* This paint can be used as a water color, but it is more durable to dry it in cakes or powder after mixing, and then use it as an oil paint by grinding it again in linseed oil. The proportions are: 12 parts of *Raw Linseed Oil;* 1 part *Boiled Linseed Oil* and 3 parts of *Sulphate of Lime* well mixed; 1 gal. of this prepared oil is used to 7 lb. of the powder.

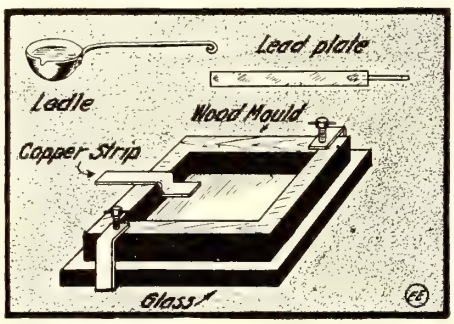
Luminous Paint.—Mix together 40 parts of *Copal Varnish* (containing neither lead nor manganese, which would destroy the phosphorescence); 6 parts of prepared *Barium Sulphate;* 6 parts of prepared *Calcium Carbonate;* 12 parts of prepared *White Zinc Sulphite;* 36 parts of good *Luminous Calcium Sulphite* in a proper vessel to an emulsion and then grind it very fine in a color mill.

Phosphorescent Paint.—Heat *Strontium Thisulphate* for 15 minutes over a good Bunsen gas lamp, and then for 5 minutes over a blast lamp. Mix with pure *Melted Paraffin* for use as a paint for clock dials, etc., and expose for a time to sunlight.

Stencil Paint.—Take *Shellac,* 2 oz.; *Borax,* 2 oz.; *Water,* 25 oz.; *Gum Arabic,* 2 oz.; *Lampblack,* sufficient quantity. Boil the borax and shellac in water till they are dissolved; when the solution has become cold, complete 25 oz. with water and add lampblack enough to bring the preparation to a suitable consistence.

Innoxious Color for Painting Toys.—Mix 6 parts of *White Fine Chalk,* 3 parts of *Calcined Magnesia* (thoroughly calcined). Add a few drops of indigo solution. Oil, turpentine, driers as for any other paint.

White Paint for Metallic Surfaces.—Oil paints used on metallic surfaces exposed to heat frequently turn yellow. If, instead of oil, *Sodium Silicate* be used, no change of color will be noticed.



Marine Paint.—For metals in salt water: 44 parts of *Red Lead,* 24 parts of *Quicksilver,* 5½ parts of *Thick Turpentine.* Mix to proper consistency with boiled linseed oil. Grind the turpentine and quicksilver together. Then grind this mixture with the red lead and add the linseed oil. Use as little oil as is necessary to make the paint lay on well. To make the Marine Paint adhere firmly, use first a coat of *Oxide of Iron.*

A REMARKABLE PRIMARY BATTERY.

The primary cell with which we are all familiar has one bad feature, viz., polarization. To overcome this trouble, due to using metal electrodes such as zinc, which allow the electrolyte solution to carry zinc salts to the surface of the opposite electrode, of copper, say, one of the most ingenious improvements in a long time has been made by E. Bellini.

His method is quite radical in primary battery design, and instead of employing zinc for the negative electrode he has utilized a cast-lead plate having a slight amount of mercury in it.

In Mr. Bellini's battery the negative electrode is formed of an amalgam of lead, formed by pouring mercury into the molten lead. A suitable proportion is to take one part by weight of mercury and nine parts by weight of lead. The positive electrode is a carbon sheet. The electrolyte is a mixture of sulphuric and nitric acids. A suitable proportion for the solution has been found by mixing a litre of water with 80 cubic cm. of sulphuric acid

Showing Mould for Casting New Mercury and Lead Battery Plates.

of 66 deg. Baumé and 120 cubic cm. of nitric acid of 36 deg. Baumé. The E. M. F. of this battery will be found to be 1.25 volts. During the working of the battery a white, flocculent and heavy substance falls from the negative electrode to the bottom of the cell. This substance is formed of lead sulphate, mercurous sulphate and of little globules of metallic mercury. Gas is given off from the positive electrode, and this is found to consist of the products of decomposition of nitric acid.

In the illustration is depicted a simple scheme for casting these special lead amalgam plates. A wood block is mortised out as seen and is backed up by a slate or other smooth plate. Clamps or weights hold the two together. A little fire clay or putty may be placed around the outside seam of the slate and wood. For connection a copper strip is bent as shown and placed in the mold so as to be cast in the plate. The molten lead amalgam is poured into the mould and soon becomes solidified. The slight amount of mercury is added to the hot lead before pouring. The plate can be about ⅛ to $\frac{3}{16}$ inch thick.

The battery used for the author's test in finding the rate of discharge was formed of four positive plates, placed alternately with three negative or lead amalgam plates. The total active surface of negative electrode was 900 square cm., and of the positive 1,230 square cm. The mean distance between the electrodes was 2 cm. The total amount of electrolyte was 2.6 litres. The internal resistance was 0.022 ohm for a rate of discharge of 5 amperes. The capacity was found to be 112.5 ampere-hours. At the end of the 24 hours there was added 450 cubic cm. of water, 96 cubic cm. of sulphuric acid of 66 degrees B, and 192 cubic cm. of nitric acid of 36 deg. B.; the test was then continued for a further period of 14 hours. The capacity was 63 ampere-hours. The same amount of electrolyte was then added again, and the battery was then discharged for 27 hours, with an interval of rest of 11 hours in the middle of the test, the capacity being in the last case 115 ampere-hours.

The consumption of the amalgam on open circuit is very small, and to all intents and purposes nil, provided the surface of the electrode is clean and free from any foreign substance which might give rise to local couples. The consumption of the amalgam on closed circuit is about 5 grammes per ampere-hour. This battery seems to have considerable merit indeed.

BOOK REVIEW.

"Oxy-Acetylene Welding and Cutting." By Calvin F. Swingle, M.E. 200 pages. 76 illustrations. Size 4½x6¾ inches. Published by Frederick J. Drake & Co., Chicago, Ill. $1.00. Cloth.

A timely treatise written in easily understood fashion on the operation and care of acetylene generating plants; also the removal of carbon by the oxygen process. The illustrations are very clear, making the matter easily interpreted to the layman. The subject starts off with welding, oxygen and its properties, acetylene and acetylene generators, etc.

Practical instructions are cited throughout the book in regard to the best way to burn steel beams in half, cutting off pipes, boilers, and other details of interest to the oxy-acetylene operator and lay reader alike.

"Drake's Telephone Handbook." By David Penn Moreton, B.S., E.E., Associate Professor of Electrical Engineering, Armour Institute of Technology. Pocket size, 4½x7 inches. Cloth covers. 285 pages, 161 illustrations. Price, $1. Frederick J. Drake & Co., Chicago, Ill.

A new book on practical telephone matters by Professor Moreton, and written in his easily understood style, suitably illustrated. The first part of the book takes up the fundamentals of electricity rather briefly, but this is made up for by the excellent and complete digest of up-to-date telephone systems. One chapter deals with the physics of sound as related to telephone matters, and then follows magnet systems, common battery systems, the construction of telephone lines, with span, tables, etc., while the book finishes with a complete index to all ordinary telephone line and instrument troubles.

The section on common battery systems is modern and covers the Bell and Western Electric circuits, which are clearly explained, so that anyone can soon grasp the principles involved in making a connection through a central battery exchange. Moreover, all of the standard apparatus is mentioned in diagrams, such as P. B. X. exchanges, with W. E. Co. equipment, including type number, etc., as 10 ohm 118-A.P. relays, 8-P retard coil, 87-A relay, et cetera. Undoubtedly this book, especially at the price, will have a large sale among those interested in the actual working details of modern telephone systems.

The Fessenden Radio Station at Brooklyn, N. Y.

The National Electric Signaling Co., exploiting the wireless patents and inventions of Prof. Reginald A. Fessenden, formerly special scientist in wireless research for the United States Government, and now the inventor of the new submarine signal, has a very fine radio plant at Brooklyn.

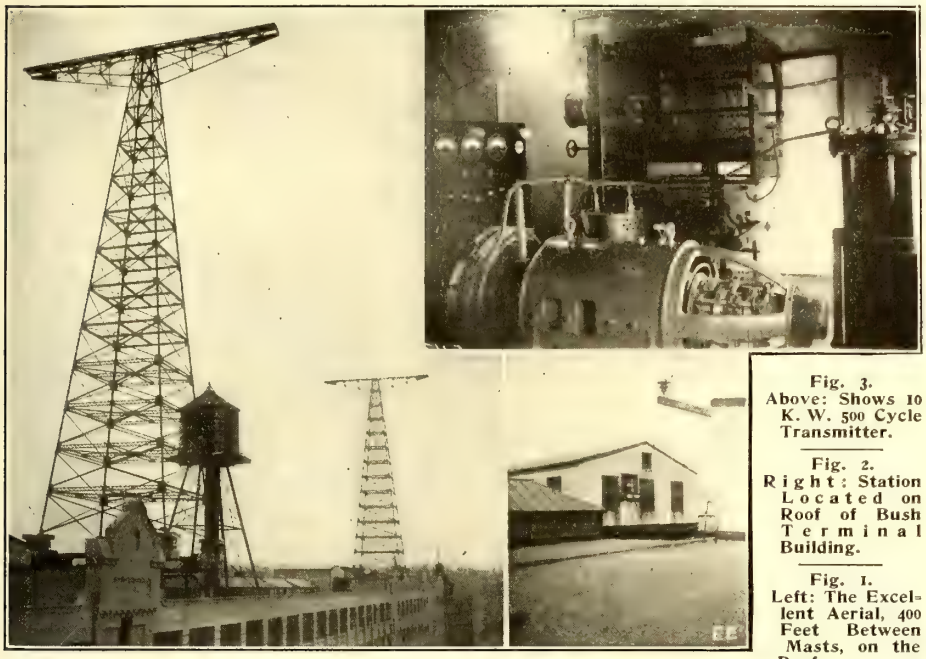


Fig. 3. Above: Shows 10 K. W. 500 Cycle Transmitter.

Fig. 2. Right: Station Located on Roof of Bush Terminal Building.

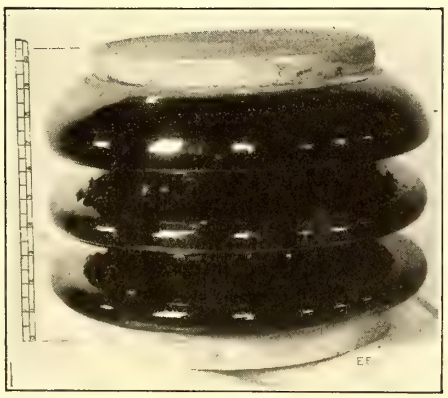
Fig. 1. Left: The Excellent Aerial, 400 Feet Between Masts, on the Roof.

The photographs here shown illustrate the mighty steel aerial towers, also station and apparatus of its plant located at the Bush Terminal, Brooklyn, N. Y. On the roof of the six-story concrete building, in which the plant is located, two gigantic latticed steel masts are erected, which are seen in the photograph.

These towers (Fig. 1) are substantially constructed to withstand a heavy gale. The aerial span is about 400 feet and the height of each tower is 150 feet. The towers are insulated from their supporting surface on the roof by a concrete foundation and conical porcelain foot insulators about 2 feet high. The cross-arms, or spreaders, at the top of the towers, are about 40 feet long and support 15 phosphor bronze aerial cables.

The lead-in (Fig. 2) is brought to a lightning grounding switch outside of the station and another wire is led into the station, where it is connected to a regular antenna switch.

The station has a high frequency alternator, which is capable of delivering an alternating current with a frequency of 200,000 cycles per second. This high frequency alternator is driven at an enormous velocity, the speed often being as high at 30,000 revolutions per minute. It is driven by a De Laval steam turbine, in which the shaft runs at 25,000 to 30,000 R. P. M. The alternator delivers an output of 2 K. W.



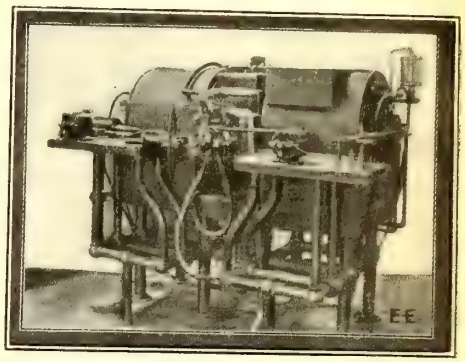
The regular 10 K. W. transmitting apparatus is shown in photograph (Fig. 3). This generator is seen in the foreground. The condensers are located at the extreme right in the photo and are of the compressed air type. The oscillation transformer is located on the rear of the transmitting panel and is discerned at the center of the photograph.

The inductance of the oscillation transformer is regulated by means of a handle in front of the panel below one of the meters as perceived. Remarkable results have been obtained with this 500 cycle set. Signals have been transmitted in daylight to Galveston, Tex., without any trouble, which is quite remarkable from the standpoint of efficiency.

The receiving set consists of the standard Fessenden type heterodyne receiver, operating upon the "beat" principle, thus realizing an amplification value of considerable power. Messages are daily copied from Nauen, Germany; Honolulu, etc. Illustrations through courtesy of Mr. Kroger, chief engineer.

MASSIVE INSULATORS FOR RADIO TOWERS.

The object of the extremely large porcelain supporting insulator here shown is to provide an insulated base for support and insulation of large electric conductors, and especially for currents at ultra-high voltages.



Massive Radio Mast Foot Insulator.

The insulators are manufactured by the wet process method, and stand 10½" high and are provided with corrugations or petticoats to increase the creepage distance and give a sheltered or dry surface under rain or storm conditions, the top and bottom of the insulator being provided with metal castings for mounting purposes. The total weight of the individual insulator is 120 lbs., including the metal parts. This design of insulator is capable of supporting a load of 500,000 lbs. and has an ultimate strength of 1,150,000 lbs.

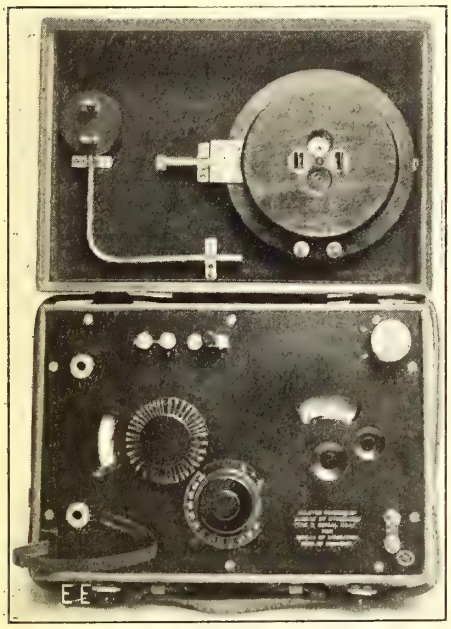
This class of insulator is being used by the United States Government at its wireless stations at Panama, Balboa, San Diego, Cal., Honolulu in the Hawaiian Islands, Tutuila in the Samoan group, Guam and still another at Manila in the Philippines.

OVER 4,000 MILES BY WIRELESS ARC.

The Poulsen arc rated at 100 kilowatts and the long-distance work accomplished by its use in signaling from San Francisco to Honolulu and from Tuckerton to Honolulu (a distance of 4,330 miles) was featured in an excellent paper by L. C. Fuller, of the Federal Telegraph Co., at the April meeting of the American Institute of Electrical Engineers, New York.

Type of 100 K. W. Poulsen Arc Used to Signal 4,330 Miles.

It was a joint meeting of the American Institute of Electrical Engineers and the Institute of Radio Engineers. The Austin radio-transmission formula was checked in these tests by Mr. Fuller and fairly well substantiated for distances up to 4,330 miles, and this work should indeed be of great value to the radio profession engaged in designing long-distance apparatus. Wave lengths up to 11,000 meters were used. At 10,000 meters, using the 100-K.W. arc at Tuckerton, N. J., a daylight current of 5½ micro-amperes (5½-millionths of an ampere) was received The tikker was employed. The Goldschmidt alternator and the arc appear to give equally good results. Prof. Zenneck, of Germany, took part in the discussion, as well as several others of prominence in radio circles.



INSTITUTE OF RADIO ENGINEERS MEETING.

The monthly meeting of the Institute was held on Wednesday evening, May 5, in Fayerweather Hall, Columbia University, New York city.

A paper by Mr. Benjamin Liebowitz was presented on "The Pupin Theory of Asymmetrical Rotors in Unidirectional Fields, with Special Reference to the Theory of the Goldschmidt Alternator." This paper dealt with the theory of the Goldschmidt alternator in particular, as developed by Prof. Pupin and contains some interesting conclusions.

THE KOLSTER RADIO DECREMETER.

In radiotelegraphic circuits, the decay of the current surges is very important. Technically, it is known as the logarithmic

New Kolster Radio Decremeter.

decrement. This factor is stipulated by the United States statutes governing radio stations to be of 2/10 or less in magnitude. To furnish a quick and easily manipulated instrument for the purpose, the instrument shown was perfected by F. A. Kolster, of the Bureau of Standards.

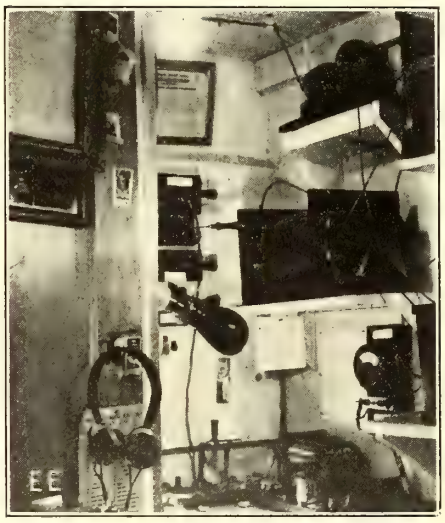
It comprises interlocking condenser knobs, buzzer, hot wire meter, extra loading condenser, and exploring inductance coils, which latter may be seen resting in the lid of the cabinet. This instrument permits of all necessary wave measurements and is widely employed by the Government radio inspectors.

H. A. MERKEL HAS RADIO STATION.

H. A. Merkel, a telegraph operator at Lyons Station, Pa., and living south of Fleetwood, is spending his spare time on his wireless telegraph. He has made extensive improvements to his apparatus, his aerial with his old arrangement having had considerable difficulty to read ships at sea and land stations over 600 miles away.

Mr. Merkel has now erected a mast 85 feet high and has lengthened the aerial to 130 feet, whereby he expects to have results that will liberally pay for his extra outlay of work and money. It has attracted hundreds of people in this vicinity, and the visitors find Mr. Merkel always ready to give them a thoro demonstration of his wireless.

WIRELESS IN THE POLICE BARRACKS.



By Frank C. Perkins.

The accompanying illustration shows a novel wireless equipment in the Pennsylvania State Police Barracks at Pottsville, Pa. The sending apparatus consists of a Blitzen transformer, a condenser, oscillation transformer, rotary gap and hot wire ammeter arranged as shown in the photograph.

The receiving set includes what is termed a Radion receiving set, with loose coupler or transformer, Universal detector using Ferron crystal, fixed condenser, rotary variable condenser and two double telephone head sets with all wiring, including the Blitzen duplex loading coil and switch having a range of wave lengths covering all stations in the United States, all mounted on a mahogany base.

It may be stated that the aerial consists of four wires suspended in the air 75 to 100 feet, composed of phosphor bronze cable 50 feet long on top of the barracks, which is a three-story building. The lead wires from the aerial comes in separate to four double-throw single-pole switches. With proper manipulation of the switches the operator is able to receive and send on any desired wave length, the aerial being bridged at one end with wires one and two connected together. Two and three aerial leads connected by a single pole switch near aerial leads to instruments make it possible to use only two wires for receiving or four, or making the entire length of the wires one single wire by bridging the two other wires three and four at other end of aerial.

It is of interest to note that the ground wire is connected to the city water mains, besides several copper wires laid in the earth several feet deep under the aerial and all connected together. The joints are soldered throughout the entire plant. From this wireless plant all the commercial stations have been heard within a radius of several hundred miles, including Key West and the station at Guantanamo, Cuba, besides all the stations using from 175 meters up. This station is rated at one kilo-

Wireless Used by Police Department, at Pottsville, Pa.

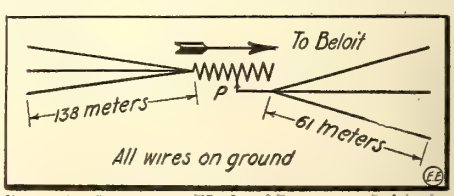
watt and has a sending radius of about 75 to 100 miles. The operator is Cotesworth M. Jackson, of the Pennsylvania State police force.

EFFECT OF THE EARTH IN RADIO TELEGRAPHY?

Prof. J. A. Fleming delivered an address on "The Function of the Earth in Radio Telegraphy" before the Wireless Society of London, recently.

It was an undoubted fact, he said, that the nature of the earth's surface exerted a most important effect on wireless transmission over it. In certain districts there was quite abnormal wave attenuation as, for instance, north and northeast of Newport, R. I. (U. S. A.), in the district where Dr. Austin's experiments were carried out between Brant Rock and the Cruiser "Birmingham."

Assuming standard physical properties, the depth of the "current skin" in the copper was about ¼ mm., but in iron it was only 1/50 mm., owing to the high permeability of this metal. By means of striking cymometer experiments, Prof. Fleming showed that while insulating coverings did not affect the damping produced by the magnetic properties of iron, galvanizing provided a skin of zinc thick enough to carry the high-frequency current without permitting the latter to reach the iron core. Galvanized iron wire was, therefore, permissible for aerials and for earth connections so long as the galvanizing remained continuous and uncorroded.



The materials of the earth's crust were conducting dielectrics, and the problem of the current penetration was complicated by the fact that conducted current and dielectric current had both to be taken into account. The conductivity of all dielectric materials, even if imperfect dielectrics, was much greater for alternating than for direct currents and was vastly greater still when carrying currents of radio-telegraphic frequency. There was, he said, a fertile field for research in measuring the conductivity and dielectric constants of the sea water and earth crust materials at radio-telegraphic frequencies, and particularly valuable results might be expected from really large scale experiments say, with huge electrodes one-quarter mile or so apart, which would give reliable averages for various kinds of soil under various conditions.

Prof. Fleming showed mathematically that refraction of electrostatic fields between air and earth or water produced a considerable horizontal component near the surface, thus producing a periodic displacement or wave in the earth's crust. To this prenomenon the speaker attributed the possibility of reception of time signals on such unorthodox aerials as bedsteads, bicycles and dustbins.

Though much yet remained to be learned, it was definitely established that good conductors prevented deep current penetration; that penetration and attenuation occurred apart from mere weakening by diffusion; that attenuation was greater for short than for long waves, and reached a maximum at certain values of permeability, resistance and dielectric constant; and that the curvature of the earth weakened the true space wave. At 3,000 to 6,000 miles, most of the received effect was probably due to bending by ionic refraction. Long-distance reception was complicated by many factors, and our earth was probably unique in being the only planet on which long-distance radio-telegraphy was possible.

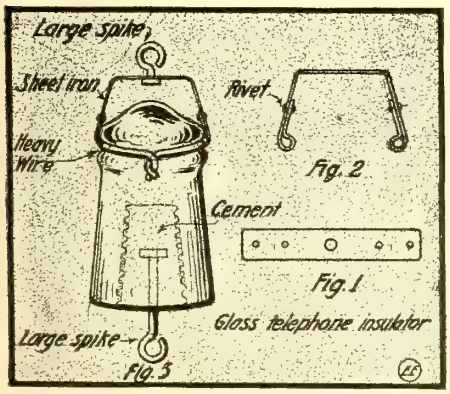
RADIO ANTENNAE ON GROUND.

A number of interesting tests on radio antennæ, composed of magnet wire resting on the ground are described in the *Elec-*

Arrangement of Ground Aerial.

trical World for March 20, 1915; Stations 600 kilometers away were clearly read.

As a result of the experiments several facts stand out more or less clearly. In the first place, so far as we know, this is the first time in this country that electric waves have been successfully received over



commercial distances by using a single bare wire placed directly on the ground, say the authors. Further, it is apparent that a somewhat symmetrical multiple earth-wire system may be used for receiving in practical radio communication, without necessitating any increase in sending power over that employed when utilizing ordinary elevated antennae. It is also evident that such single or multiple earth-wire systems possess a directive effect, and that the elements which extend away from the transmitting station are the most important in this respect.

When used as an absorber, insulation of the wires apparently plays a very minor part. The best system evolved is shown in diagram; the multiple wires being joined to a loose coupler primary, P, situated 61 meters from the end, pointing toward Beloit, where the transmitter was located.

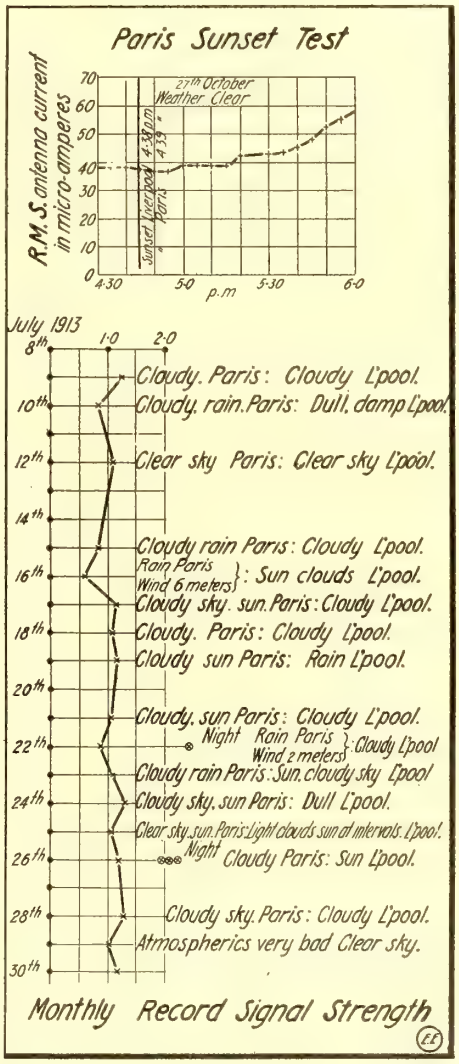
Magnetic coils for high frequency or wireless circuits contain no iron, as the current changes from positive to negative so fast, the iron cannot magnetize and demagnetize fast enough, giving rise to high hysteresis loss, as it is called. As high frequency alternators work at 100,000 cycles with iron cores, it is peculiar that inductance coils cannot have iron cores, and thus raise their efficiency.

HOW TO MAKE STRAIN INSULATORS.

Very good insulators for wireless aerials, etc., may be easily made from ordinary telephone insulators. First select good, sound insulators, and for each cut a sheet metal strap about one-inch wide and long enough so that after it is shaped (like shown in Fig. 2) the loops at each end will fit into the wire channel of the insulator. The loops at the end are first riveted, and then a hole is drilled in the center and a large spike inserted which is formed into a hook as shown. Hook the loops in the wire channel of the insulator and draw a heavy wire through the loops and around the insulator, then twist the ends quite tight. Make another hook from a large spike and with some cement imbed the head end of the spike in the hollow end of the insulator, as shown in Fig. 3. I am using these insulators in my wireless aerial with very good results. They will

Strain Insulator Made of Glass and Cement.

stand considerable strain and quite high voltage without breaking, besides being very cheaply constructed.



Contributed by
FRANK HAVERLAND, JR.

Do you know that "movie" machines consume very often as much as four to five horsepower?

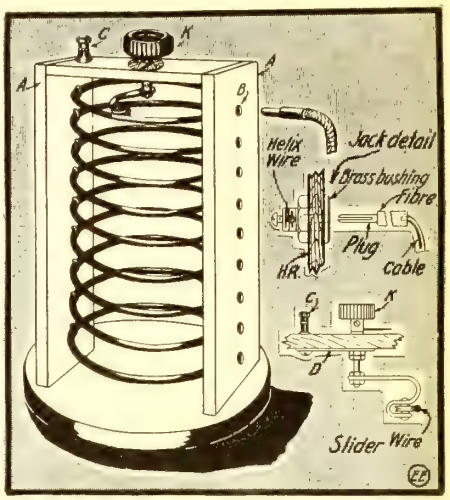
VARIATION OF STRENGTH OF RADIO SIGNALS.

In a paper by Prof. E. W. Marchant, D.Sc., in *The Electrician*, London, for Feb. 12, 1915, much interesting data, together with curves, is given on the conditions affecting the variations in strength of wireless signals, covering a considerable period.

One of the earliest observations in connection with wireless telegraphy was that it was possible to transmit over much longer distances by night than by day, and it has been a matter of discussion ever since as to what is the cause of that variation. Several observations have been made at the time of sunset, covering the "sunset effect," and part of the results are recorded in figure. The first point which deserves notice is that the increase in

Graphical Chart of Variation in Strength of Radio Signals.

strength of the signal does not occur at the time of sunset, but some time afterward. This is what might have been expected if the state of ionization of the atmosphere is the controlling factor in determining the signal strength. The increase in signal strength occurs at almost the same time as daylight ceases, i. e., at the same time as the number of ions per cubic centimeter in the atmosphere would rapidly diminish.



The curves presented, however, indicate that the sunset effect varies with the weather conditions at the time of sunset.

The day strength of the signals varies within comparatively narrow limits, but the average strength of the signals during June and July is noticeably less than that during December and January. The lower curve shows the variation for one month, day by day, in strength of signals.

The variations in strength of signal from day to day are comparatively slight, but they are noticeably greater for March and July than they are for December and January.

A COMMERCIAL TYPE HELIX.

The wireless sending helix in most amateur stations is generally a cheap affair and oftentimes it is very inconvenient to use. An idea is here given which follows some-

Commercial Style Helix for the Amateur.

what the design of several commercial helices and loading coils for transmitting purposes. In making this design it is best to construct the two uprights A and the top cross-piece, of hard rubber or some well-dried hardwood thoroughly boiled in wax.

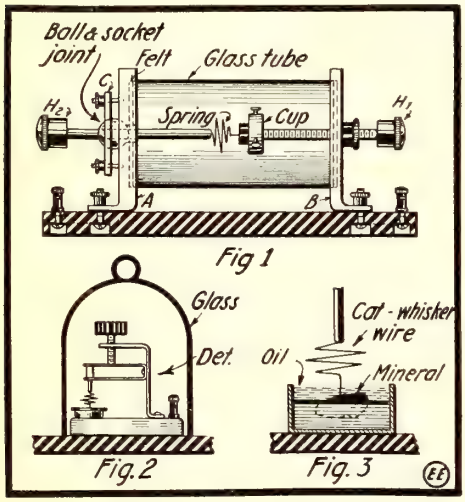
Eight to twelve turns may be used in the helix, about 6 inches in diameter, and spacing them ⅝ to ¾ inch apart. The wire may be about No. 6 B. & S. for small sets and of aluminum, brass or copper. Contact with one side of the circuit to any number of any complete turns is given by means of a jackboard B, detail of the construction of same being given in the sketch. By arranging a rotary knob and contact arm with wheel for the top turn, it is possible to quickly make conection with any part of one turn, as will be evident. The top turn of wire should, therefore, be made practically horizontal as regards all parts of the turn, so that the wheel will follow around same quite truly.

The jackboard and receptacle for same may be purchased from any telephone supply company, or they can be made up by the experimenter who happens to have a lathe at hand. A wax impregnated wood base may be used for the helix, etc. The other side of the circuit is connected to the rotating arm K, through a brass strip D and post C.

L. Hildebrand, of Denver, Colorado, writes us:

"I take your *'Electrical Experimenter'* and I sure think it is a dandy paper. I don't believe I could do without it."

"Your November issue of the *'Electrical Experimenter'* was the first that I have seen and I am very pleased to find it such a fine magazine. I buy about six different electrical and mechanical magazines a month, and I think this is one of the best ones published for the young Experimenters."



IMPROVEMENTS ON DETECTORS.

Of all the amateur wireless detectors in use to-day probably not 3 per cent. are properly covered up to protect the crystals against dampness and dust in the air. The best detectors are generally covered by a glass shell in some way, such as Fig. 1 shows. Here a threaded brass rod and handle H_1 pass through a threaded hole in the upright B. This rod carries a cup to hold the crystal, and also is tapped and fitted with three thumbscrews to clamp it with. The glass tube or cover is secured in place between the metal uprights A and B, in felt-lined grooves turned in them, as will be seen.

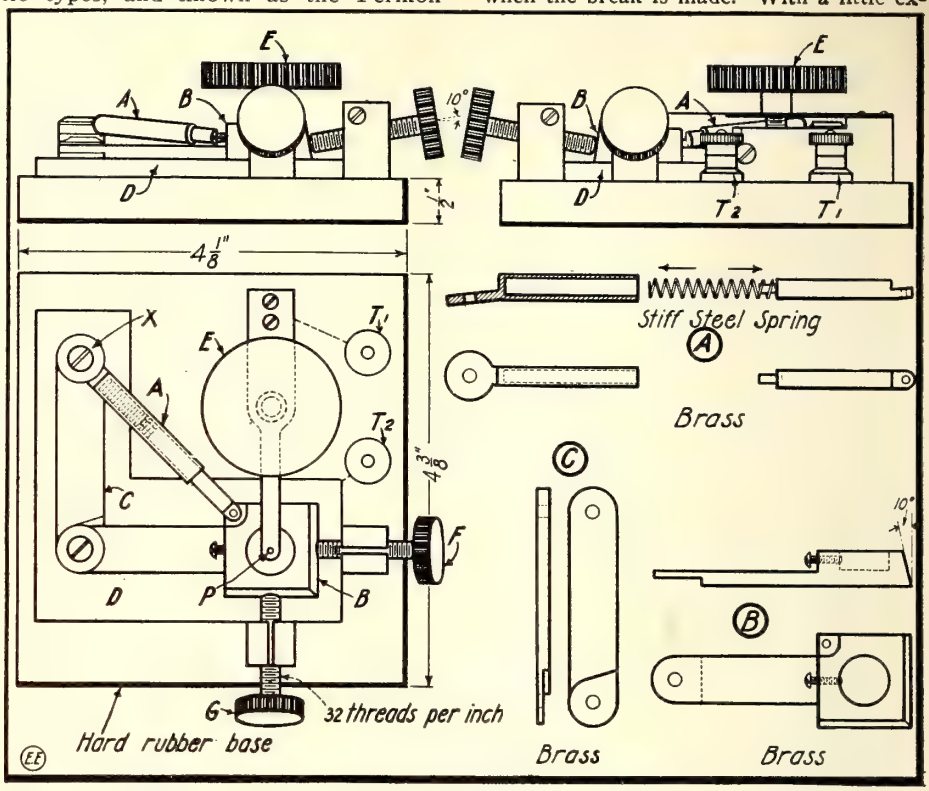
The cat-whisker wire, in the form of a spiral preferably, is carried on an arm H_2 which fits snugly but not tightly in a ball clamped under a bar C and two thumbnuts. The ball can be split on one side if desired, to clamp the rod more tightly whenever the bar C is tightened up. Thus the rod H_2 can slide lengthwise through the ball and around any angle over the face of the crystal owing to the ball and socket joint formed. The base should be nothing but glass, hard rubber, fiber or marble for highest efficiency. Molded composition is all right also.

At Fig. 2 is seen the easiest manner in which to cover over your detector to keep the dust out. A glass laboratory or watchmaker's bell is placed over it. It may be arranged in a wooden frame and hinges, so it can be tipped back, permitting of quick accessibility to the detector for readjustment.

It is well to cover the mineral with oil, as depicted at Fig. 3, to keep the crystal in first-class shape. Paraffine or other oil can be used.

Three Methods of Improving Detectors.

THE SENSITIVITY OF THE TELEPHONE RECEIVER.

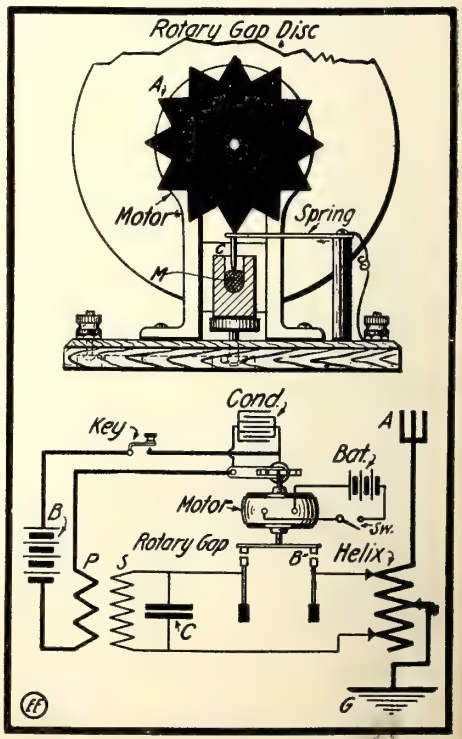


It is truly marvelous how sensitive an ordinary telephone receiver is. Preece calculates that a sound is produced in a telephone by current equal to .000,000,000,000,6 (six ten-trillionths) of an ampere in intensity, or such a current as could deposit about .000,000,000,000,03 (three hundred-trillionths of a cubic inch of pure copper in each second of time.

Pellatt calculates that with a voltage of .0005, representing the difference in potential between the two terminals, an audible sound is maintained in the receiver.

Above values may be multiplied by 10 to 25 times if the instrument is a modern wireless telephone receiver.

THE PERIKON-ELECTRA DETECTOR.



A new radio detector invented and patented by G. W. Pickard, sponsor of the present silicon, perikon and iron pyrite types, and known as the Perikon-Electra detector, is illustrated by the drawing here shown. This instrument consists principally of a very clever mineral stand which by means of properly designed adjustment screws permits the operator to quickly move the mineral cup B to whatever position desired under the contact point of steel or brass, P. Pressure on the point is varied by turning the thumb screw E. Details of the parts B and C are shown in the drawing, as well as the stiff spring and barrel A. The spring A is of the expanding type and when the mineral cup is mounted on the lever system, B—C, swinging on a fixed pivot X, secured to the base frame D, the spiral spring A tends to force the mineral cup B up diagonally against the two adjusting screws F and G. These screws are inclined at an angle of 10 degrees from the horizontal and exert pressure downward on the 10-degree tapered sides of the cup. Hence it becomes possible to simply adjust either screw, F or G, and thus move the mineral about under the contact point until the most sensitive spot is found.

A Detector for Radio Purposes, Capable of Quick and Accurate Adjustment.

MERCURY BREAK AND ROTARY FOR SPARK COILS.

The accompanying drawings represent a simple apparatus for obtaining a synchronized spark of a fairly high frequency from a battery-operated spark coil. B is an ordinary rotary spark gap with twelve zinc plugs. A is the contact breaker which takes the place of the vibrator on the spark coil. It is made of hard rubber or wood cut out with twelve points which, when rotating, make and break the current for the primary by making the brass point C come in contact with the mercury M contained in the carbon cup. A condenser should be put across the points of contact to reduce sparking. The cup is adjustable. The break disc should be set in such relation to the gap that the break occurs just as the plugs on the gap are approaching the stationary electrodes. The quicker the action of the spark coil the shorter must be the distance between the plugs when the break is made. With a little experimenting the right distance will be found. The apparatus is driven by a battery motor. With a motor speed of about 2,000 r. p. m. a spark frequency of about 400 per second will be obtained. Amateurs depending on batteries for transmitting will find that this machine will give a much higher pitched spark than with spring vibrator. The motor does not take much battery power to run.

Intensifying Radio Signals.

By Henri Sécore.

SEVERAL unique schemes for intensifying the weak signals received in radio-telegraph stations are mentioned in the French journal, T. S. F. (Télégraphie Sans Fil), and we describe the more interesting of these simple arrangements for intensifier experiments herewith.

The first method of constructing an intensifier is that illustrated at Fig. 1, where three carbon pieces C, C, C1 are mounted delicately on the diaphragms of two high resistance radio receivers T T. These receivers TT are joined in the place of the regular head 'phones of the wireless receiving circuit. The carbon piece C1 is pivoted between two indentations in the faces of the two upright carbon blocks C C, thus forming a microphone. When the diaphragms of the wireless 'phones T T move, due to incoming signal current acting on them, they also cause the resist-

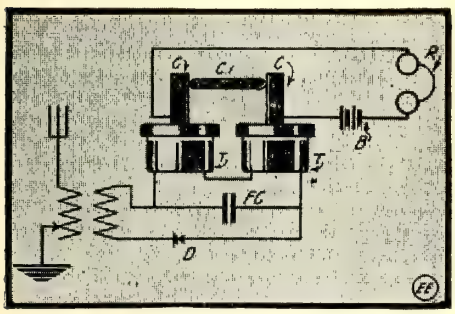

Fig. 1. Microphonic Form of Amplifier.

ance of the carbon block circuit or "microphone" to vary. This action causes a strong local battery B to act on a second pair of 'phones R, which can be 75-ohm type receivers, etc.

Another *stunt* is that outlined in Fig. 2, where a phonograph reproducer P with horn H is caused to give loud signals by virtue of the stylus or reproducer point resting on the diaphragm of a 75-ohm receiver T. This receiver is acted upon by varying current strengths from a battery B through a carbon grain microphone M. This microphone has its mouthpiece removed and is carefully placed in position against the diaphragm or cap of the high-resistance 'phone R, connected to the regular radio set. It may be remarked that the Editors have found these arrangements to work best when the diaphragm of the microphone M is glued or otherwise rigidly connected with the receiver R diaphragm.

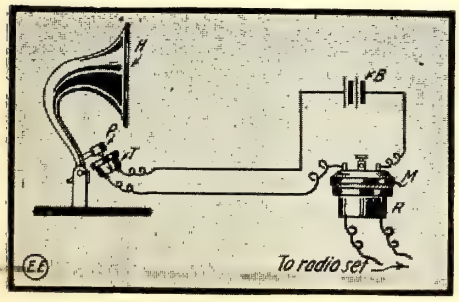

Fig. 2. 1,000 Ohm Receiver and Microphone Form This Amplifier Together with Phonograph.

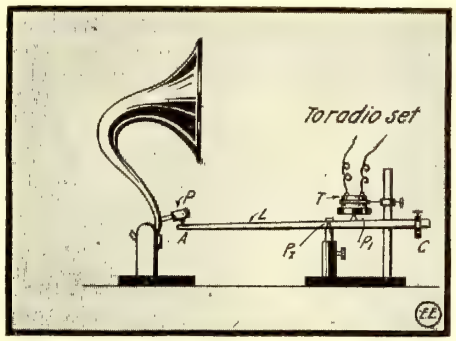
A scheme similar to the last one was advocated by Stanley Hyde in *Modern Electrics*, but in a simpler form, i. e., the phonograph reproducer stylus was placed in contact with the diaphragm of the high-resistance wireless 'phone directly. Here, however, there is a chance to amplify the



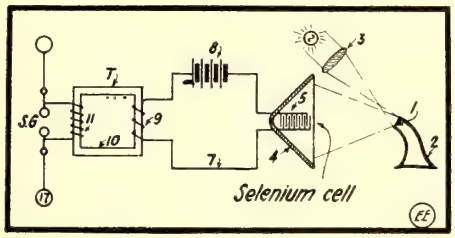


Fig. 3. Amplifying by Lever Action.

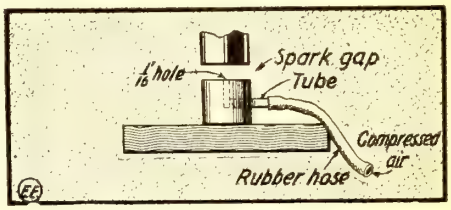
signals by controling the microphone "booster" circuit T M B. Those not having access to a phonograph reproducer may simply place a good size horn on the receiver opening of T, the diaphragm vibrations of it being heard then in the horn H.

The old principle of unbalanced lever action is employed in the arrangement indicated at Fig. 3. In this outfit, as shown, a delicately pivoted lever L is caused to act on the phonograph reproducer stylus P, at A, whenever the opposite end of the lever point P1 is acted upon by the movement of radio receiver (T) diaphragm. As is well known, if the lever is pivoted at P_2, or off center, then an increased motion radius is given at A, compared to the motion radius imparted at P_1, and which difference in movement amplitude is directly proportional to the ratio existing between the long and short arms of the lever L. A, C is a balance weight. The pivot P_2 is movable up or down on fulcrum rod with setscrew and sleeve as indicated.

SELENIUM CELL FOR WIRELESS TELEPHONE CONTROL.

A recent patent issued to a Brooklyn, N. Y., inventor possesses some very inter-

esting points which will, though perhaps not immediately practical, nevertheless become useful, undoubtedly, when the well known selenium cell is more perfected.



The diagram here given shows how this inventor intends to make use of the properties of the selenium cell (which lowers its resistance when a strong light is thrown on same, and vice versa) by placing the selenium cell 5 in the focus of a reflector 4. A mouthpiece 2, into which the voice waves are projected, has fitted on its inner end a small mirror 1. As the varying voice air waves impinge against the diaphragm and its mirror 1, it causes a corresponding varying beam of light to be projected onto the cell 5. This light is projected onto the mirror from some source of illumination placed behind lens 3. The selenium cell thus causes a changing resistance corresponding to the voice fluctuations at 2 to react through the transformer circuit 7, 8, 9, and thus sets up corresponding spark waves in the secondary of this transformer, as will of course be evident.

AN AIR BLAST SPARK GAP.

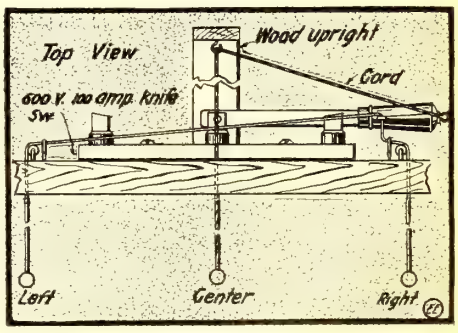
The spark gap has long been known as the most wasteful piece of apparatus in the sending set. The result is that experimenters have spent much time trying to overcome its disadvantages.

The object of special rotary gaps, etc., is to hold up the resistance of the gap, which falls very low, due to the heat of the passing spark, and also to the ionization of the air in the gap. By cooling the gap the former is done away with and an air blast will accomplish the latter by blowing the ionized air from the gap similar to a rotary type gap.

An air blast gap can be easily made from a plain zinc spark gap that will give good results. Remove the lower zinc plug and drill a 1/16-inch hole through its center. Drill another hole ⅛ inch diameter into

Compressed Air Spark Gap.

one side, so it will connect with the small hole. A brass or copper tube 1 inch long is forced into this hole to make a tight fit.



Replace the plug in the stand so the tube will project out at the back. The gap is connected in the circuit and a small rubber tube is slipped over the brass tube and long enough to reach the floor.

The air may be supplied by a bellows operated by the foot; or a better way would be to get a small tank and compress air into it and regulate its flow to the gap by means of a valve.

THOMAS W. BENSON.

INDOOR LIGHTNING SWITCH CONTROL.

Herewith is diagram of how I made a grounding switch attachment for my aerial, that is very convenient. It is very handy, and instead of going out in the yard on muddy and rainy days, by pulling the middle string the knife blade is brought into upright position. The other two strings (left and right) will ground or connect the aerial to the instruments. Small pulleys

Aerial Switch Controlled Indoors by Means of Three Ropes.

are best employed to pass the cord around bends and into the small holes cut through the window frame.

The D. C. Arc for Wireless Telegraphy and Telephony

(Concluded)

Majorana's Liquid Transmitter.

The illustration at Fig. 15 explains the principle of Majorana's transmitter. When water passes thru a small hole in the end of a tube, as shown at A in the diagram, it continues to flow in an unbroken column for some distance and then it breaks up into drops as shown at B.

Majorana's transmitter is shown on the right-hand side of the diagram. Tube A is in this case fitted with a small elastic

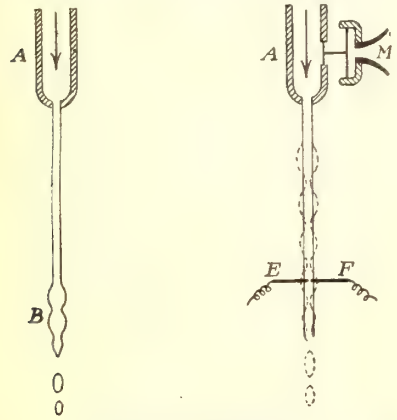

Fig. 15. Showing the Principle of the Water Stream Microphone.

partition near its end. This is attached to a rod leading from the diaphragm M. Two small rods or plates E and F are arranged near the bottom of the column just above the place where it forms into drops. These rods just enter the column a very little way and are connected to the circuit conveying the current which we wish to control by the voice.

Now, on speaking in front of M, vibrations are conveyed to the liquid by the rod from the diaphragm, and a sort of wave motion takes place down the column as shown in this diagram, its form depending on the voice, so that the electrical resistance of the column between the two rods is continually changing in exact accordance with the sound waves acting on the diaphragm.

The conductibility of the column can be varied within certain limits by the size of the hole in the tube and by the character of the liquid employed, whether it be acidulated water, salt water, mercury, etc., and also by adjusting the distance between the rods.

Vanni's Liquid Transmitter.

At Fig. 16 is depicted the transmitter which was used recently by Dr. Vanni in Rome in connection with a Morretti arc generator. Successful transmission of speech was accomplished between Rome and Tripoli, a distance of over 600 miles.

A small jet of acidulated water passes thru nozzle N on to a small plate F attached to diaphragm D; it splashes off this on to a fixed plate G; every movement of the diaphragm alters the resistance of the liquid between the two plates. The diaphragm may either be operated on directly by the voice, or it can be connected to a distant telephone circuit by means of the electro-magnetic device shown here.

Now a word or two as to the reception of signals when arc generators are employed for transmission.

When telegraphing, the arc generator is kept working all the time, and the signals are transmitted by shorting several turns of either the primary or secondary inductance by means of a Morse key, thus putting the transmitter either into or out of tune with the receiving station by altering its wave-length.

Fig. 17 shows Poulsen's connections for reception. As no interrupter is employed at the transmitting station to break up the wave train into groups of waves whose frequency is sufficiently low as to be audible in a 'phone, no signals can be heard with ordinary receiving connections. A small vibrating contact-breaker is, therefore, employed at the receiving station, known as a tikker. When using this instrument no detector is required. Its action is as follows:

The receiving circuit is intermittently connected by a tikker to a large condenser O (about 1 microfarad capacity). During the time of contact the condenser becomes charged, and when the contact is broken it discharges thru the telephone, producing a note corresponding to the frequency of the tikker interruptions. Mr. Child, of the London Telegraph Training College, has very kindly lent me a tikker which I shall be very pleased to show to anyone interested at the close of the lecture.

For the reception of speech, the detectors and connections used are similar to those for spark signals, the most sensitive detectors being those of the crystal type, such as Pickard's original silicon detector, or a zincite and copper pyrites detector. Electrolytic detectors are particularly reliable for telephony, and Fleming's oscillation valve also acts very well.

Fessenden has invented a very clever telephone receiver, which he terms the "Heterodyne." It consists of two small coils, one wound on a fixed core of fine iron wires, and the other attached to a mica diaphragm having its plane parallel to the first. The first coil is connected to a local source of "high frequency" current tuned to agree as exactly as possible with that of the transmitting station; the received oscillations pass round the diaphragm coil. The mechanical

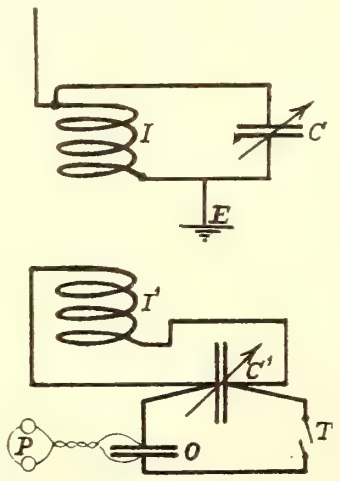

Fig. 17. Poulsen "Tikker" Receiving Connections.

force between the two coils varies in accordance with the voice at the transmitting station and reproduces the words spoken.

I have been experimenting myself for some time past with a hot wire telephone on the principle of that invented by Pierce for line telephony in 1880. I find that this telephone can also be connected direct to the oscillating receiving circuit without the use of a detector; but, as you see, the apparatus is very crude and is no doubt capable of much improvement. As this is a lecture on arc systems, I have made very little mention of H. F. alternators.

There is, however, very little doubt that in the near future the Goldschmidt H. F. alternator will be used for wireless telephony, and Professor Fleming thinks that by its employment even Transatlantic wireless telephony may be possible. The time is probably coming when we shall be able to converse with our friends at sea from our own houses, using telephones similar to those so many of us already have installed. We shall ring up the Telephone Exchange

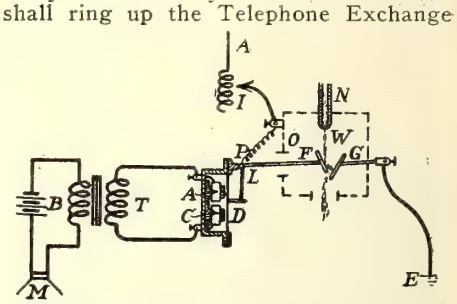

Fig. 16.—Dr. Vanni's Liquid Transmitter. A Variation in the Liquid Stream N is Caused by the Magnet Coils A-C and diafram D.

and ask to be connected to some large wireless telephone station on the coast, and the operator there, having got into communication with the ship to which we desire to speak, will connect up our simple telephone circuit to his elaborate wireless instruments, to which he will attend while we converse.

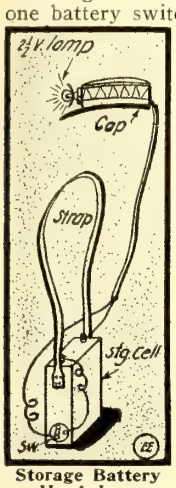
The paper was followed by an interesting debate.

Dr. Erskine Murray, after thanking the lecturer, said that rather debatable ground had been touched on by the lecturer in reference to the Lepel system. It was by no means certain that both the primary and secondary oscillations took place through the spark gap. With reference to the Poulsen system, he said that he had himself, several years ago, seen a Poulsen arc working continuously, without adjustment, for over a quarter of an hour, and it was a great wonder that wireless telephony was not made more use of commercially.

Mr. Binyon said that reference had been made to the Goldschmidt alternator. He was himself employed by the Goldschmidt Co. and was glad that the lecturer was so optimistic as to its future; but he thought that Transatlantic wireless telephony, altho in all probability on the verge of accomplishment, would never become of great commercial value. Transatlantic telegraphy is carried on at high speed in order to cope with the enormous number of messages transmitted. Too much time would be taken up by telephony, and people would not care to carry on important conversations to which any amateur station could listen.

Mr. Maurice Child made some very humorous remarks as to the result of wireless telephony in the Channel. He suggested that some very bad language might be heard if all sea captains were to try and speak to each other at once by wireless telephony.

Mr. Leslie Miller stated that he had seen aluminum used in place of carbon for hydrogen arcs with very good results.



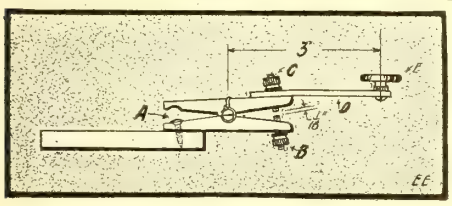
HOW-TO-MAKE-IT DEPARTMENT

This department will award the following monthly prices: FIRST PRIZE $3.00; SECOND PRIZE $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

FIRST PRIZE $3.00

A STORAGE BATTERY HANDY LAMP.

Campers, cyclists and Boy Scouts will find this lamp extremely handy and practical. The articles that are used in constructing this lamp are: One storage cell, one battery switch, one 2½-volt lamp, one miniature socket, 10 feet of annunciator wire or lamp cord.



Storage Battery Head Lamp.

The remaining smaller articles can be found around the house. After your storage cell has been charged set it in the pasteboard box that it originally was received in, or better, make a metal carrier for it. Then fasten a leather strap on both sides of the box so it will fit comfortably on your back. Take another piece of leather and make a head band to put around your hat or cap and rivet the miniature socket to it, as shown. On the bottom of the wooden battery switch drive a small nail and bend so as to make a hook to fasten the switch to your coat or any other part of your clothing. Make or buy a little reflector of polished tin or nickel to fasten on the socket. Connect as illustrated and your lamp will be ready for use.

HAROLD B. FINKELSTEIN.

A CHEAP TELEGRAPH KEY.

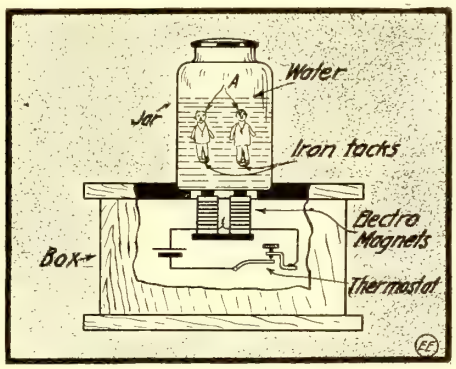
A very simple key for experimental wireless work can be made very easily. Procure a piece of wood 3x3 inches and give this a good coat of shellac. Next, get a spring clothes pin and fasten this at A, leaving 1½ inches of the pin projecting

Telegraph Key from Clothes Pin.

from the board. Bore a hole in the upper and lower pieces about ½ inch from the ends. Procure two binding posts off some old batteries, and fasten these in the holes, having them about ⅛ of an inch distant, with clip in normal position. The wires can then be attached at B and C, as shown in the diagram. Place a strip of brass D, under the nut C, with a telegraph knob, E, at the outer end, or the knob may be placed on screw C.

Banana oil or turpentine is excellent for pasting tinfoil on transmitting condensers.

NOTICE!!!



We wish to buy May, '13, Oct., '13, and Jan., '14, copies "E. E." Address the Editor.

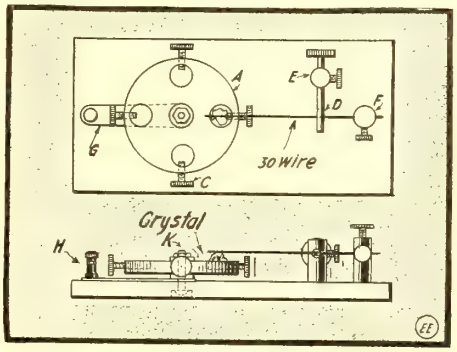
SECOND PRIZE $2.00.

A NOVEL ELECTRICAL WINDOW ATTRACTION.

A novel attraction for a window display can be made from a fruit jar filled half way with water and supported over two electro-magnets, which are mounted in a box or covered over with some cloth as shown in illustration. Two or three small figures A are made from cork and painted with some white paint. Now insert on bottom of each figure A an iron tack or a small iron nail.

When everything is ready connect the electro-magnets in series with a thermostat and place the figures in the water. As soon as the current is made the figures will dive to the bottom of the jar, and when the magnet is opened the figures will rise again

Electrical Window Attraction.



to the surface. The operation is continuous as long as the thermostat makes and breaks the circuit. Thermostats are readily purchased in any electrical store.

CONTRIBUTED BY L. WEISS.

A ROTARY "CAT WHISKER" DETECTOR.

For all around service the universal or cat whisker detector gives good results. The cat whisker detector herewith described is easily made.

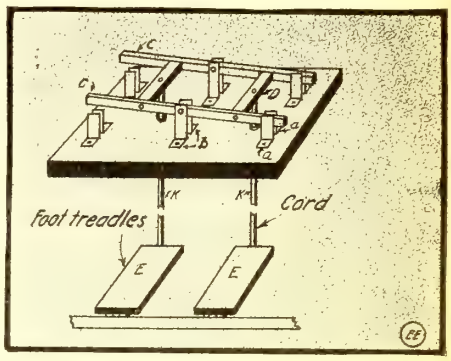
The cup A is made of brass ⅜ inch thick and 2½ inches in diameter. The

Rotary Mineral Holder.

holes are ⅝ inches in diameter. The brass screw K holds A to the base, so that it can turn. G is a brass strap 1/16 inch thick and ⅜ inch wide which connects A to the binding post H. This strap is not necessary as the connections can be made with wire under the base. Electrical connections are made with H and F.

All the parts should be nickel-plated and polished.

THIRD PRIZE $1.00.



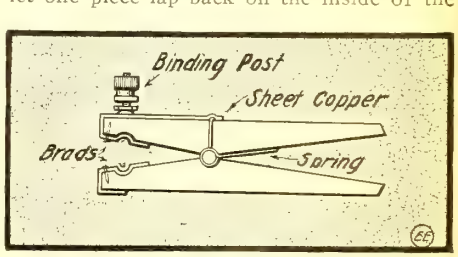
A FOOT-CONTROL AERIAL SWITCH.

This switch is designed to give rapid switching of the aerial circuit connections to the foot control of the operator. When he is using his instruments he sometimes finds it rather difficult, after sending, to throw the switch and make all the necessary adjustments before the return call commences to come in. This device, by eliminating one movement at least of the hands, saves time.

The sketch illustrates all the parts required. If desired the eight parts A may be substituted by four parts made in one piece; the same also applies to B. The instrument may be mounted directly on a table or may have a base, and may then be placed on the table, through which the holes for the treadle cords have been previously bored.

Too much pressure should not be applied to the treadles, as undue strain might injure the switch.

The blades CC can be of copper or brass bar about ⅛ to ⅛ inch thick by ½ inch wide and 8 to 10 inches long. The



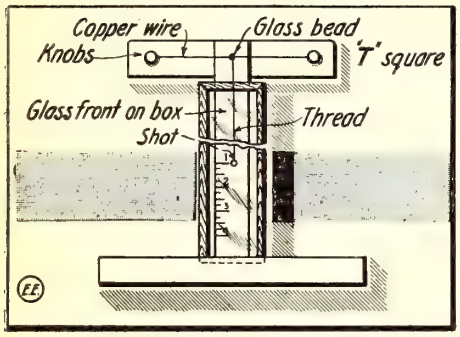
Foot-Operated Aerial Switch.

base is best made of waxed wood or marble. The jaw contacts AA, etc., should have their upper ends slightly flared out so the blades will enter them without binding. The cross bars DD are of fiber or hard rubber. Contributed by

A. D. R. FRASER.

A HELIX CLIP.

An efficient helix clip may be made from an ordinary spring clothespin. Fasten a thin piece of sheet copper on the inside of each jaw of the pin, using small brads, and let one piece lap back on the inside of the



Helix Clip of Simple Construction.

pin for about half an inch. Solder a flat head 8-32 machine screw on the overlap and screw a nut from a dead dry cell on this to form a binding post,

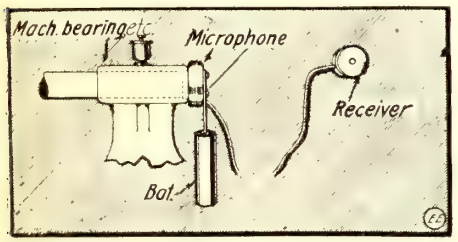
"SIMPLEST" HOT WIRE AMMETER

The diagram shows how to make a simple but accurate device for finding the best radiation of a radio transformer of a half kilowatt or over. The device is simple and can be made by most every wireless experimenter.

Two small knobs are attached to the head of the T-square and a No. 36 copper wire stretched between them. From the

Very Simple Hot Wire Ammeter.

center of this wire is suspended a small lead shot on a silk thread, with a glass bead.



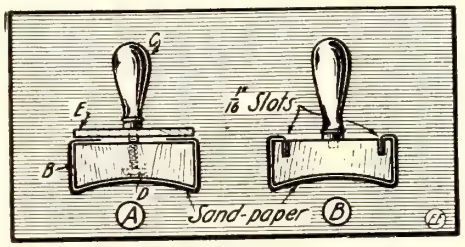
When put in series with the ground, the wire expands, causing the shot to drop slightly; and, after adjusting the helix clips till the shot is lowest, the greatest radiation is obtained.

For some transformers the wire may have to be larger or smaller than 36, depending on the transformer used.

Contributed by
RANDOLPH ROLAND.

DICTAGRAPHS FOR TESTING MACHINERY.

The ultra-senitive telephone set, commonly known as the Dictagraph or Detectiphone, is applicable to many different problems encountered in every-day work. A very useful application of this instrument to the requirements of machine erectors, etc., is illustrated in the sketch. Here the extremely sensitive microphone transmitter of the dictagraph is placed in contact with the metallic frame of the machine or, in the case of a shaft bearing, at the end of the journal housing, as seen in the cut.



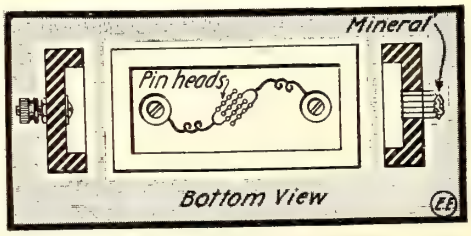
Dictagraph Helps Machinists to Hear Knocks in Machinery.

By listening in the telephone receiver of this set the slightest knocks or other undue noises in the machine, which would not, perhaps, be perceptible to the ordinary ear unaided, will be heard plainly in this instrument. This form of telephone is simply a series instrument, and the battery, microphone and receiver are all joined in series. It is therefore easily possible to rewire same and place the battery at any point in the circuit desired, or the circuit may be made as long as 50 to 75 feet. No. 16 lamp cord can be used for the circuit under such conditions.

Always connect the lead-in wire from your highest point and avoid leaving kinks and unnecessary turns in it.

SAND-PAPERING COMMUTATORS.

One of the commonest jobs the electrician around motors in industrial plants has to bother with is keeping the commutator in good shape. All commutators at some time or other tend to burn and blacken a little bit, and a common remedy to smooth them while they are running is to apply a piece of sandpaper. We show herewith a couple of commutator blocks made out of hardwood suitable for holding a piece of sandpaper nicely without fear of shock to the electrician or motor attendant. In the model shown at A a back piece of wood E is caused to clamp the sandpaper tightly when the handle C is tightened up by means of its threaded stud and nut secured in a recess in the center of the block, this nut being, of course, square or hexagonal in form so as not to turn. The second form of sandpapering block at B in sketch is very simple to make, and has two 1/16-inch slots cut in the two sides of same at the back. The sandpaper is then simply fastened in each slot, and may be held by a thin piece of wood if desired. In either case it should be noted that for best results, and as followed out in one of the largest industrial plants of the country, it is al-



Sand-Paper Blocks for Dressing Commutators.

ways best to have several of these blocks with different radii curves on their faces to cover the range of several sizes of commutators which may be around the plant. It is not advisable to use a flat block face.

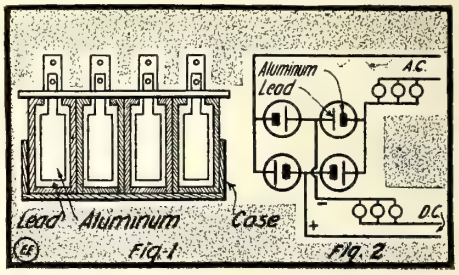
A useful hint in this direction lies in the use of a common scythe-sharpening stone, which is quite soft and nonconducting. When a commutator is badly cut and temporary improvement is necessary in the operation of the motor such a stone is pressed on to the commutator, and it is thus dressed down while running. Always use sandpaper for commutator work and never emory paper.

PIN-POINT MINERAL TESTER.

The pin-point detector and mineral tester is constructed with two battery screws, two battery thumb nuts, two washers, 16 common brass pins, one block of soft wood 3 inches long by 1½ inches wide by ¾-inch thick. Hollow out the block, as is shown in drawing, leaving the sides, ends and tops one-quarter of an inch thick. In the middle of the block drive your pins in rows, being careful that the

A Pin-Point Mineral Tester.

pins do not touch each other and allowing the points to project through the top about one-sixteenth of an inch. Connect the pin-heads as shown in drawing, soldering the lead wires to the pin-heads and binding screws. Place a piece of mineral on the pin points as in drawing No. 1. To adjust the detector rap it lightly so as to jar the mineral.



This detector will be found very handy for testing mineral, as there is no adjustment screws to handle. I find this detector much more sensitive than anything I have ever tried.

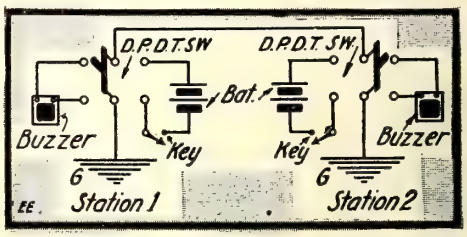
Contributed by C. P. STONE.

HOW TO MAKE AN ELECTROLYTIC RECTIFIER.

A very simple device which will change an alternating current to a direct current can be constructed for less than a dollar.

First obtain four jars (see Fig. 1) and place them in a suitable box. Next obtain a board just large enough to go across the four jars. Mark a circle on the board under each jar. Mount then an aluminum

Four Cell Electrolytic Rectifier.



and a lead plate ½-inch apart under each circle, as shown. The lead plates should be a little larger than the aluminum plate; a suitable size is 4x6x⅛ inches. Both plates can be fastened to the cover by bending over a ⅜-inch ear at the top and using some wood screws.

Fill the jars to within 1 inch of the top with an electrolyte made by dissolving as much sodium phosphate as possible in the water and adding a few drops of sulphuric acid for low voltage rectification, such as 12-20 volts, etc.; connect the cells as shown in Fig. 2. This rectifier may be used on an alternating current circuit up to 220 volts. On 110 volts it will give 3 to 3½ amperes D. C. at 80 volts, and on lower voltages it will operate with reasonable efficiency. It will take about half an hour for the plates to form after the alternating current is turned on. Both halves of the cycle are rectified with this rectifier.

A BUZZER TELEGRAPH SYSTEM.

The sketch, I think, will be interesting to your readers.

The diagram shown is for an open circuit telegraph set that most anybody can easily put up. It requires the following apparatus: Two D. P. D. T. switches, two

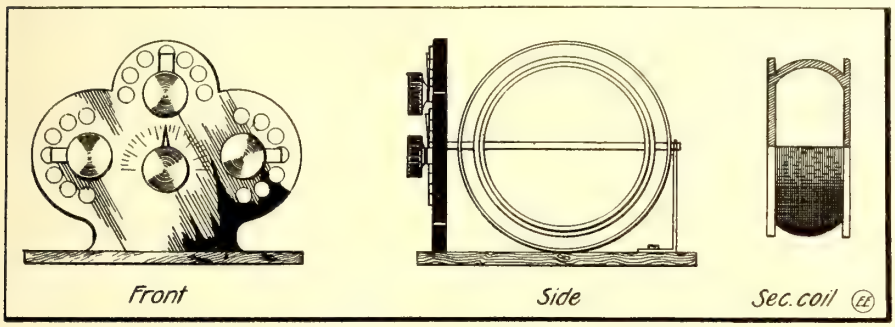
Simple Buzzer Telegraph System.

buzzers, two keys and batteries. To operate the set the switch handle is always left on the receiving or buzzer side. When the operator wishes to send he throws it on the right and calls the other party.

I have used this set for some time and get fine results.

Contributed by FRANK HARAZIM.

AN UNUSUAL COUPLER.

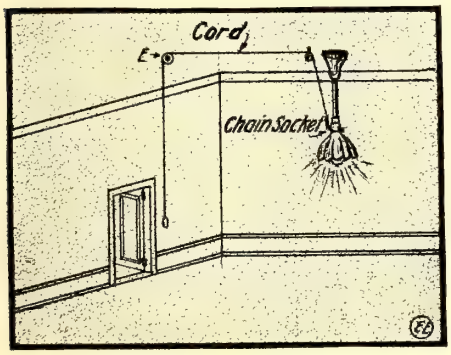


It is a well-known fact that the efficiency of most receiving sets is very low. This loss is due to the inefficient method of transforming the oscillations from the antenna to the closed or detector circuit. This loss is especially great when two couplers are connected in cascade for elimination of interference. The coupler here described, although not new, is seldom, if ever, seen in the amateur station.

We know that when undulations energize the aerial it sets up a weak magnetic field about the primary. Now, in order to energize the detector circuit to a maximum it is up to us to construct a secondary suitable to absorb the most lines of force. So we make a form like the one in illustration, which has many advantages over the common cylindrical form. This can easily be turned on a lathe.

Start winding your coil from both ends and then solder them together at top, taking taps about every twenty-fifth turn to vary inductance. Any number of layers can be used.

The primary coil is of the common variometer type. Start winding at either end, taking taps first 10 and then every other 10. This eliminates the losses otherwise due to sliders. Sizes 24 and 30 B. & S. wire are suitable for primary and secondary, respectively. The illustration elucidates the minor details. A coupler built similar to this is very efficient and gives a handsome appearance, as sought by every up-to-date experimenter.



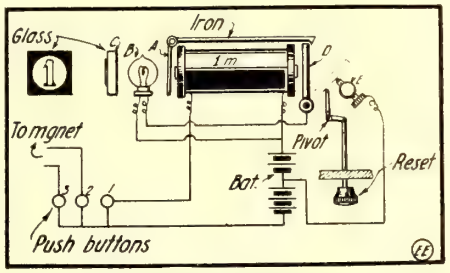
Contributed by ROBT. C. MARTIN.

Particularly Efficient Form of Loose Coupler with Spherical Secondary.

CONTROLLING LIGHT FROM THE DOOR.

Quite frequently rooms are lighted by pendant fixtures which are turned on and off by a pull-chain socket at the fixture.

Controlling Electric Lamp by String.



This makes it necessary to grope through the dark room in order to find the chain. This annoyance may be obviated by the use of a piece of cord and two screw eyes E, as shown in the drawing. Screw pulleys would be better but are not necessary, as the cord will pass easily through the eyes. A small porcelain insulator hung on the end of the cord will serve as a hand grip and will also tend to keep the cord taut. By using a cord of the same color as the paper over which it passes a very neat job may be made indeed. A rubber band may be placed in the cord line so as to prevent severe jerking of the socket mechanism. Contributed by

HAMILTON A. HOOPER.

FLASH-LAMP ANNUNCIATOR.

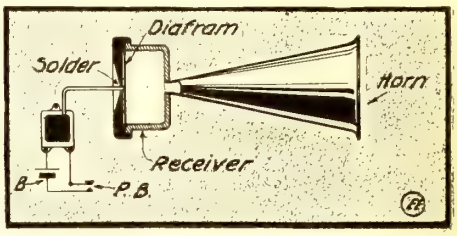
A different form of indicator or annunciator than the one we are all more or less familiar with is the subject of these few lines. In many cases it is very desirable to have an annunciator operating on the same principle as the telephone switchboard, i. e., where the signals are flashed by means of small lamps placed behind glass bull's-eyes with numbers painted on them.

The arrangement shown in the sketch herewith indicates a very simple arrangement, easily constructed by the amateur electrician and at small expense. Also the principle can very well be carried on to include quite a number of indicators, as will be evident. Briefly, the principle of this flash light indicator is as follows:

Flash-Lamp Annunciator.

An electro-magnet 1M has fitted onto it a soft iron armature A, pivoted as shown; so that when an electric current passes through the magnet coil it will attract the shorter end of A, and thus release the brass switch drop D. This drop then falls onto the contact screw E, thus closing the flash-lamp circuit through the battery. Primarily the signals are sent into the indicator to the respective magnet coils 1M, etc., from the push puttons 1, 2, 3, etc., placed in various parts of the building. The glass disc C can be made of ordinary glass and the front of same painted with some lampblack as shown. After each signal has been answered by the attendant the drop D is readily reset by the small button as shown in sketch.

HINT FOR CONDENSER MAKING.



Use a warm, flat iron, instead of the old-time hot knife and roller, to make your condensers and you will be surprised at the ease with which it can be accomplished. The condenser will be much more compact than it could possibly be made by rolling, thus increasing the capacity likewise.

Contributed by

ARTHUR R. DARLING.

HOW TO MAKE AN ELECTRIC HORN.

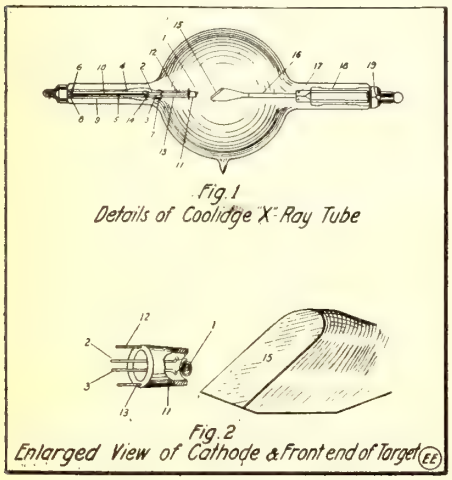
The following material will be needed in building this horn: An old watch case receiver, an electric bell and a wood base of any size; also a block for the bell to rest on. Now remove the magnets from the receiver and drill a 5/8-inch hole through the back of the shell. Next procure a tin horn at a toy store for about 10 cents and remove the whistle on the inside. Next cement the horn to the holder in the back of receiver, or solder it in place if the shell is of metal. That having been done, replace the diafram and screw the cap on. Next cut the ball off the tapper of the bell, remove the gong and bend the rod at right angles as shown in figure. Then solder the end of the arm to the diafram. This horn will give a loud sound, especially if used on five to six dry cells B. A push button is placed at PB.

Easily Made Electric Horn.

SPARK PICTURES.

The photos of sparks herewith reproduced were taken with a one-inch spark coil, but the batteries were run down and the sparks would only jump a half inch. However, the picture turned out quite satisfactorily. For the benefit of the reader I will describe the experiment. The material used consists of a photographic plate, metal plate, talcum powder, two pieces of wire and a needle. (The photographic plate should not be exposed to any light.)

First of all fasten one wire leading from either of the secondary posts of the spark coil to the metal plate. Place the photographic plate on the metal plate, with the gelatine side up, and sift the talcum powder through a piece of cheesecloth evenly over its surface. To the other secondary post of the coil fasten the other wire. Attach the needle to the other end and hold it on the middle of the plate. Make one spark, brush off the powder and the plate is ready for developing. Startling results can be obtained if the above is carried out correctly.



Contributed by WM. A. STEPHEN.

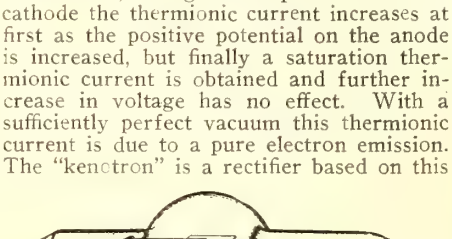
THE NEW COOLIDGE X-RAY TUBE

The new Coolidge X-ray tube is a direct outcome of Dr. W. D. Coolidge's previous invention of ductile tungsten, the physical properties of which enable its substitution for platinum as the target or anti-cathode in X-ray tubes.

The Coolidge tube is shown in detail in Fig. 1, while Fig. 2 gives details of the cathode and front end of the target.

The construction of the cathode can be seen from Figs. 1 and 2, in which (1) is a tungsten filament forming a flat, closely wound spiral. This tungsten filament (which consists of a number of convolutions) is electrically welded to heavy molybdenum wires (2 and 3), to the other extremity of which are welded the two copper wires (4 and 5), these being in turn welded to the platinum wire (6). To insure rigid support for the hot filament the molybdenum wires are sealed directly into a piece of special glass (7) which has the same coefficient of expansion as molybdenum. The outer end (8) of the supporting tube is of soda glass like the bulb itself, and it is therefore necessary to interpose at (9) a graduated series of different kinds of glass to allow for the difference of expansion of (7 and 8). A small glass tube (10) surrounding one of the copper leads prevents short-circuiting of the copper wires (4 and 5). The tungsten filament which forms the cathode is heated by a current from a small storage battery, which should be carefully insulated from the ground. An ammeter and an adjustable rheostat in the circuit enable the heating current to be regulated with great nicety between 3 to 5 amperes. This range of current gives a potential drop through the filament of from 1.8 to 4.6 volts, variations of the corresponding filament temperature being from 1,890 to 2,340 degrees absolute.

The Famous "Coolidge" X-Ray Tube.



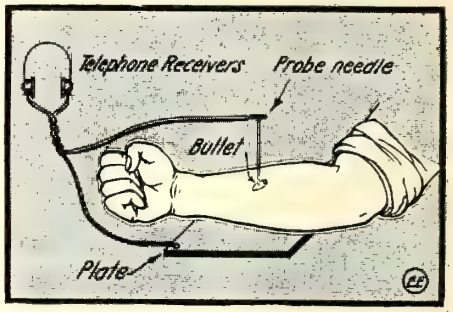
The focusing device consists of a cylindrical sleeve of molybdenum (11). It is mounted so as to be concentric with the tungsten filament, with its end projecting about 0.5 mm. beyond the plane of the latter. It is supported by two stout molybdenum wires (12 and 13) which are sealed into the end of the glass tube (7) (see Fig. 1). The sleeve is electrically connected to one of the filament leads (14). This, besides acting as a focusing device, also prevents any electron discharge from the back of the heated portion of the cathode. The anti-cathode or target (15), Figs. 1 and 2, also serves as an anode. It consists of a single piece of wrought tungsten welded to a molybdenum rod (16) of cylindrical section and supported by a molybdenum split tube (17). This split tube fits snugly in the glass anode arm (18) and serves the double purpose of supporting the anode and of conducting heat away from the cylindrical rod and so protect the seal of the inlet lead (19). The bulb is made of soda glass and is about 18 centimeters in diameter. The method of exhaustion is very long and complicated, and in the later stages of the exhaustion a very heavy current is maintained continuously on the tube for perhaps an hour, the temperature of the bulb being kept from rising too high by the use of a fan. The pressure in the finished tube is very low.

The main advantages of the Coolidge tube are the following: The quantity and the pentrating ability of the rays produced can be varied independently at the will of the operator with both ease and rapidity. When the tube is once adjusted to the requirements of the operator it needs no further attention. Both the intensity and the penetration of the X-rays are under the complete control of the operator. A higher penetration than can be obtained from any other tube is claimed, as well as a longer life. The tube can be worked off either alternating or direct current. Hence it is possible for an operator in actual practise to do all classes of work, ranging from that calling for the lowest to that calling for the highest penetration, with a single tube. Further, he can reproduce exactly what he or some other operator has done before. The adjustments are rapid and require the minimum of technical skill. It has been found that once the proper penetration and exposure had been determined radiographs of any object can be duplicated time after time with absolute precision.—*The Electrician*, London.

THE "KENOTRON" HIGH POTENTIAL RECTIFIER.

A new form of vacuum rectifier is described in a recent number of the *General Electric Review*.

When the electrically heated electrode in the bulb shown is cathode only a thermionic current passes. For a given voltage drop this thermionic current increases with the temperature, but above a certain temperature the current becomes constant. On the other hand, for a given temperature of the cathode the thermionic current increases at first as the positive potential on the anode is increased, but finally a saturation thermionic current is obtained and further increase in voltage has no effect. With a sufficiently perfect vacuum this thermionic current is due to a pure electron emission. The "kenotron" is a rectifier based on this

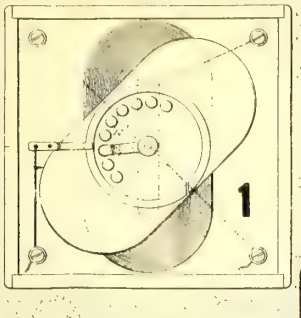


New Form of Vacuum Rectifier Tube.

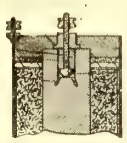
phenomenon, and the article discusses how the design depends on the amount of current to be rectified, the maximum permissible voltage loss and the proper form of electrodes to prevent electrostatic strains on the filament. Three different forms of kenotrons are covered. The first type contains a molybdenum cylinder and a coaxial filament and is suitable for alternating-current voltages up to 15,000 and a current of 400 milliamperes and voltages up to 100,000 and a current of 100 milliamperes. The efficiency of this rectifier is between 98 and 98.75 per cent. A second type of "kenotron," which is suitable for voltages not over 10,000 and currents ranging up to 100 milliamperes, contains a small filament such as is used in automobile head lamps inserted in a molybdenum cap about ⅝ inch in diameter. A third style is shown in our illustration. It contains a V-shaped filament between two tungsten plates.

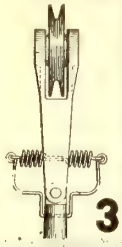
Hence this new form of rectifier promises to fill a number of engineering wants.

ELECTRICAL BULLET PROBING.



A new electrical method of probing for bullets is being employed in the military hospitals of Europe, says the *Lancet*, London. It consists of a head telephone receiver such as a sensitive wireless phone, together with a flat metal plate and a probing needle of the same metal. The patient's arm, for instance, is placed on the metal plate, which is connected to the telephone receiver, as is also the probing needle. When the surgeon touches the bullet with the needle there is formed a galvanic battery. This gives rise to an electric current which is heard in the receiver. Sir James MacKenzie Davidson says this method is undoubtedly more certain and easier to apply than the "induction balance," also in use for the purpose.





Locating Bullets with Telephone Receivers Only.

TESTS OF PERMANENT MAGNET STEELS.

J. A. Mathews has contributed to the proceedigs of the American Society for Testing Materials a paper based upon an extensive series of magnetic tests on steel alloys. The amount of permanent magnetism which hard steel will retain, and the tenacity with which it retains it, are profoundly affected by the heat treatment of the steel, as well as by its chemical composition. But different steels are affected differently by heat treatment. Some have their best permanent-magnet quality in the oil-hardened condition, while others —sixty hundredths per cent. carbon steel and five per cent. tungsten steel—are best when water-hardened. Thus, the "magnetic hardness" does not vary in the same way as physical hardness. Drawing the temper, however, reduces both hardness and magnetic permanence. In some steels, pieces of small section have greater permanence than larger pieces, while other steels have the opposite characteristic. The chief result of the tests made up to the present is that no uniformity of behavior is found among different steels, and that no laws or theories covering the phenomena can be deduced before a great amount of further experimenting has been done. The author found the best index of permanent-magnet quality to be the ratio between residual magnetism and coercive force. He proposes this ratio as a new magnetic unit.

A Brief Digest of the Latest Electrical Patents

WIRELESS TRANSFORMER (Fig. 1)—Compact loose coupler with pancake coils independently movable co-axially.

BATTERY CONNECTION (Fig. 2)—Improved dowel terminal for carbon electrode in dry cells.

TROLLEY WHEEL MOUNTING (Fig. 3)—Wheel is mounted with lateral thrust springs to give wider range of action, so it will not release its hold on trolley wire so quickly.

LAMP CONTAINER OR BOX (Fig. 4)—A simple carton to hold electric lamps while in shipment, etc.

HEAD-BAND ATTACHMENT (Fig. 5)—An extra flat plate secured to the head-band prevents band catching hair. A good idea and a boon to the telephone exchange operator.

ELECTRIC SIGN (Fig. 6)—Has bull's-eye lenses over each lamp, etc. Gives spectacular effect as liquid filling glass, etc.

MUSICAL DEVICE (Fig. 7)—Electrically operated striker for musical pipe, as shown.

PORTABLE ELECTRIC LAMP (Fig. 8)—Arranged with base attachable to anything. Socket also swivels.

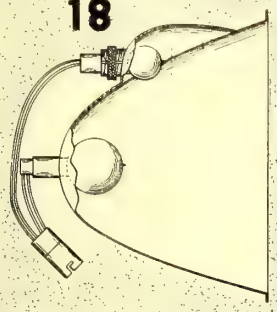
ELECTRIC SOCKET (Fig. 9)—Arranged with a pull chain and lever, acting on push button switch.

STORAGE BATTERY SEPARATOR (Fig. 10)—Ingenious insulating envelope to fit over battery plates and to separate them from one another.

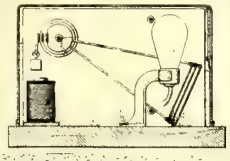
WIRELESS RECEIVER (Fig.) 11)—Magnet spool movable to or away from diaphragm by threaded thumb lever at rear, as shown.

TELEGRAPH RECORDER (Fig. 12)—Devised to operate on the sounder principle, the armature bar carrying a stylus, as indicated.

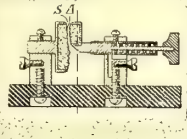
ELECTRIC HEATER (Fig. 13)—In the form of a cup to contain liquid and a food cup with perforated walls, held on heating element at center.



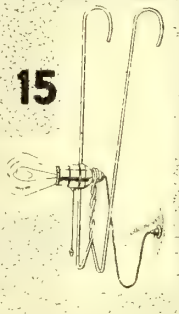
AUTO HEAD-LAMP AND SIGNAL COMBINED (Fig. 14)—Horn vibrator is mounted in rear of headlamp. Openings provided for efflux of sound. Tends to reduce the cost of auto manufacture, as both functions are combined in one chamber.



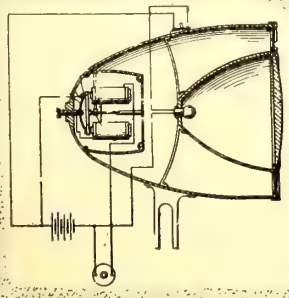
BEDSTEAD ELECTRIC LAMP (Fig. 15)—Provided with hooks to hang on bed rail. For reading.



NEW PICKARD RADIO DETECTOR (Fig. 16)—Uses silicon "S" and antimony "A."



CORNER-TURNING INDICATOR FOR AUTOS (Fig. 17)—Electro-magnet control operates sign frame arms, as perceived; signs appear before window with lamp behind them.



DUPLEX AUTO HEAD-LAMP (Fig. 18)—Good idea for providing small, city lamp in pocket at side of parabolic reflector, containing the regular head-lamp.

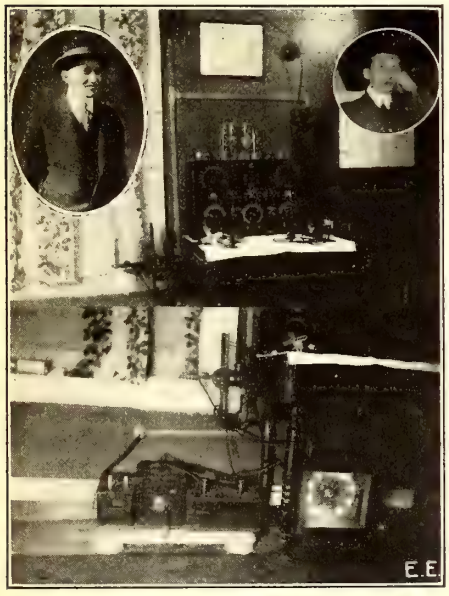
AMONG THE AMATEURS

Our Amateur Radio Station Contest is open to all readers, whether subscribers or not. The photos are judged for best arrangement and efficiency of the apparatus. To increase the interest of this department we make it a rule not to publish photos of stations unaccompanied by that of the owner. Dark photos preferred to light toned ones. We pay each month $3.00 prize for the best photo. Make your description brief. Address the Editor.

AMATEUR RADIO STATION CONTEST.



Monthly Prize, $3.00.

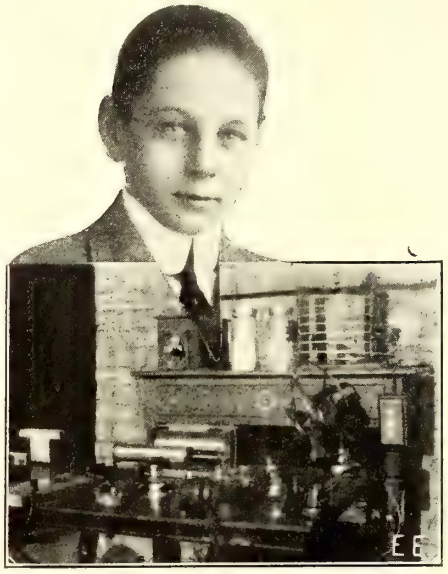
This month's prize winner.

WAYNE BROS. AMATEUR RADIO STATION.

Herewith are submitted photos of a wireless set, which may interest some of your readers. Before proceeding, allow me to say that this set is of entirely amateur construction, having been built by my brother and myself.

The photos show clearly the outer appearance of the set, but a brief description of the interior follows. I might first say that the receiving cabinet is entirely of hard rubber, and measures over all 20x12x10 inches. Contained within are a receiving transformer, loading inductance, and variable condensers. There are also the two sets of high-voltage batteries for the audions, and also the 1 to 1 ratio transformer for the amplifier. All coils are wound with stranded wire (or litzendraht) which much improves their efficiency, of course, for high frequency. The hook up of the set, which, so far as I know, is original with us, enables us to receive both damped and undamped waves with equal facility, and we have clearly

Messrs. Wayne Brothers and Their High-Grade Radio Set. Top: Receiving. Below: Transmitting.



heard on several occasions the high-powered stations at Berlin, Honolulu and San Francisco, which employ the undamped wave system for transmitting.

On ordinary spark sets, we have heard signals from Key West, Colon, and numerous ship sets, covering 1,100 miles in daytime; signals being from ships using the average transmitter employed on shipboard. We have also copied "press" from Poldhu, and have heard time signals from Arlington at a distance of 40 feet from the phones.

The transmitter is all home-made, and of one-half K.W. power. Transformer is

WEITH WIRELESS OUTFIT.

The following is a description of my wireless station, located at Chicago, Ill.: My receiving set comprises a double slide

Master Weith and His Radio Station.

tuner, variable condenser, fixed condenser, loading coil, battery, potentiometer, galena and also a silicon detector, 1,000-ohm phones and a high note buzzer for testing the detectors. The receiving set is on the bottom part of the table; all necessary switches are used.

My sending outfit is composed of a ½-kw. transformer which runs on the 110-volt circuit. Leyden jars, spark gap, key and oscillation transformer. The sending set is on the top part of the table, except key.

The aerial is 50 feet long and 100 feet high and consists of two wires. I get very good results with this set.

ROYAL C. WEITH,

Chicago, Ill.

of open core type and employs a choke coil to regulate current. Referring to the photo: To the left may be seen the impedance. In the center is the transformer, and to the right the condenser, which is of glass plate type, immersed in oil. The oscillation transformer, which is of the double sliding pancake type, is secured to the table.

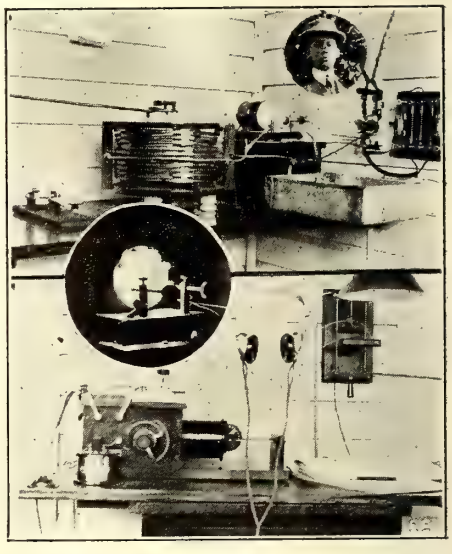
The rotary gap is of the Marconi type with rotating bar, carrying the two electrodes instead of the usual pin-wheel type. This gap has the advantage of starting quickly, and also keeps cooler than the wheel gap. Also the glass-front case containing the rotary is suspended by four spiral springs, which reduce the vibration of the motor to a minimum. We have transmitted 50 miles.

MONROE WAYNE,
A. ROSS WAYNE

New York City.

The most efficient way to recharge small storage batteries is by means of a small dynamo driven by water motor or gasoline engine.

RADIO STATION OF RAYMOND MYERS.



Below is shown the radio equipment of Raymond Myers, Tiffin, O. The sending set consists of Blitzen ¼-kw. transformer, oscillation transformer, rotary gap and an oil-immersed glass plate condenser. The receiving set includes a navy type receiving transformer with dead end switches, Murdock variable and fixed condensers, galena detector and Brandes' 2,000-ohm phones. The aerial is 40 feet high and 120 feet long, composed of four antenium wires on 11-foot spreaders.

With this outfit I have heard all of the near-by lake stations and a great many along the Atlantic Coast south to NAX. Have picked up amateurs this winter from Buffalo, N. Y., to St. Louis, Mo., a few being 8KP, 8BC, 8EG, 8OZ, 9EE, 9EG, CHW, 9BD and have heard 9YN on several occasions. In sending I have been heard 200 miles away and talked with a score of amateurs within a radius of 75 miles. Time and weather reports are received daily at this station from NAA and NAR, and with loading inductances connected in circuit WSL clearly responds.

A Radio Club has been organized in this city, and I would be glad to hear from any amateurs who would like to join. I have a Government radio license (second-grade amateur), and my call letters are 8CT.

RAYMOND MYERS,

Tiffin, O.

Top Photo Shows Mr. Myers and His Sending Set. Center: Rotary Gap. Below: Receiving Station.

TECH WIRELESS CLUB NAMES NEW OFFICERS.

The Tech Wireless Club of Harrisburg, Pa., has elected these officers: President, Prof. Peet; vice president, Prof. Loomis; secretary, Charles Everett Kutz; treasurer, G. Webber Knight.

Besides some minor pieces of apparatus the club will add a new aerial to its equipment this year. The aerial will be in the shape of an angle, one side of which will be seventy-five feet and the other side sixty feet. The apparatus will be greatly increased in strength and the members expect to get into communication with Lehigh University.

ROCKWELL RADIO LABORATORY.

It certainly is a great idea to incorporate in your fine magazine, *The Electrical Experimenter,* such a contest as the "Amateur Radio Station Contest" is bound to be. Enclosed you will find a flashlight of my wireless and experimental station, and also a photo of myself, which I wish to enter in this contest.

In my receiving circuit I have a loading coil, an E. I. Co.'s loose coupler, a variable condenser, a blocking (fixed) condenser with controlling switch; a potentiometer which controls the current to my E. I. Co. electrolytic detector, and also to my carborundum detector; an E. I. Co. Universal detector stand, using galena with two 2-point switches to throw in either detector with or without potentiometer; a Junior fixed condenser across phones with controlling switch, and 3,000-ohm phones.

On my sending side, I have a 1-inch spark coil which is operated by a transformer which reduces the street alternating current down to eight volts; an E. I. Co. wireless key; a zinc spark gap, sending Helix and a Leyden jar condenser.

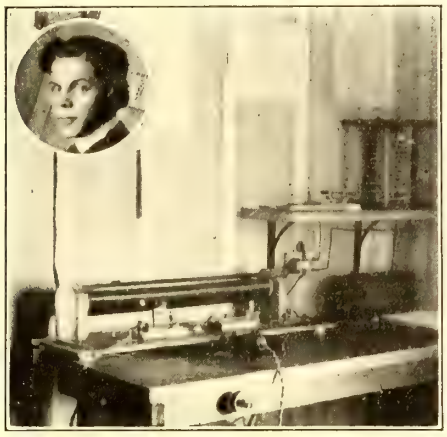
Left: Donald P. Rockwell.

Below: His Complete Wireless Sending and Receiving Apparatus.

My aerial is of No. 14 wire, about 120 feet long, of 4 strands, 60 feet high at one end and 40 feet high at the other end.

My ground is a ¾-inch pipe driven 8 feet into the ground. The receiving set has a range of from 1,200 to 1,500 miles, and the sending set a range of from 6 to 8 miles.

In my station I have, besides my wireless set, a telephone and a telegraph, both of which I use in communicating to different friends about the city. In the telegraph circuit I have a sounder, a relay and a key. In the telephone circuit is a receiver and a Stromberg-Carlson transmitter.



DONALD B. ROCKWELL,
17 Walnut St.,
Wellsboro, Pa.

The efficiency of wireless transmission over long distances is very low owing to the scattering of the waves in all directions. Probably the average energy received from a transmitting station is but one one-millionth part of the initial power radiated.

RADIO INSTALLATION OF J. L. TAYLOR, JR.

I have an efficient wireless station and give you a photo of same, as well as one of myself.

The receiving set consists of double slide tuning coil. Universal crystal detector, Murdock loading coil, 8-point variable fixed condenser and Murdock 1,000-ohm single headset. I also have buzzer test. I hear N. A. A., W. C. C., N. A. D., W. S. L. and many other nearby radio stations.

Mr. J. L. Taylor, Jr., and His Radio Station.

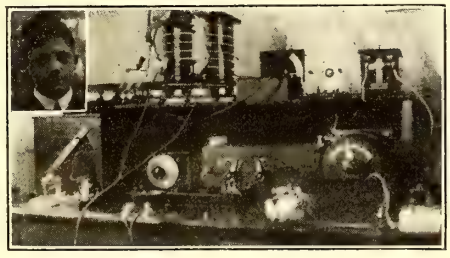
My sending set consists of Mesco key, 1-inch spark coil, spark gap, suitable condenser and oscillation transformer.

Aerial is 65 feet long, consisting of four wires spaced two feet and supported by pole 50 feet high. Lower end of aerial is about 30 feet high and fastened to roof of house.

The ground is an iron pipe driven into ground about seven feet.

I have an amateur's license and also station license. My call is "8 W. S." On the whole, I am quite pleased with my set.

I read the *Electrical Experimenter* and enjoy it very much.



J. L. TAYLOR, JR.
Barker, N. Y.

PALMER HILL'S AMATEUR STATION.

Below is a photo of my wireless station, which I would like to enter in your wireless station contest.

The sending apparatus consists of a one-inch spark coil, rotary gap, home-made condenser and helix, key and hot wire ammeter, also a rheostat for gap.

Receiving set as follows: Clapp-Eastham and E. I. Co. loose couplers, large, home-made loading coil, fixed condenser, switch box, loading inductance, Var. condenser, galena detector and others for experimenting with different substances, aerial switch and Government receivers.

Palmer Hill's Excellent Wireless Outfit.

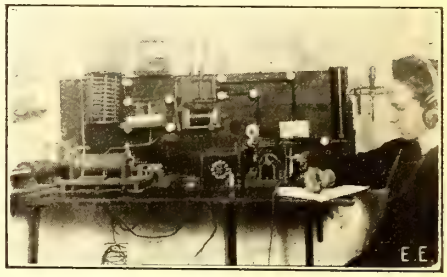
Most of the instruments are of standard make, which I find very efficient. The aerial is 50 feet long, composed of six wires, 40 feet high, of the inverted "L" type. I am going to erect a six-wire aerial 300 feet in length for receiving purposes.

I hear all the coast stations from N A B to N A R; also, on Friday, Jan. 8, 1915, between 9 and 10 p. m., I heard wireless telephone messages and music.

PALMER HILL.
Stamford, Conn.

C. L. Robinson, of Laquey, Mo., writes us as follows:

"I received the April *Electrical Experimenter* which I wrote you about and thank you very much. I am very much delighted with your magazine. I have read several but it is the best I ever saw for the general Electrical and Wireless Experimenter. Success to you."



FLINDT STATION.

The following is a description of my radio station:

Transmitting: One and one-half inch spark coil run on eight dry cells, volt and ammeter for testing, wireless key, Helix and spark gap. I use a high-tension glass plate condenser; wave meter for regulating wave length. I have a range of 10 miles with this apparatus.

Receiving: Loose coupler with variable condenser across primary. I employ a condenser and detector in secondary circuit. Phone 2,000 ohms resistance.

A loading coil is in series with aerial.

Radio Messages "Coming in" at Walter Flindt's Station.

Double-pole, double-throw switch connects either sending or receiving circuit. My aerial is 80 feet long and 60 feet high with four wires. Have caught stations as far as 800 miles away at night.

WALTER FLINDT.
Philadelphia, Pa.

NEW AMATEUR RADIO STATION AT GARDINER, ME.

The new wireless station installed by F. H. Woodbury, was given a tryout recently and worked perfectly. Many messages were picked up from incoming ships and places all along the coast and the receiving apparatus worked exceptionally well.

Considerable credit is due the men of the Central Me. Power Co., who did the work of establishing the aerials. The work was made difficult because they are stretched from two poles fastened on the peaks of two buildings with slanting roofs of slate that made the work somewhat hazardous as well as difficult. One expert who has seen similar installations says that it is one of the best jobs he ever saw. It is the efficient way in which this work was done that is largely responsible for the perfect working of the apparatus, undoubtedly.

The prime object of the apparatus is to get the correct time from Washington.

QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

RECEIVED RADIO ENERGY.

(273) Ralph L. Kunau, Sabula, Ia., asks several radio questions.

A. 1. We would suggest that nothing smaller than No. 16 B. & S. conductor, either solid or stranded, such as lamp cord, should be used in wiring up a radio receiving set. No. 22 to 24 B. & S. wire is used considerably for tuning coils.

The voltage of a received current on a wireless aerial over medium distances where the signal is strong is of course very minute. It is probably on the order of one hundred-thousandth of a volt. Under ordinary conditions, using a crystal detector with high resistance head phones, etc., the current necessary in the aerial for good, readable signals is about 40 micro-amperes. Signals are rather hard to read when the current drops as low as 10 to 15 micro-amperes. Of course, when amplifiers are used, the current may be many times weaker than here mentioned, and the signals will still be readable. An experimental potentiometer may be made from a pencil as you suggest.

WAVE LENGTH MEASUREMENT.

(274) Mr. S. H. H——, Cleveland, Tenn., sends several radio wave length queries.

A. 1. In regard to your aerial wave length and your wave meter, etc., would advise that as long as you have a wave meter of the Clapp-Eastham type you should have no trouble in finding out just what adjustments you have in your circuits as to wave length values, etc.

After looking over your question carefully, it appears that either the capacity or the inductance in the closed oscillating circuit must be reduced, if you are to radiate energy at 200 meters wave length. We believe that in your second case that the wave meter has been placed too close entirely to the excited system of the aerial. This, of course, would account for the fact that you could hear the signals in the wave meter receiver all over the condenser scale. In using the wave meter in every case, it must only be placed just close enough to the wireless transmitting set so that the faintest signal can be heard nicely at the point of maximum resonance in the wave meter. This point is found by turning the condenser handle back and forth.

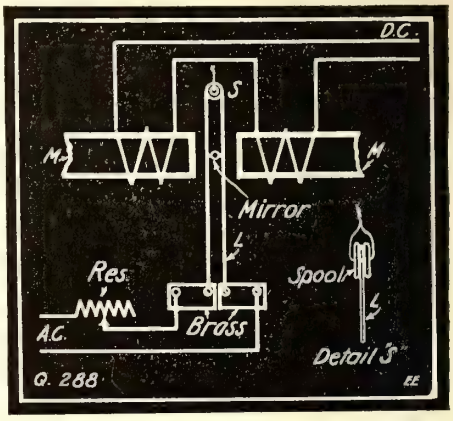
The editor of this column, from some experience in the matter, always prefers when possible, or when tuning transmitter sets, to make use of a small low-voltage battery lamp or a small Geissler tube connected across the condenser terminals of the wave meter as a resonance indicator in place of a telephone and the detector. Undoubtedly, when you get your two oscillating circuits properly joined together or in perfect resonance, you will be able to transmit 80 to 100 miles easily with your 12-inch spark coil and electrolytic interrupter.

RADIO QUERIES.

(275.) Rudolph Fehnle, Moballa, Ore., asks the question department several radio questions.

A. 1. A double head-phone set is always preferred to a single receiver, as the joint action of two 'phones acting on both ears simultaneously gives a much better effect acoustically than when only one is used.

When tuning coils are used for loading purposes they are simply connected in series with the aerial lead-in, one wire being joined to the end of the coil proper and the other wire to one of the sliders.



We do not suggest sand-papering enameled wire on tuning coils, except where the slider is to make contact. The capacity effect of enameled wire insulation is of small import, generally speaking.

OSCILLOGRAPHS.

(275 A.) Oscar P.——, 825 Roscoe street, Chicago, Ill., is interested in the operation of an oscillograph for tracing the curve of alternating wave form, time-circuit values, etc.:

A. 1. The sketch shows simply how the oscillograph works, and the current of which a record is desired is passed through the looped wire shown, which is supported in a powerful magnetic field, produced by direct current excited magnets MM.

The looped wire L can be of fine platinum (say .0005" dia.), and it passes around a small spool-shaped suspension, as sketch shows, the spool being hung on a fine quartz fiber preferably. Between the wires is supported a miniature metallic mirror, which reflects a beam of light on a moving strip of photographic film. After a record has been taken the film is developed as usual. The film compartment is, of course, light-tight and the fluctuating current passing through the loop L causes the moving mirror to trace a line of the wave form, etc., on the moving film. A suitable resistance should be connected in series with the element L, of course.

The Principle of the Oscillograph.

It is possible to build one of these machines cheaply with a little care, but the commercial machines are rather expensive and generally cost in the neighborhood of several hundred dollars.

Want to Swap?

If you have anything to buy, sell or exchange and want to make sure of doing it quickly and at an insignificant cost advertise in the

Scientific Exchange Columns
OF
The Electrical Experimenter

You will find advertised in these columns:

Photographic supplies, Phonographs, Wireless Apparatus, Electrical goods, Bicycles, Motorcycles, Rifles, Gasoline Engines, Microscopes, Books, Skates, Typewriters, Etc.

The owners of these things wish to ***"swap"*** them for **something else, something which you may have.**

The Rates

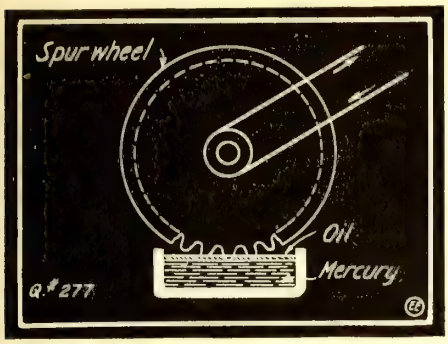
The Classified Columns of the ELECTRICAL EXPERIMENTER GET RESULTS

More than 30,000 Electrical Experimenters will see your ad.

WATTMETER HOOK-UP.

(276.) James W. H.——, New York City, wants connection diagram for Weston type direct-reading wattmeter in a wireless transmitting circuit.

Watt-Meter Connections in Radio Transformer Circuit.



A. 1. Diagram is given herewith for connecting a direct-reading wattmeter in on 110-volt A. C. wireless transmitting sets.

LODGE MERCURY COHERER.

(277.) Sumner B. Young, Dorchester, Mass., inquires as to the construction of the Lodge mercury coherer:

A. 1. In the mercury coherer of Lodge's pattern a toothed wheel is caused to rotate by clockwork, etc., over a small mercury pool. Over the mercury is placed a thin film of oil such as machine oil, and the coherer is so adjusted that the teeth of the brass wheel just barely touch the mercury. The sketch shows the arrangement of this device in this case.

The incoming etheric wave currents break down the slight insulating film between the teeth on the wheel and the mer-

The Lodge Mercury Coherer.

cury, thus allowing more battery current to pass through the coherer to the signaling instrument. The oil helps to restore the coherer to its normal state. This coherer is therefore "self-healing."

TOPOGRAPHY VERSUS WIRELESS.

(278.) F. W. Noel, Boswell, Pa., asks us about height above sea level in respect to wireless work:

A. 1. The height of your location above sea level has no appreciable effect on radio operation, generally speaking. What we mean to say is that persons living at very high altitudes and those living in valleys several thousand feet lower use practically the same aerial dimensions. It is considered best, however, when a choice can be had, to erect the aerial on the highest point of land available.

You should be able to get the Arlington Time Signals at your location, 200 miles from Washington, with a good receiving outfit, providing your aerial has a fair length. The length should be preferably from 100 to 150 feet, but you may try your 55-foot length aerial before increasing same if desired.

TELEPHONE RECEIVER NEEDS REMAGNETIZING.

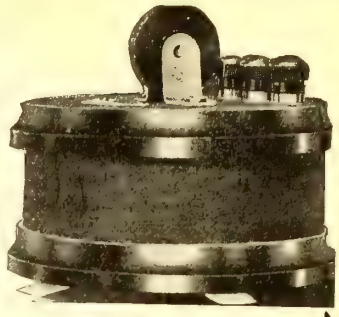
(279.) Philip C. Platt, Bridgeport, Conn., writes regarding a telephone receiver which has apparently become demagnetized:

A. 1. Most probably you had best return the receiver, which has its magnets weakened, to the makers for remagnetizing.

A. 2. Rotary spark gaps are used a great deal with spark coils, but unless some synchronous form of interrupter or commutator is used in connection with the rotary gap it is very difficult to get a pure tone from the outfit. Quenched spark gaps are generally found best for use with spark coils, no matter whether the coil is interrupted in the primary circuit by a vibrator or electrolytic interrupter. The above consideration will be evident to you very plainly upon analyzing the action of such interrupters, which is very unsteady or variable as to frequency.

LOOSE-COUPLER SWITCHES.

(280.) William Neckerman, West New York, N. J., wants to know how switches can be connected to loose-coupler primary so as to cut out one of the tap switches where desired:



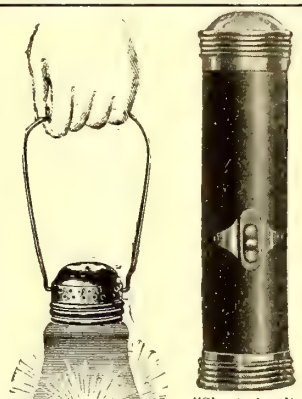
A. 1. You can divide up the winding as you mention on the large loose coupler and simply place a two-point switch "S," as shown in diagram, to quickly cut out about half the winding or other parts of it in one step as desired for rapid change of

EXTRA SENSITIVE
EXTREME DISTANCE

MORE SENSITIVE THAN EVER

CRYSTALOI—Type AA

A PERMANENT WIRELESS DETECTOR THAT HAS MADE A WONDERFUL RECORD



DIMENSION 4" x 3½".

This, our latest type of **Crystaloi Detector** contains a new *cohering inductance* and new formular of alloy which cuts down the internal resistance of the Detector, makes it much more sensitive and improves the general efficiency about 50 per cent., which naturally increases your distance. This new type of **Crystaloi** is a handsome instrument of hard rubber composition, trimmed with *German silver*. It is provided with three binding posts and anti-shock feet. **ORDER ONE TODAY** and add to your set the **greatest of all Wireless Detectors.** Full information on request. Our new miniature wireless catalog on receiving apparatus describes many new wireless instruments. A Post Card will bring one.

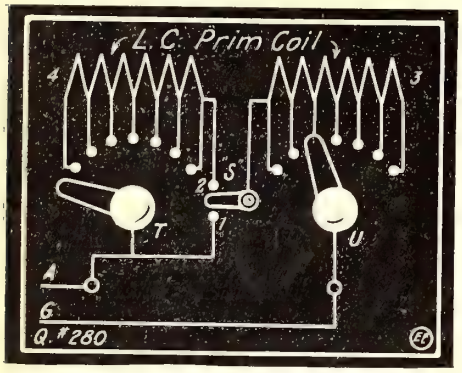
Best Paying Branch of the Dental Profession

STUDENTS CAN EARN within a very short time $30 to $100 per month while learning.



The demand for mechanical dentists far exceeds the supply. Prof. Bodee, the most ingenious and thorough mechanical dentist in America, gives every student personal instruction. Established 1892. The first and only school recognized by the Dental Profession. Not a correspondence school. Practical work and individual instruction; no book study. Tuition payable in moderate monthly installments; complete course 2 to 6 months. Students received at any date without entrance examinations or previous schooling. Anyone can learn. Write to-day for catalog E.

BODEE'S DENTAL TRADE SCHOOL Now in our new building 15 West 44th St., New York

wave length. By the arrangement here shown you also gain a great deal, as when the switch "S" is on point 1, and switch

Switching Scheme for Loose Coupler.

"T" is opened or placed on the dead point, there will not be an undue loss from distributed capacity in the idle turns of the coil.

INDUCTION COILS ON A. C. TRANSFORMERS.

(281.) Frank S. A.— —,Easton, Md., states he cannot get his induction coil working right on a step-down A. C. transformer:

A. 1. We do not know how you are attempting to use your spark coil in connection with the small A. C. transformer of the step-down type.

However, we may state that in every case such as this the spark coil vibrator is, of course, used the same as if a battery were employed. Otherwise you will get no results at all, as the low voltage A. C. has too smooth a sine wave form to give any results in the spark coil, and the vibrator must be used to give a sharp break in the circuit.

The statement you make is incorrect regarding the passage of an alternating current through any coil which has an iron core within it. Any transformer ever used, practically speaking, has, of course, its proper iron core, and alternating current is used in all of these transformers throughout the country for lighting and power work, for wireless stations, etc. The current in the ordinary spark coil, using batteries for excitation, is really an unsymmetrical alternating current, as has been proved by oscillographic tests in the laboratory.

DICTAGRAPHS FOR DEAF PEOPLE

(282.) E. I. C.——, Lexington, N. Y., writes us regarding a special model dictagraph which he has purchased for helping him to hear better, and which does not help him as expected:

A. 1. The editor of this column has known of a number of such cases and, in fact, has been personally familiar with a couple of cases where such instruments as the dictagraph did not prove of benefit at the first trials of same. This is due probably to the fact that such an instrument gives forth rather a harsh sound in reproducing the speech at first to a person who has never heard it in operation before; therefore speech is not always fully intelligible. We believe, however, if you try this instrument daily for a week or more that you will soon become accustomed to it and that it will help you. Most companies do not, however, make any positive guarantee at all that this instrument will absolutely in every case help those hard of hearing to hear perfectly. This is because every case of deafness or partial deafness

DO YOU KNOW HOW TO—

Figure the number of turns of wire required for the primary of a transformer of any size?

Design and build a magnetic leakage transformer?

Build an induction coil to give a heavy, 1-inch spark with only a pound of wire in its secondary?

This Book at 25 cents will tell you how.

New Revised Third Edition.

CONSTRUCTION OF INDUCTION COILS AND TRANSFORMERS

By THOMAS STANLEY CURTIS.

Contains information hitherto unpublished in book form, written for the amateur in plain English; practical instructions for building high-and-low-voltage, magnetic leakage, high frequency, and other special transformers; interrupters, condensers, gaps, etc. Also chapter on high frequency experiments.

Sent Prepaid on Receipt of Price.

CHEAPER ELECTRIC VEHICLES.

A new style of electric vehicle has been developed by a New York engineer, it is said, which will make possible a large reduction in the cost of same. Dr. C. P. Steinmetz said recently of this new design, "that it held great promises. Among other unusual features this electric auto has no differential gear, but a divided motor, in which the field and armature both rotate, each driving one rear wheel. Electric braking is utilized, and arrangement is made to permit the motor acting as generator to partially recharge the storage battery when running down hill. Twice the power ordinarily realized is obtained owing to the field and armature both revolving, thus reducing the size of battery required."

BARON MÜNCHHAUSEN'S NEW SCIENTIFIC ADVENTURES.

(*Continued from page 43.*)

me, while tears of gratitude ran down his ruddy cheeks. We then discussed the details, and next morning we put the whole plan before the Government. The President and his Cabinet, General Sir John French, of the British army, as well as King Albert, of the Belgian army, were even more enthusiastic than Joffre had been, and a vote was passed immediately authorizing me to go ahead with the work.

"So cautiously did we proceed that no German spy ever got wind of the great scheme. No suspicious character was allowed to come within 10 miles of the tunnel openings and, as the latter were cunningly started under large railroad sheds, reconnoitering aeroplanes of the enemy never suspected what was going on beneath.

"There were four large tunnels all told. The first started at a point near Pont-à-Mousson, ending in the forest of La Fourasse. Another one started not far from Verdun and ended in the forest of the Argonne. No blasting or dynamite was used for fear of arousing the Germans overhead; each tunnel was large enough to enable 20 men to march abreast in it upright.

"At the end of December, 1914, we had over 150,000 men at work on the four tunnels, and by February 1, 1915, they were completed except for a few yards at the far end. During that night the entire French as well as British and Belgian armies walked into the tunnels—men, horses, automobiles, artillery and all. We had burned our bridges behind us; everything was staked on the *grand coup*.

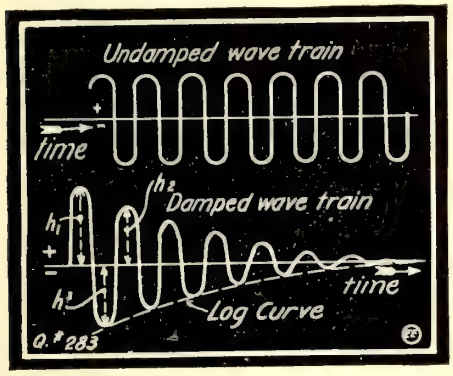
"A small opening was then made carefully at the end of each tunnel, and one of our men cautiously emerged through each small hole. Each of the four reported the forests quiet, whereupon our sappers quickly broke out a large opening; within one hour our armies began to *debouche* from the tunnels, and by morning the four units had marched out of the four forests. One-half of the armies were to fall into the backs of the Germans and the other half were to march on Berlin. I was with the latter, highly elated at our success. We immediately seized all railways and roads, and our advance began.

"There was only one thing which disturbed us. By night we were informed that the other half of our legions which were to fall into the back of the enemy had failed to find a single German soldier. Neither Joffre nor I could understand this, but the next morning we had the glad tidings that our army had taken some 40,000 prisoners and that not a single German remained. Joffre and I naturally reasoned

(*Continued on page 73, second column.*)

(*Continued from page 72.*)

is different, and some require surgical or other treatment.



DAMPED AND UNDAMPED WAVES.

(283.) Blair Mudgett, Johnstown, Pa., asks for explanation of damped and undamped radio wave phenomena:

A. 1. The curves here shown will give you an idea as to what is meant by the damping of radio waves. As you will perceive, these waves gradually but surely fall off to zero amplitude. This considers, of course, a damped or spark wave, and not an undamped wave, such as that developed or produced by an arc generator, for instance.

The damping of the waves as here outlined takes place in accordance with the rule of logarithmic decay—that is, the peaks of various successive waves or positive and negative ripples follow a logarithmic curve as perceived from sketch.

By logarithmic decrement is meant a certain amplitude value of one successive wave as compared with the preceding. The Government radio law now in effect stipu-

Difference Between Damped and Undamped Wave Trains.

lates that the ratio between the amplitude of the first wave and the second half wave following it shall not exceed 2-10 when these two amplitude values are compared with a Naperian logarithmic base. In practise this logarithmic decrement is always found with a decrementer such as the Marconi or Kolster type.

The logarithmic decrement in Germany and the United States considers the value of decrement as equal to the Naperian logarithm of the term (height of wave h1 divided by height or amplitude of wave h2). In England the decrement is expressed as Nap. log. of h1 divided by the next half wave amplitude h3. Hence the U. S. value is found by multiplying the English text-book value by 2.

A log. decrement of .2 is equivalent to 12.5 waves in the train before the amplitude "h" falls below one-tenth of the maximum. Good tuning cannot be done if there are less than about 15 waves in the train. Hence the law stipulates a decrement of not more than two-tenths.

THE SEPARATION OF STEEL AND COPPER FILINGS.

Put some fine copper and steel filings on a piece of paper. By passing an electric spark from an induction coil through them the filings will be found separated. Arrange very fine copper filings on a sheet of paper. It will be found that one electrode only will attract the copper filings, the other electrode remaining inactive. If for copper filings we substitute powdered plumbago on glass we shall find a decided repulsion ensuing.

(*Continued from page 72.*)

that the Germans had held their western trenches largely by bluff, while their real army, consisting of several million soldiers, had been thrown against the Russians to hold the latter back from East Prussia and their new invasion of Hungary.

"We therefore pressed forward with great speed, using Germany's wonderful strategic railroad system for the main advance.

"On February 5 our allied armies had crossed the Rhine at Cologne, Koblenz and Mayence. On February 10 we crossed the Weser, and on February 20 we entered Berlin triumphantly, without a shot having been fired. It was almost too good to be true, but more work lay ahead of us. Our mission was only half filled. We had not as yet conquered the main German and Austrian armies, which we knew to be on the eastern frontier, and no victory can be complete as long as a powerful army remains in the field. In accordance with this, we began pressing forward again, when we were dealt a most terrible shock.

"We received the awful intelligence from our army which we had left behind (in order to patrol the conquered territory) that one and one-half million Germans were rushing on us with forced marches *from France!*

"We were dumfounded. Was it a trick or a hoax?

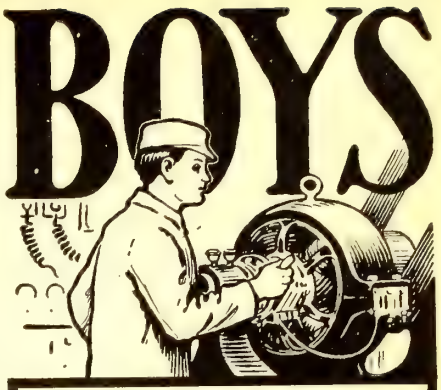
"Alas, it was neither. I will not bore you to death with a most unfortunate, heart-rending tale. This is what happened:

"Some German had hit upon the same idea as I had, but instead of boring four tunnels they bored but two. That was the only difference! While we thought we emerged behind their backs, they thought they were doing the same thing in reference to us. By a strange coincidence they marched out of their tunnels during the same night as we marched out of ours *and, while we captured Berlin, they captured Paris and then Bordeaux!*

"Not finding our armies (which they thought had retreated into the interior), they feared a trick and rushed back till they came upon the other half of our army stationed along the Rhine. Then they knew the truth.

"A curious state of affairs had, therefore, arisen in this terrible mix-up:

"We held Germany and a part of Austria, while the Germans held nearly all of France! Neither of us had gained any advantage, so we called a truce and agreed to trade back our present trenches for our former ones, while they agreed to take back theirs.



"For this reason March 1, 1915, found us in exactly the same position we had left on February 1, 1915, with the difference that for two days the Kaiser had been in Paris, while Joffre and I had been in Berlin!

"I immediately fell in disgrace with the Allies and I thought it best to take myself out of the way, which I did."

Baron Münchhausen took a long breath at this juncture, so I commented:

"This is certainly a most remarkable story; but, my dear Baron, how is it possible that we have never heard a single word about this momentous phase of the war? No newspaper ever mentioned a word about it, to the best of my knowledge. How can you explain that?"

"My dear boy," Münchhausen replied wearily, "evidently you have not been in Europe during the war. The explanation lies in the one word: Censorship! The Allies while marching on Berlin allowed no news to leave the country for fear that the German and Austrian armies at the Russian frontier would hear about it too early, so they naturally kept quiet."

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large—promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy. See your parents about it—they want you to succeed.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

Circular sent on request.

"But, your Excellency," I broke in, "how could that have helped you? As you advanced from town to town in Germany the Germans certainly must have had plenty of time to send word ahead by telegraph to their armies at the Russian frontier that the Allies were advancing on Berlin. This does not look right, somehow."

Baron Münchhausen chuckled softly for some time before he replied:

"Ah, my boy, I knew you would ask this, so I kept it until the last. The failure of the Germans in the East to receive news of our invasion was entirely due to a brilliant ruse of mine, studied out long before our entry into Germany. Like all my successes, this one was the simplest of them all. Ridiculously simple! I must laugh every time I think of it!

"You see, when the Allies emerged from the forests that night they were all of them, down to the last soldier, *attired in German uniforms!!*

"As large bodies of German soldiers were thrown back and forward over the great German railroad system so often during the war no one thought anything of our invasion, thinking us, of course, as Germans all the while; as a matter of fact, *over 80 per cent. of the German population never knew that the Allies had invaded Germany and Austria until we were back in our own trenches in northern France and Flanders.*"

Here Münchhausen indulged in an uproarious laugh before he proceeded:

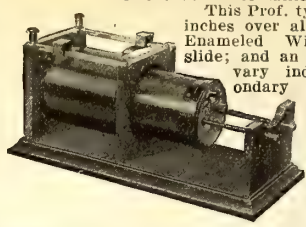
"The fortresses which we encountered had so few men that we did not even bother to take them. Had the defenders found out during our advance on Berlin that we were not their compatriots they would have been powerless, as their numbers were pitifully small as compared with the immense armies of the Allies. However, they never suspected us. As we had naturally taken charge of all the telegraph and telephone lines immediately upon emerging from our forests, we sent, of course, fake war reports to Berlin all day long purporting to come from the front. The deception could not have been more complete. So you can readily see that all the 'news' which the Nauen wireless plant sent out broadcast each day over the entire world during the month of March was nothing but a hoax, manufactured expressly for it by our own General Staff!"

I was so stunned by this revelation that I sat speechless for a few seconds. But I collected my thoughts suddenly, and demanded:

"That is all good and well as far as it goes, but what about the German army in France, my dear Baron? How could over a million Germans have taken Paris and Bordeaux without the outside world hearing about it?"

I thought surely that I had cornered Münchhausen that time, but he merely gave a deep sigh and said sadly:

"Alas, great minds always run in the same channels. That German who thought of digging the tunnels underneath our troops also thought of putting *his* soldiers *into French and British uniforms!!*



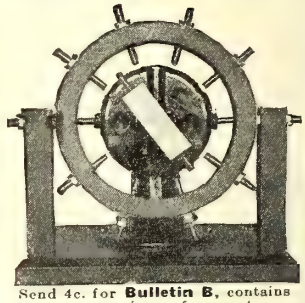
"So, you see, the German masqueraded armies fooled the French population precisely in the same manner as I fooled the German people with mine. There are thousands of French even to-day who have not the slightest knowledge that Paris or Bordeaux had been actually in German hands!! Think it over, and you can reason it out yourself how it worked. . ."

"And what did you do next, your Excellency?" I asked, more or less apologetically, for having doubted the Great Man's word.

"My last experience with the Allies having proved so humiliating to me, I did not wish to show my face in Europe any longer,

INDUCTIVE TUNER

There Is None Like It.



This Prof. type Tuner, 7x7x15 inches over all, is wound with Enameled Wire, has double slide; and an 8-point switch to vary inductance of secondary winding. Price, $7.00.

Parts of this Tuner, unassembled; wood work stained, tubes wound, taps made, etc., $5.50. Our latest catalogue has 64 pages, and over 100 illustrations: and deals entirely with Wireless Telegraph Apparatus.

You should note our Rotary Spark Gaps. Also parts of same sold separately, if desired. Everything else equally interesting, especially prices. Send 5 cents in stamps for this large new catalogue B-B-24. Positively none sent otherwise.

F. B. Chambers & Co. 2046 Arch Street, Philadelphia, Pa.

HIGH TONE ROTARY RUNS 8,000 R. P. M.

Gives 600 cycle whistling spark like a quenched gap. Attains full speed in 1 second; stops dead inside of 3 seconds.

You do not have to wait for this Rotary to start nor do you have to wait for it to stop. It always beats you to it.

The light revolving discharger arm allows a quick start and quick stop.

Will work on sets up to 1 K. W. Used on 60-cycle current.

Send 4c. for **Bulletin B,** contains many new pieces of apparatus.

Price, $12.50.

Yes sir. I have smashed typewriter prices right and left, and I guarantee to sell you a machine for less money than anyone else. I am the largest rebuilt typewriter buyer in the United States.

500 MACHINES AT $10 TO $15

Do not pay 20 to 40 per cent more when you can buy from me. Rebuilt typewriter prices have advanced tremendously, but I still stick to the same prices.

All Machines Guaranteed For 3 Years

When you buy from me, you get a guarantee to keep the machine in repair for 3 years. Write for **FREE** descriptive circular.

"Spot Cash" Gaerte, Pres.

Dearborn Typewriter Exch., Dept. 62A Chicago

so I decided to come to America, where I arrived in the middle of March. Having been in America previously, the country was not new to me; as a matter of fact, I had acquired some years before a large estate on the south shore of Long Island. To this I retired and, not having many friends in the neighborhood, no one bothered me much and I shortly completed my inventions on which I had been experimenting in Paris and which the war brought to an abrupt termination, as mentioned to you before.

"The problems of gravity had long attracted me most powerfully. With Newton, the famous, I wondered what made an apple fall from a tree or a brick from a roof. Newton long ago, in his famous works, had told us the *why*, but he had died without knowing the *how*. He knew all the laws governing gravity, but he knew not what the force consisted of. He was very much like Edison, who knows a great deal about electricity and its laws, but who does not know what electricity itself consists of.

"It did not take me a long time to actually solve the mysteries of gravity, once I hit upon the right track. I found that gravity, like electricity, is a certain manifestation of the luminiferous ether which permeates the universe and all matter.

"Once I had solved the mystery I set out immediately to find an insulator for gravity, and in a few days I had solved this problem in a masterful manner.

"To make myself plain: On earth all objects are attracted to the center of the earth by the force known as gravity. Whether it be a cannon ball or a feather, both will fall on the earth's surface if unsupported. If some means could be found to interpose between a falling apple and the earth a 'gravity' insulator, through which gravity could not act, the apple would stay suspended in mid-air, theoretically. It could not fall to the earth because there would be no longer any gravity to attract it.

"A parallel to the above is found in the following simple experiment: Take a steel ball and rest it on a smooth surface. Then take a strong horseshoe magnet. With it approach the steel ball; as soon as the magnet comes close enough the ball will roll toward the magnet till it reaches it. Separate the two again and repeat the performance, but before the ball reaches the magnet interpose a magnetic 'insulator' between ball and magnet—in this instance a stout piece of sheet iron. The iron will take up all the magnetism and no magnetic flux will reach the ball. Consequently it will lay still, unaffected by the strong magnet, which is just as strong as ever, but 'neutralized' by the piece of sheet iron.

"To go further: Before any form of energy can be transmitted from one point to the other it *must* pass through a conducting medium. Take the medium away and the energy cannot be transmitted any longer. To illustrate:

"Take sound, for example—a simple form of energy. A bell rings. The sound waves generated from the bell's gong travel through the air till they strike your ear drum. You hear the bell. In this case the air is the conveying medium. Take the air away and you can no longer hear the bell. Thus when a bell is placed under a glass globe you can still hear the bell. With an air pump now extract the air from the globe; you can still see the clapper of the bell strike the gong furiously, but you cannot hear a single sound, because you have taken away the conducting medium, the air.

"To go a step further: You look at the sun, some 93,000,000 miles distant from you. You see its rays, you feel its heat. Thus the sun sends a colossal amount of energy down to earth as well as to the other

Don't Wear A Truss!

After Thirty Years' Experience I Have Produced an Appliance for Men, Women or Children That Cures Rupture.

I Send It On Trial.

If you have tried most everything else, come to me. Where others fail is where I have my greatest success. Send attached coupon today and I will send you free

The above is C. E. Brooks, inventor of the Appliance who cured himself and who is now giving others the benefit of his experience. If ruptured, write him today, at Marshall, Mich.

my illustrated book on Rupture and its cure, showing my Appliance and giving you prices and names of many people who have tried it and were cured. It gives instant relief when all others fail. Remember, I use no salves, no harness, no lies.

I send on trial to prove what I say is true. You are the judge and once having seen my illustrated book and read it you will be as enthusiastic as my hundreds of patients whose letters you can also read. Fill out free coupon below and mail today. It's well worth your time whether you try my Appliance or not.

FREE INFORMATION COUPON

Mr. C. E. Brooks,
1762 State St., Marshall, Mich.

Please send me by mail, in plain wrapper, your illustrated book and full information about your Appliance for the cure of rupture.

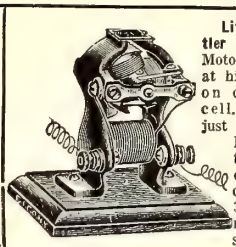
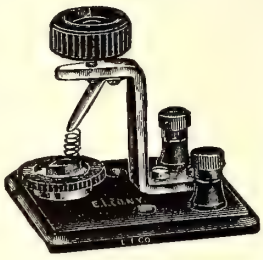
FREE! for New Subscriptions.



HERE is your chance to get valuable electrical and wireless articles free of all cost to you, by simply showing **THE ELECTRICAL EXPERIMENTER** to your friends. Most anybody will give half a dollar for 12 issues of a bright, newsy, up-to-date electrical paper like this one. When you get the number of subscriptions necessary for the premium desired, send us the total remittance with the names and addresses of the new subscribers, (or renewals), and state issue to start them with. **Every article of standard quality and guaranteed to give satisfaction.**

Midget Flashlight. Smallest made. Measures only 2½x 1¼x11/16". Beautifully finished in nickel. Fitted with high grade 2½ volt Tungsten lamp. Fits vest pocket. No. 3418 Flashlight sells for 75c. Shipping weight 4 oz.

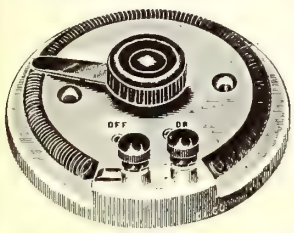
Given free for 3 yearly subscriptions.



No. 3418

Little Hustler Battery Motor. Runs at high speed on one dry cell. Built just like the large motors of commercial type. 3 pole armature; starts in any position. Stands 3½" high, perfectly finished. No. 100 Motor sells for 85c. Shipping weight 1 lb.

No. 100

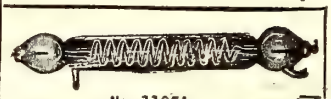


Given free for 4 yearly subscriptions or 2 two-year subscriptions.

Galena Detector, with Rotary Cup, rubber base. This detector will enable you to hear radio signals over long distances, with a small aerial. No. 9700 Detector costs $1.25. Shipping weight 1 lb.

No. 9700

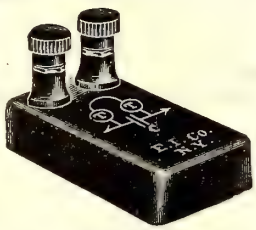
Given free for 4 yearly subscriptions or 2 two-year subscriptions.



Rheostat Regulator. Resistance 10 ohms, finely adjustable. **Porcelain base,** air cooled. Capacity about 40 watts, 2 amperes rating. Fine for controlling speed of battery motors, electro-cautery work, dimming battery lamps, etc. No. 5000 rheostat costs 60c. Shipping weight 1 lb.

No. 5000

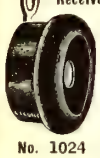
Given free for 2 yearly subscriptions or 1 two-year subscription.



SEE NOTE BELOW HOW TO CALCULATE FOR MORE THAN ONE SUBSCRIPTION.

Geissler Tube, 3 inches long. Most beautiful tube you ever used on your spark coil. Several colors show. A ¼" or ½" spark coil lights tube nicely. Gives a very weird effect. No. 1125A Geissler tube sells for 30c. Shipping weight 1 lb.

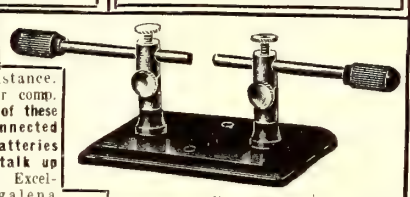
No. 1125A



Given free for 1 yearly subscription.

Jr. Fixed Condenser. Hard rubber comp. case. Widely used in radio receiving circuits. Should be used with tuner, phone and detector here shown, etc. Cap. .0165 M. F. size 2⅝x1½ x1¼". No. 10010 condenser sells at 50c. Shipping weight 4 oz.

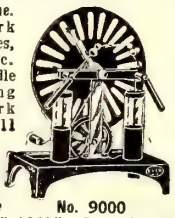
No. 10010



Given free for 2 yearly subscriptions or 1 two-year subscription.

Pony Telephone Receiver. Single pole, 75 ohms resistance. Hard rubber comp. shell. **Two of these receivers connected without batteries will carry talk up to 150 feet.** Excellent with galena detector for wireless. No. 1024 receiver, regular price 40c. Shipping weight 1 lb.

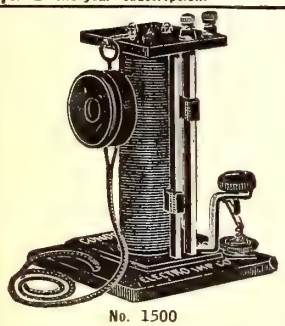
No. 1024



Given free for 2 yearly subscriptions or 1 two-year subscription.

Zinc Spark Gap, works on any spark coil. Can be used as an anchor gap or break gap in "break-key" systems. Zinc rods are 3/16" in diameter, and fitted with two insulated handles. Handsome instrument. Base is hard rubber comp. No. 9220 spark gap sells for 60c. Shipping weight 1 lb.

No. 9220

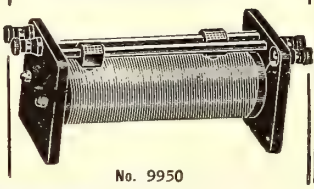


Given free for 2 yearly subscriptions or 1 two-year subscription.

Static Machine. Gives 3" spark without batteries, dynamos, etc. Simply turn handle and crackling blue-white spark leaps the ball gap. Two 7" Electrite plates. Lots of experiments available. Best machine made. Size 8x5x10½". Price $3.75. Shipping weight 6 lbs.

No. 9000

Given free for 12 yearly subscriptions or 6 two-year subscriptions.



"Interstate" Wireless Receiving Set. Receives messages up to 300 miles on fair size aerial. Has tuning coil, detector, condenser and 75 ohm receiver. Hard rubber comp. base and top. No. 1500 Interstate set sells for $3.75. Shipping weight 4 lbs.

No. 1500

Given free for 12 yearly subscriptions or 6 two-year subscriptions.

Jr. Tuning Coil. A beautiful instrument. Bare wire wound. Polished hard rubber composition ends. Two sliders. A useful loading coil, 400 meters wave length capacity. No. 9950 tuner sells at $2.00. Shipping weight 2 lbs.

Given free for 6 yearly subscriptions or 3 two-year subscriptions.

No. 9950

1000 Ohm Wireless Receiver. Very sensitive. Single pole. Moulded shell. Steel magnet powerfully magnetized. Coil wound with enameled copper magnet wire. Well made throughout. No. 1024A 1000 ohm receiver sells at $1.00. Shipping weight 1 lb.

No. 1024A

Given free for 4 yearly subscriptions or 2 two-year subscriptions.

NOTE—Your own subscription may be included in the above offers. If you are a subscriber already we will extend your subscription. Example: Suppose you desire the No. 9700 Galena Detector: you may get four friends, each to subscribe for 1 year; or three friends and yourself for 1 year; or two friends for 2 years; or two friends for 1 year and yourself for 2 years; or finally yourself for 4 years, etc., etc., whichever way you like.

Collect the $2.00 for us and the Detector is yours.

The Electrical Experimenter

Premium Dept. 233 Fulton Street New York City

planets. What is the necessary conducting medium here? The luminiferous ether, that mysterious fluid, so fine, so intangible that man has as yet never seen, nor felt, nor weighed it. Nevertheless, we have long known of its existence. It fills the pores of the densest metal as well as all space in the universe. There is no atom on earth or in the heavens which it does not permeate completely at all times.

"But of course this is all well known to you. I simply recite it so that the following may become plain to you:

"I take a glass tube five feet long, in which I place a piece of cork. Then I exhaust all the air from the tube. When I turn the tube upside down the cork will, of course, fall from the top of the tube to the bottom. Through what medium does the energy of gravity pass to reach the cork and force it to fall down? The ether. I now take my gravity insulator, place it between the tube and the earth and turn the tube upside down. What happens? The cork no longer falls down, but stays on top; furthermore, the entire tube, cork and all, 'floats' in the air when my hand releases it. Gravitational force cannot reach the tube. It is 'insulated,' the same as glass insulates electricity and prevents it from leaving its conducting wire.

"My gravity insulator is simply a curiously arranged wire netting of insulated *Marconium* wires crossing each other at right angles. Marconium is a certain metal of the rubidium group discovered by me; a netting of this wire, when excited with a powerful current of a peculiar wave and a frequency running into the millions, acts as a perfect insulator toward gravity BECAUSE IT NEUTRALIZES THE ETHER ABOVE AND BELOW IT. When placed above the ground you can pile tons of metal or stone or any other material over it. It will not touch the gravity insulator unless you push it down on it by applying an external force to it. The material cannot drop on the insulator by its own weight because NOTHING HAS WEIGHT IN SPACE, WHERE THERE IS NO GRAVITY.

"To prove this axiom I placed a spring scale over my gravity insulator. The scale stayed, of course, suspended as soon as I took my hands away from it. Now I placed weights on top of the scale, starting with a one-pound weight. The scale registered no weight, even when I increased the weight to 100 pounds. Under normal conditions my weights would have tipped the scales to 100 pounds. On top of the 'insulator' the 'weight' had vanished, the same as the sound of your bell will vanish, when you place it in a vacuum. In order that you will not draw any wrong conclusions, let me state explicitly that the *etherless zone is confined only to about one inch above and below the Marconium wire netting.* Thus any object placed above the 'insulator' is, of course, surrounded by ether *else you could not see it.* But gravity on earth (unlike ether) acts only in a straight line, this line passing through the center of the earth.

"For this reason objects placed above my 'insulator' will only stay suspended if placed directly above it. If a part of the object extends over the edge of the netting the object will fall down on the netting, because gravity will pull down on the 'exposed' part of the object. In order to carry out these experiments successfully it is quite necessary that the sun, as well as the moon, are quite below the earth's horizon. If this precaution is not taken the object above the 'insulator' will be attracted immediately toward the sun or toward the moon unless another gravity insulator is placed *above* the object to neutralize the sun's or the moon's gravitational attraction.

BUILD YOUR OWN
GRANDFATHER'S CLOCK
WITH OUR HELP

We furnish blue prints, finishing material and instructions. Buy the works, dial, weights and pendulum from us at surprisingly low prices. You make a fine profit building artistic clocks for your friends. Complete works, $5.00. Others with chimes at all prices. Ask for attractive free offer.

Clock Company
1661 Ruffner St.

September Morn
WATCH FOB. Exactly like illustration. The latest fob out. Has bewitching little figure of Miss "September Morn" handsomely embossed on heavy metal plate. Beautiful oxidized silver finish. Size of medal 1½ x 1¾. Genuine black leather strap. Boys, a real work of art. Classy, alluring. **Makes 'em all take notice.** Agents wanted everywhere. Dandy sample fob and our great easy money proposition to hustlers sent **Postpaid 25 cents.**
NOVEL JEWELRY CO.
707 Lewis Block Buffalo, N. Y.

"My invention completed, I immediately set to work toward building a machine which would enable me to leave the earth. I accordingly constructed a very strong steel globe about 60 feet in diameter, which was to take me out into space, my first planned excursion having for its object our nearest neighbor in space, the moon, only 240,000 miles distant.

"The steel globe which was to take me to the moon has its entire outer surface covered with a double Marconium netting, the free, insulated wire ends of the netting entering the globe, where they are connected to an elaborate switching arrangement.

"Running around the globe's circumference—its 'equator'—a wide belt or track is provided. This is the 'landing' track; on it the globe can readily roll over the ground without damaging the Marconium wires underneath. This track is also made of Marconium and is carefully insulated from the rest of the globe. The interior of the globe is well furnished for all comforts and has a powerful electric plant, similar in many respects to a modern submarine power plant.

"After having completed all arrangements, having stocked the machine with all kinds of provisions, fuel and many scientific instruments and apparatus, I made ready to leave old Mother Earth. The trip proving to be extra hazardous, I took only one person along, an intimate friend of mine, Professor Hezekiah Flitternix, of Columbia University.

"The only other animate passengers of the expedition were Buster, my fox terrier, and Pee-Pix, the Professor's canary bird, which he refused to leave behind.

"The moon being full and almost overhead, we entered my machine, which I had christened the evening before as *'The Interstellar.'* The heavy, soft, rubber-lined steel doors having been screwed up airtight, in order that our air should not be drawn out once we were in the open space, I started the generating apparatus. I switched on the Marconium wires which covered the outer surface of the *'Interstellar,' but only that section which was turned toward the earth.* The other half of the netting turned toward the moon was not switched on.

"Through the glass portholes at the bottom of the machine we could see the Marconium wires glowing in their characteristic green glow. Immediately we were lifted toward the moon overhead at a frightful speed. In less than 90 seconds the entire American continent became visible, and in a few more seconds the earth in its true form as an immense globe stood out against a pitch-black sky.

"As light cannot pass through an excited Marconium netting, it was necessary to switch off the current for a few seconds, every time we wished to see earth beneath us.

"The upper part of our machine (turned toward the moon) was now subjected to the moon's gravitational attraction—the earth, on account of the machine's other half being gravity-insulated, no longer attracting it. We were, therefore, 'falling' toward the moon at a constantly increasing speed and—"

At this juncture I heard Münchhausen curse roundly and his voice became indistinct. I barely made out the words: "Power low—tomorrow, 11 P. M.——" then the peculiar screaming sound in my phones, running down the scale; the low click, then everything quiet. . . . . .

The next story is entitled
"Münchhausen on the Moon."

Your Hands Can't Earn the Money You Need

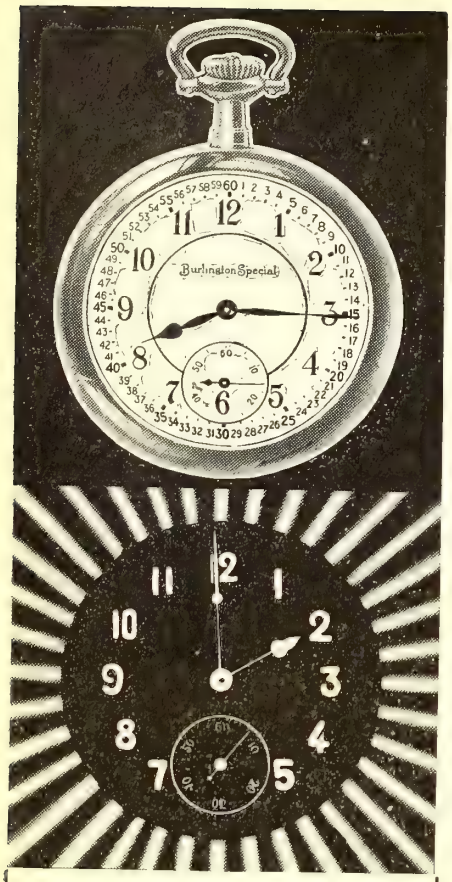
You'll have to work for low wages all your life if you depend upon your hands to make your living. To earn more money you've got to learn how to work with your *head*—you must have *special training* for some particular line of work.

And you can get this training without leaving your home or losing an hour from your work—the International Correspondence Schools can bring it to you right in your *own home* during your *spare time.* They can train you for the very job you want—where you can earn more than enough money to meet your needs.

If you want to advance in your present occupation, the I. C. S. can train you for promotion. If your present work is not pleasant, the I. C. S. can qualify you for a good position in the kind of work you like best.

Every month more than 400 I. C. S. students of all ages and occupations voluntarily report getting better jobs and bigger pay as a direct result of I. C. S. training. What these men did *you* can do.

Mark the Coupon—Now



What occupation attracts you most or what position do you want? Mark it and mail the coupon now, and learn how the I. C. S. can help YOU to earn more money.

New Ideas in Watches

Tell Time At Night!

Send for watch catalog describing, among others, the new radium dials that shine at night—*the remarkable discovery that enables you to read time plainly in pitch darkness!*—Also other new ideas:

Ribbon designs
Enamel monograms
Rich gold and color effects—

your initials in colors on a rich gold background. The new catalog shows many other novel ideas in Burlington Watches.

On Approval: The New radium dial Burlington or any other Burlington, with your own monogram engraved on the suberb gold strata case, will be sent to you *on approval*, prepaid, without a cent in advance. You risk absolutely nothing—you pay nothing—not one cent, unless you want *this exceptional* offer after seeing and thoroughly inspecting the watch.

If—after examination—you decide to keep it, pay only the **direct** rock-bottom price—the same price that **even the wholesale** jeweler must pay. And in order to encourage everybody to secure this watch now we allow this rock-bottom price, either for cash or $2.50 a month. Remember—we send this watch on approval.

Send the Coupon for New Watch Book

Learn the inside facts about watch prices and the many superior points of the Burlington over double-priced products. Just send the coupon or letter or postal. Don't delay—write today—get this offer while it lasts.

POLYTECHNIC ELECTRICAL ENGINEERING SOCIETY.

The Electrical Engineering Society of the Polytechnic Institute of Brooklyn held its annual affair on April 23 at the institute building. Dr. Clayton H. Sharp, of the Electrical Testing Laboratories of New York, gave an interesting lecture on "The Effects of Color and the Modern Development of Electric Illumination."

Illumination by electricity was first introduced by Thomas A. Edison in 1880. His lamp filament was made from charred bamboo strips, known to the trade as carbon filament. The glowing filament produced a yellow light. The efficiency of this lamp was about seven watts per candle. The efficiency of the original Edison filament has been increased to four watts per candle. From 1880 to the present time a variety of filaments have appeared in the illumination field, such as squirted cellulose, 3.1 watts per candle; metallized carbon, 2.5 watts per candle; tantalum, 2 watts per candle; squirted tungsten, 1.25 to 1.5 watts per candle; drawn tungsten, 1 watt per candle, and drawn tungsten in a nitrogen-filled atmosphere, consuming .5 to .8 watts per candle. Dr. Sharp then showed five booths, each containing the colors of the spectrum in cloth fixed in a slanting position from the top and a piece of brown plaid cloth in back of the booths. The first booth was illuminated by a four-watt-per-candle Edison carbon filament lamp and the last booth was illuminated by a .5 to .8 watt drawn tungsten filament in a nitrogen-filled atmosphere. The blue cloth varied in color from a pale blue in the first booth to a dark blue in the last booth, while the plaid changed from a bright red in the first booth to a dark brown in the last booth.

After Dr. Sharp's interesting lecture everybody adjourned to the gymnasium for the dancing.

RADIO CLUB OF AMERICA MEETING.

The Radio Club of America, one of the latest and rapidly growing wireless societies, held its May meeting at Columbia University on the first of the month.

The evening was taken up with the reading and discussion of two excellent papers by Mr. Paul F. Godley. The titles of the papers were "The Measurement of Intensity of Received Radio Signals" and "Radio Activities on the Pacific Coast."

Mr. L. G. Pacent presided as chairman, and Mr. P. Johnston, secretary of the club, also had a few words to say. The discussion was opened by Mr. Harry Sadenwater, radio inspector for the port of New York, and several other members present contributed to the discussion. Among prominent members present were: Mr. Fritz Lowenstein, consulting radio engine r; Mr. Alfred P. Morgan and Mr. Walter Lemon.

A complete audion receiving set with several bulbs for producing beats was demonstrated and signals from San Francisco were heard plainly. Stations up to 800 miles and more away were heard by means of the audion amplifier and horn all over the lecture room.

The General Electric Co. is building a high frequency wireless alternator to yield 50-75 kilowatts at 50,000 cycles. These are to be compared with the 75-100 K. W. Poulsen arcs now in use for long-distance radio work.

Avoid touching radio detector crystals with the fingers, as oil from the skin adheres to the crystal, thereby reducing its sensitiveness.

WE buy, sell and exchange. Bargains in Microscopes, Telescopes, Binoculars, Cameras, etc. Bargain list sent. Kahn & Son, Opticians, No. 54 John St., New York. Established 62 years.

SPOT Cash paid for high-grade Kodaks, Lenses and Cameras. Send full description, stating lowest price. Cameras exchanged. In business since 1885. David Stern Co., Dept. M, 1047 W. Madison St., Chicago.

FILMS developed, 10c., all sizes. Prints 2¼x3¼, 3c.; 2½x4¼, 3½x3½, 3¼x4¼, 4c.; Post Cards, 50c doz. Work guaranteed and returned 24 hours after receiving. Postpaid. Send negatives for samples. Girard's Commercial Photo Shop, Holyoke, Mass.

ROLL Films developed 10c. per roll. Printing Post Cards, 3c. each. 15 years' experience. Give me a trial. You will be pleased. F. C. Hoyt, Sac City, Ia.

EXPERT Kodak Finishing! Send for price list. Electric Studio, 162 Stephenson St., Freeport, Ill.

KODAK films developed. 5c., all sizes. Prints, 3c. each, any size. P. Johnson, 100 W. Bridge St., Oswego, N. Y.

TRANSFER pictures to china, etc.; no formulas; particulars. Flinn, 286 West 142nd St., New York City.

THINK OF IT! Only $20 for finest German Double Anastigmat in Ibso shutter, for 3A Kodaks and postal card cameras. Send for matter describing best Lenses on earth at way down prices. Lafbury Co., 305 North Fifth Ave., Chicago.

FILMS developed 10c., all sizes, prints 2¼x3¼, 3c.; 2½x4¼, 3½x3½, 3¼x4¼, 4c.; Post Cards, 50c. dozen. Work guaranteed and returned 24 hours after receiving. Postpaid. Send negatives for samples. Girard's Commercial Photo Shop, Holyoke, Mass.

$54 CENTURY Grand, bargain, $25. Magnificent Ensign Reflex, Zeiss Triotar Anastigmat, complete, $65. $22.50 Autographic Kodaks, $19.75. Slipin Calender Mounts, assortment, $1. Catalognes mailed. Newark Photo Supply Co., Newark, New Jersey.

HEADQUARTERS for selling or exchanging Cameras of all kinds. Carry a full line latest Kodaks. Graflex. Premos, foreign Cameras. Write for big bargain list. Gloeckner & Newby Co., 171 Broadway, New York.

KODAK Films Developed, 10c. per roll, any size. Prompt attention given mail orders. Prints, 2¼x3¼ to 3¼x4¼, 3c.; 4x5 to 3¼x5½, 4c. J. M. Manning, Box B, 1062 Third Ave., New York City.

MOVING Picture Camera. No larger than a kodak, uses standard film. Catalogue free. Goff, 3440 Michigan Ave., Chicago.

PRINTING

POSTPAID—1,000 envelope slips, 75c.; 500 two-color bond letterheads, or envelopes, $1.00. Samples free. The Ryder Print Shop, Dept. M6, Barnerville, N. Y.

PREPAID, Printing (600 miles) 1,000 bond letter heads, $2.39; envelopes, $2.14; return envelopes, $1.77; imitation typewritten letters, 150 words, $1.73; 300 words, $2.64; 6x9 circulars, $1.75; art ad slips, $1.00. Ask for prepaid prices on any printing. Good's Quick Print, Harrisonburg, Va.

MAGIC AND TRICKS

MAGIC pocket trick free. Worth 25c. With illustrated catalog of 250 tricks, puzzles, illusions, for 6c. Stamps. Magic Co., Sta. 10, 249 West 38th St., New York.

POST Cards, Tricks and Jokes, Coins, Notes, Stamps and curious things. Catalog for stamp. Coin Exchange, New Rochelle, N. Y.

BIG Catalogue. Magic, Entertainment goods free. Bates Co., Melrose, Mass.

MAGIC Tricks, Jokes and Puzzles. Trick with my catalogue, 10c. coin. H. V. Dils, Huntington, W. Va.

GREAT book wonders, secrets and mysteries and novelty catalogues, 10c. Wright Spec. Co. (D), Brewster, N. Y.

MAGIC tricks for the profession. Big catalogue and pocket trick free. Ventriloquial figures, $6.00 up. Magic Parlors, 192 Clifford, Providence, R. I.

NOVELTIES, Books, Tricks, Games, Etc. Illustrated catalogue free. Sample 25c. card trick, 10c. Auburn Supply Co., Specialty Dept., 7745 Peoria St., Chicago.

SECRO-WRITO; New System of secret writing. Keeps your correspondence safe and private. Strangers cannot read your cards and letters. Great fun for everybody. Samples and instructions, 10c. H. J. Teeple, Decatur, Indiana.

GREENBACKS—Yellowbacks, Stage money. New kind, 10c. bunch; 4—25c. Eureka Supply, P29, 3827 N. Kenneth, Chicago.

250 MAGIC Tricks with cards, coins, etc., 10c. Greenbacks, big wad, 10c. Novelty Shop, 3311-T, Belleplaine Ave., Chicago.

GIVE 'em the "creeps" with the Mysterious Skull. Shines, without any light, in the dark. Really wonderful, 10c. Bartlett, Box 960, Milwaukee.

MODELS

MODELS made for inventors; general machine work; designing and perfecting; developing automatic devices and machinery; in a position to do all kinds of light tool and machine work. Prices reasonable; estimates cheerfully given. Ideal Machine Works, 62 Ann Street, New York City.

INVENTORS: We manufacture metal articles of all kinds to order. Also special machinery, tools and dies; punchings, lathe and screw machine work, metal spinnings, castings, plating, wood and metal patterns, etc. Send sample for estimate and expert advice, free. The Eagle Mfg. Co., Dept. B, Cincinnati, Ohio.

SMALL Gasoline and Steam Engines and Castings. Experimental apparatus. Toys. Big catalogue for 10c. Amateur Mechanics Co., First National Bank Building Chicago.

PRODUCERS of Results; Inventions Developed, Light Mfg., Models, Experimental Work, Tools, Dies and Stampings. Johns Machine & Stamping Works, Middle Bldg., Dept. C, Cleveland, Ohio.

MODELS, dies and manufacturing for inventors, by builders of "Tools That Work." La Croix Tool Co., 214 N. 21st St., St. Louis, Mo.

MISCELLANEOUS

ENGINE Lathe, swings 9½ in., takes 25 in. between centers. Complete set gears cutting all size threads 3 in. to 40 in., $43.50. Grammes & Sons, Allentown, Pa.

MANSFIELD'S Electrical Water Finder is a thoroughly reliable appliance for locating positions for sinking wells for pure water supplies. Send for particulars to Mansfield & Co., Engineers, New Brighton, England.

THE FRITZ NOVEL INSULATOR for sale, outright or royalty. Osville J. Fritz, Weisenburg, Pa.

WATCH and Phonograph for sale cheap. Box 424, Waubay, S. Dak.

PATENTS without advance attorney's fees. Not due until patent allowed. Send sketch for free report. Books free. Frank Fuller, Washington, D. C.

STAMPS AND COINS

STAMP Album with 538 Genuine Stamps, incl. Rhodesia, Congo (tiger), China (dragon), Tasmania (landscape), Jamaica (waterfalls), etc., 10c. 100 diff. Jap., N. Zld. etc., 5c. Big list; coupons, etc. Free. We buy stamps. Hussman Stamp Co., St. Louis, Mo.

GET the most out of your money you can. Try my 1, 2 and 3-cent approvals and you'll be pleased. References required. Wm. Haase, 971 E. 39th St., Los Angeles, Cal.

STAMPS, 100, ALL DIFFERENT, FREE—Postage 2c. Mention paper. Quaker Stamp Co., Toledo, Ohio.

FOREIGN Stamps Free, 52 different foreign, including China and Venezuela, to all who apply for our high grade approval selections. Send two cent stamp for return postage. Edgewood Stamp Co., Dept. H, Milford, Conn.

$4.25 EACH paid for U. S. Flying Eagle Cents dated 1856. Hundreds of other U. S. and Foreign Coins wanted. Send 10c. at once for New Illustrated Coin Value Book 4x7. It may mean your good fortune. Clarke Coin Co., Box 94, Le Roy, N. Y.

MAIL ORDER OPPORTUNITIES

EVERYTHING in the mail order line; state your wants and we will do the rest. Pacific Specialties Co., Los Angeles, Cal.

EUROPEAN War Map and chances to start a profitable business of your own, 10c. C. S. Mathews, 69 East 87th St., Portland, Ore.

WE will start you in the cleaning and dyeing business. Little capital needed. Big profits. Write for booklet. Ben Vonde System, Dept. A-K, Charlotte, N. C.

MAIL Order Men. Would you like to know how 61 successful mail order men do business? Especially if these men tell you their own experience in their own words. The Mail Order Business Builder gives you such information direct from these men's private offices from month to month. Send dime for sample copy of this 64-page magazine. Randolph Rose, Publisher, No. 8 Broad St., Chattanooga, Tenn.

WIRELESS

FREE—A beautiful Wireless Receiving Set enabling you to receive messages 300 miles, for selling only 25 boxes of my Spot Remover. Sells on sight. Be one of the first in your town to own a Wireless Set. Write now. Marge Co., 702 N. 6th St., East St. Louis, Ill. Dept. K.

$10.00 COMMERCIAL KEYS for $4.00. Massie Wireless Telegraph Co., Providence, R. I.

"WIRELESS CHART" giving capacity, wave length, inductance, etc., values directly. Why wade through complicated formulas? "Chart," prepaid, 20 cents. Send stamp for list of labor saving charts. H. Secor, Consulting Engineer, 2040 7th Ave., New York City.

INCREASE your radiating efficiency. Use an Oscillation Transformer. Price $6.50. F. C. Thiede, 486 Decatur St., Brooklyn, N. Y.

DOUBLE Slide Tuners, $1.75. Extra sensitive Detectors, $1.00. Head Receivers, 1,000 Ohm Phones, aluminum Headband, $5.50 complete. Write for prices on all your wireless needs. Wm. Paul, 134 Dewey Ave., Jamaica, L. I.

BEFORE you try to wind secondaries for a coil or transformer get our prices, we can save you trouble and money. State your wants plainly. Eureka Secondary Co., 6939 S. May St., Chicago, Ill.

Scientific Exchange Columns

UNDOUBTEDLY you have at the present time some things for which you have no further use. Do you wish to sell these things or exchange them for something, for which you have immediate use? There is no surer and quicker way to do this than by advertising your articles in these columns. The **Very** people, the **Only** people, who could possibly have a use for your things read this journal. More than 30,000 interested people will see your ad. It is furthermore the cheapest advertising medium for you in the country.

The rates are: One cent per word (name and address to be counted) minimum space 3 lines. Count about 7 words to the line. **Remittance must accompany all orders.**

We reserve to ourselves the right to refuse any advertisement which we consider misleading or objectionable. Advertisements for the July issue should reach us not later than June 10th.

The Classified Columns of "The Electrical Experimenter" Bring Positive Results.

WILL EXCHANGE a 6 volt 80 ampere Willard Storage Battery for 8 volt 10 ampere dynamo, or other dynamo of similiar capacity, or phonograph of good make, or what have you. Samuel Cohen, 1936 Pitkin Ave., Brooklyn, N. Y.

STORAGE BATTERY—6/60. Sheldon School text books Powell Adv. Course. Want Electric Enlarging Lantern or good Camera. Baker, 3440 Michigan Ave., Chicago.

EXCHANGE—8x10 View Camera and large finishing outfit, fine condition, like new, cost $70.00; also one single shotgun. Want motorcycle, sporting goods, electrical goods, smaller camera or what have you. Also have a Waltham 15 jewel watch, 20 year case. Anton Rank, Buffalo Center, Iowa.

FOR SALE—New Murdock small variable for $2.00; Miller loose coupler a bargain for $1.75; or will exchange both for Murdock antenna series condenser. Write for picture. G. W. Spaulding, Osakis, Minn.

WILL EXCHANGE for motorcycle, complete wireless sending and receiving outfit, ½ K.W. transformer, Standard motor, rotary spark gap, large helix, glass plate condenser, 2,000 ohm. phones, loose coupler, loading coil, combination detector and condenser. W. R. Miller, 357 45th St., Pittsburgh, Pa.

TYPEWRITER BARGAIN—$6.00 for genuine Chicago machine, 90 characters, steel letters. These machines now being sold by the manufacturers for $35.00. This machine is practically new. Perfect condition guaranteed. Money back if not satisfactory. Also very fine triple magnet A. C. generator, $2.00, perfect condition; the magnets alone are worth the price. Hulet Mfg. Co., W. Point Pleasant, N. J.

EXCHANGE a spark gap motor A. C. or D. C. 1,500 ohm pair phones, value $12.00; want Belgian hares or watch dog. H. C. Boyer, McKees Rocks, Pa.

3,000 OHM Government phones, E. I. Co., Loose Coupler and Sending Helix, all for $5.00. Harold B. Adams, 3100 Broadway, New York City.

WILL EXCHANGE—Professional Loose Coupler, Variable Condenser, and Potentiometer (all Electro make), for Audion or Typewriter. Alfred Theis, 512 East 88th St., New York City.

HAVE Battery Motor that I will sell for 50c. Also a North Pole Alarm Clock, absolutely new, for 75c. Postage extra. H. C. Gerlach, 419 W. 119th St., New York.

WILL EXCHANGE complete I. C. S. electrical engineering library or good disc talking machine or both for small gasoline engine. E. G. Clark, Shelby, Ohio.

WILL EXCHANGE—A $4.80 Omnigraph, good as new, and a $3.75 17-Plate Electro Variable Condenser for a good Loose Coupler. Must not be home made. Delbert Myers, Box 4, Amboy, Ind.

FOR SALE OR EXCHANGE—Two cylinder, four Cycle Engine or partly finished 9 in. Lathe Castings for Audion Set. For details address Morse Lloyd, Portsmouth, O.

FOR SALE OR EXCHANGE—Electrolytic Detector and Potentiometer, together or separately. Would like to exchange pictures of wireless stations with amateurs. Donald Rockwell, Wellsboro, Pa.

TO EXCHANGE—Tandem Bicycle without tires, good coaster brake. What have you electrical? Dynamo, generator or electric fan. Charles Train, 11 Hanson Ave., Somerville, Mass.

FOR SALE—Electro Static Machine. Perfect condition, like a new machine. Postal order for $2.25 takes it. E. P. Chamberlain, Brownfield, Me.

TO EXCHANGE—Peroxide of lead Detector, Potentiometer, 1½ pint Leyden Jar, Splitdorf Spark Coil, Sounder, Battery Motor, single slide Tuner, 12 gauge Shot Gun. Carlton S. Fernyak, Mansfield, O.

WILL SELL—Two in. E. I. Co. Spark Coil, Loose Coupler, tunes 3,000 meters; Mandelett Camera; these articles are all nearly new. Burns Hempstead, Croton, O.

FOR SALE OR TRADE—One E. I. Co. "Interstate" Receiving Outfit, $3.00. Ideal for beginners, in excellent condition, will trade for Variable Condenser, Spark Coil or offers. Gartz Windenburgh, Lamont, Ia.

WILL EXCHANGE—500 shares Los Angeles Building Company for complete Sending Outfit, High Power. Joe Sykes, Los Angeles, Cal.

BARGAIN—One set Applied Electricity, one set Engineering, one set Auto Engineering. Perfect condition. Also step-down Transformer, pair Duplex Phones, Detector on genuine rubber base, Water Motor. Generator 20 V. 5 Amp. Details for stamp. J. A. Wever, 233 S. Patterson Park Ave., Baltimore, Md.

FOR SALE—Five-Ohm Telegraph Instrument, $1.00; double leather covered Headband, 80c.; Omnigraph No. 3777, $1.50; "Electro" Loading Coil, $2.20; Loose Coupler Receiving Outfit, $4.25; Hand Printing Press, lots of type, $4.00. All in good condition. Owen Cook, Marinette, Wis.

WILL SELL—Twelve-inch High Frequency Coil, direct or alternating current; six-inch X-Ray Tube for same; 5x5 Fluorescent Screen. All as new. Reasonable. Irvine, Box 325, Bay Shore, N. Y.

HAVE Violin, Camera and Outfit, Telescope, 1,000-ohm Single Headset, ¼-inch Spark Coil, Loading Coil and lot of other chemical, wireless and electrical apparatus, also large variety of books. Send for complete list. Will sell cheap or exchange for double headset, loose coupler, spark coil or what have you? O. Vandt, 118 Crane St., Schenectady, N. Y.

FOR EXCHANGE—Phonograph (Cabinet) and nine Double Records; cost $25.00; Rifle, cost $7.50, for wireless goods and static machine and apparatus or offers. Bernard Merrick, Conneaut, O.

WOULD like to buy an Omnigraph in good condition. Please write Joseph Klauser, 388½ Pulaski St., Brooklyn, N. Y.

SHEET Fibre, ½ in. thick, $1.50 sq. ft.; ¾ in., $2.25 sq. ft.; 1 in. thick, $3.00 foot. Will sell ½ sq. ft. or over. George Blum, 817 West End Ave., New York.

WILL SELL cheap. Bunnell battery rheostat, 40c., also small rubber switchboard, $3.00; no instruments. Jos. Lowenstein, 255 W. 112th St., New York.

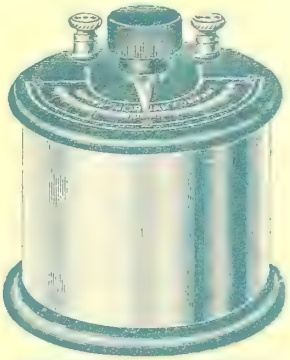
STOP!

We hereby present one of the greatest bargains in electrical literature ever offered.

A complete Volume of the *Electrical Experimenter*, bound in rich, dark green linen, stamped with gold letters at the extraordinary low price of

75c.

Volume contains twelve numbers (from May, 1914, to April, 1915), **240** pages, **350** complete articles, **550** illustrations, **396** questions and answers.



A world of electrical information; the entire electrical Progress for one year; the greatest reference book on current "Wireless"—all at a price as low as the *unbound* copies would bring. Mind you, the book is durably bound with heavy covers. You will be proud to have it in your library. We have only a few hundred copies, therefore be sure and order today. Shipping weight 2 lbs. Add a sufficient amount for postage.

"The Obsolete Submarine"

IN analyzing past and present means of warfare, we invariably find that it is possible to combat weapon by weapon. Thus the early cliff dweller could combat his club-swinging adversary by means of a club; the one swinging the club most adroitly won. You can combat the lance with a lance; a sword with a sword; gun against gun; one cannon can fight another with a cannon; one battleship can attack and combat successfully another battleship. But—and here we have a singular exception, the paradox of the present war—you cannot fight one submarine with another submarine. Nay, you cannot properly combat—as that term is understood—the submarine with any present means. For we cannot fight what we cannot see; to-day, as in the past, the most dangerous enemy is the unseen one.

The modern submarine is dangerous only because of its invisibility. If we find a means to make it "visible" the submarine will become obsolete. When this moment arrives the battleship will come into its own again, as well it may.

The present submersible is made possible only due to the use of electricity; it could not exist without that agency. Our imagination need not be stretched unduly to presume that electricity will, in the not too distant future, be employed to render the submarine harmless. Indeed, scores of our greatest scientists all over the world are working along these lines, our own FESSENDEN having already obtained certain results which seem exceedingly promising.

Speaking generally, a ship is safe in a harbor; it is endangered only in the open sea. If the captain has accurate knowledge of the whereabouts of the submarine and if he runs away from it at full speed his ship, as a rule, cannot be overhauled by the relatively slow undersea craft. The obvious problem then is to locate the submarine when it is as yet from three to five miles distant. It is, of course, necessary also to know in what direction the submarine is located, because it may make for the ship, running submersed, without showing its periscope.

How can we locate it then? The problem does not present unsurmountable difficulties. Several means may be used. We can imagine a very refined magnetic indicating detector mounted below water on each side of the ship. If this detector is sufficiently sensitive to large iron or steel masses (it could be shielded against its own ship) it would become a simple matter of locating the submarine or even a mine. For it must not be forgotten that a submarine of necessity sends out a considerable magnetic flux.

Another means to detect submarines lies in the use of some form of etheric waves. We can imagine an apparatus, say at the bow of the ship, sending out waves below the water while a suitable detector at the stern, also below water, is used to register the "echo" and its intensity. The original waves striking the submarine will be reflected and bent back. The intensity of these reflected waves could be made to read off on a direct recording scale, giving the distance of the submarine in miles. Recent researches show the possibility of sending etheric waves below water, so we may be sure that the interesting problem of locating submarines will not remain unsolved for any great length of time.

The above presents such a rich field of opportunities for the investigator that it seems worth while to bend all our energies toward its successful solution. Humanity will breathe easier when the now treacherous submarine can be successfully combated.

DO YOU KNOW HOW TO—

Figure the number of turns of wire required for the primary of a transformer of any size?

Design and build a magnetic leakage transformer?

Build an induction coil to give a heavy, 1-inch spark with only a pound of wire in its secondary?

This Book at 25 cents will tell you how.

New Revised Third Edition.

CONSTRUCTION OF INDUCTION COILS AND TRANSFORMERS

By Thomas Stanley Curtis.

Contains information hitherto unpublished in book form, written for the amateur in plain English; practical instructions for building high-and-low-voltage, magnetic leakage, high frequency, and other special transformers; interrupters, condensers, gaps, etc. Also chapter on high frequency experiments.

Sent Prepaid on Receipt of Price.

HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books Price per $1 Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

"THAT'S JUST WHAT I NEED"

They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED

FREE EXAMINATION OFFER

Theo. Audel & Co., 72 5th Ave., New York

Please submit me for examination HAWKINS ELECTRICAL GUIDES (Price $1 each.)

Ship at once, prepaid the 6 numbers; if satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

Practical Courses of Study

ELECTRICAL ENGINEERING

The men who get the **big jobs** are the men who understand the **principles** of electricity and their application.

Our Electrical Course teaches in plain, simple language and with easy lessons how to install and operate electrical machinery and appliances.

These lessons in Practical Electricity cover both Direct and Alternating Currents, high potential and high frequency currents, and all that is necessary to become a proficient electrical engineer.

The Course completely covers the field of practical electricity, including power-plant work, and the following subjects, viz.: Practical Electricity, Alternating Currents Simplified, The Electric Motor, Electric Wiring and Practical Mathematics.

FREE Ten text-books, handsomely bound, printed in large, clear type on fine quality of paper and profusely illustrated, are furnished **free** with this course.

The instruction is made so clear that any one can understand it, even though he has but a limited education.

The success of this school is due to the fact that we give the student only what he should know in order to become competent, and we do not waste his time and effort on useless matter.

FREDERICK J. DRAKE & CO.

1325 E Michigan Ave. CHICAGO, ILL.

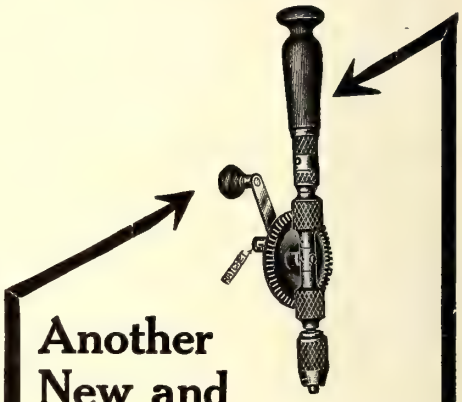
200 Kinds Iron, Wood, Wire & Steel Puzzles

Catalog and Sample, 10c. 3 Leaders for 25c.

WESTERN PUZZLE WORKS

Dept. 30 St. Paul, Minn.

FREE ADVICE



given by experts in regard to any electrical, mechanical or other technical books. So many books are published about each subject, it is difficult for most persons to know which is the best book for his particular purpose.

Electrical, Mechanical and Other Technical Books

for home study or for reference. In return for this free service we ask that after you have decided what book you want, you will order it from us. Our price will be as low as you can buy it elsewhere. Send for details of our plan and state which subject you are interested in.

Technical Service Bureau, 51 E. 42d St., New York

BOY Scout Field Glass, Telescope and Compass Combination Instrument given for selling only 10 bottles of Perfume at 10c. each and remitting $1.00. This is a special offer and is limited. Get busy now and get one. **A. E. Anderson, 51 Carlton, Grand Rapids, Mich.**

Another New and Improved Tool of Millers Falls Make

Here is a new hand drill designed to do a better job in quicker time with less effort and less trouble and fulfilling each purpose perfectly.

MILLERS FALLS

HAND DRILL No. 306

It is provided with a simple and effective ratchet, located on the crank handle, which is of great convenience when working in cramped corners or on a delicate job. The handle is detachable and hollowed for holding twist drills up to the largest size within the capacity of the chuck. The chuck is of the famous STAR three jaw pattern closing evenly on, and centering accurately, round shanks from 0 to ¼ inch in diameter. Jaw springs are protected from injury.

Solid steel frame. Cut gears with a small steel working gear and steel idler gear to equalize bearings, both encased and rendered dirt-and-dust-proof. Choice hardwood stained handle, all metal parts handsomely nickeled with exception of large gear.

The splendid quality of material and workmanship in this drill is typical of all tools of Millers Falls Make. Ask your dealer to show you Hand Drill 306 and also Millers Falls Bit Brace 732, Automatic Borer 8 and Hack Saw Gauge 53, new tools that include new features to make work easier.

Send for pocket catalog showing complete line.

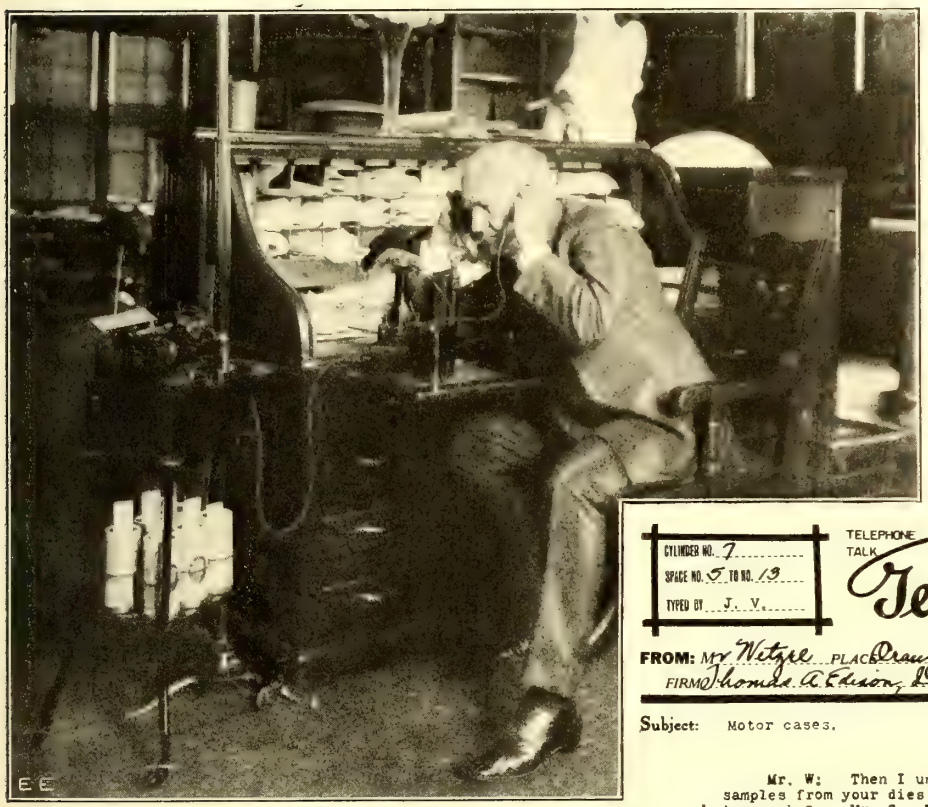
Edison Perfects the "Telescribe"

THOMAS A. EDISON, at sixty-eight, announces the perfection of the telescribe, a combination of telephone and phonograph, by which the telephonic conversation of persons 3,000 miles apart can be perfectly recorded on a wax record. Its completion gives Mr. Edison the credit for more than 1,500 inventions and more patents than ever have been issued to any other individual.

With the telescribe, "canned evidence" of a litigant's own words in his own voice may be heard by a jury.

The telescribe consists of a sensitive telephone for desk use with controlling buttons to operate a recording machine nearby. It is so sensitive and so adjusted that the slightest vibration is recorded.

When he invented the carbon telephone transmitter and the phonograph, thirty-eight years ago, Mr. Edison conceived the idea of the telescribe. More than a generation of invention and scientific development is centered in the new apparatus, which Mr. Edison says "the world will soon recognize as a great commercial asset. It makes the telephone more useful, the phonograph more valuable and both more necessary."



Had there been a telescribe at either end of the transcontinental wire between the White House and the Panama-Pacific Exposition when President Wilson spoke the words that opened the fair, his sentences might have been recorded and perpetuated for posterity.

After the words of the telephoning persons are recorded on the wax record if important enough, it may be preserved, or it may be used 100 times if the intelligence on it is taken by a typist and the record "shaved." What is known as a "telescript," a patented form somewhat similar to a telegram and here shown, is signed and mailed to one of the parties that has talked, should he desire an exact copy of the entire conversation. In case of a long distance telephone call, which involves considerable expense, in the absence of the person desired, one in the office need only to press a button and the person at the other end may speak what he has to say into the phonograph to be listened to later by the person for whom it was intended.

More than a generation of invention and development is centered in the telescribe.

The two arts—telephonic and phonographic—which it combines, have been closely associated in Edison's mind from the earliest development. His experience with diaphragm action in the carbon transmitter in 1876 led immediately to the invention of the phonograph in 1877, and we find his early prophecy of the telescribe in these words:

FIRM Thomas A. Edison, Inc. FIRM C. M. Grey M'f'g Co.

Subject: Motor cases.

Mr. W: Then I understand, Mr. Grey, if we approve the samples from your dies today, we can expect deliveries within two weeks? Mr. G: That's sure, if I can get your order for at least five thousand (5,000). Mr. W: The order for 5,000 goes tonight with the approved samples, but I've got to know we will get the first cases by April 15th, delivered 500 a week after that. Mr. G: You get me the approved samples with the order, and I'll do my part. Mr. W: Say, Grey, I want you to note the change we made in the top lugs----we've made them a little heavier. Don't forget to change your dies before you commence the run. Mr. G: That will be all right.

Approved C. J. Wetzel
Production Mgr.

A Day With William J. Hammer

By Samuel Cohen

IT was a mid-week day, not long ago, when I took advantage of the invitation extended by William J. Hammer to visit him in his laboratory in New York City.

First and foremost, Mr. Hammer is a consulting electrical engineer, and was one of Edison's earliest assistants at his Menlo

Mr. William J. Hammer the Well-Known Consulting Engineer of New York City.

Park laboratory during the development of the incandescent lamp, telephone, phonograph, electric railway, etc. This gentleman was one of the real pioneers of the incandescent electric lamp and in the development of the transmission of electrical power, both here and abroad, having been chief engineer of the English Edison Co. in 1881-2, also chief engineer of the German Edison Co., known as the Allegemeine Elektricitaets Gesellschaft, in 1883-4.

In 1883 Mr. Hammer invented and constructed the first motor-driven electric "flasher" sign, now universally employed. This sign, which flashed the name "Edison," letter by letter and as a whole, by means of a commutator or "flasher" driven by an electric motor, was placed on top of the Edison Pavilion at the International Health Exposition in Berlin, Germany; also a simpler form was constructed to be operated by hand as early as 1881, and it was used for a year at the Crystal Palace Exposition in London.

After we had had an interesting chat this great man conducted me to his marvelous laboratory, which is seen in Fig. 1. It is in this laboratory where the most wonderful experiments and discoveries imaginable in phosphorescent substances, X-rays, ultra-violet rays, radium phenomena, selenium, etc., have been conducted.

This savant is one of the leading authorities on selenium in this country and has compiled a remarkable bibliography upon the subject. Many different types of selenium cells have been devised for various purposes. Some of these he has invented and patented, and has also perfected automatic devices for starting motors, controlling gas and electric street lights, for opening iron window shutters in the morning and closing them in the evening, automatically firing cannon, the prevention of boiler explosions, protecting safes, etc. This untiring worker has also developed, to some extent, a system of "seeing over a wire" and has patented a selenium photometer. All these devices are operated with selenium cells. Various experiments have been carried on in radio-telephony by the use of selenium cells, and wireless has been employed for domestic purposes in his house, for calling servants, ringing bells, etc. He was for a time associated with the late Prof. Ernest Ruhmer, of Berlin, Germany, who is well known for his experiments in radio-telephony and selenium-cell work, as well as for numerous technical publications.

To resume: In a few minutes the laboratory became dark and the wizard performed for me several extremely interesting experiments. For instance, I was told to watch a large bouquet of artificial flowers, which appeared in their natural color. A Weintraub-Steinmetz mercury arc lamp was now lighted and kept in operation for a few moments. The lamp was then extinguished by opening a switch. The room was dark as pitch, but the flowers, roses, tulips and lilies, which could not be seen at all a minute before, now *glowed beautifully* with many different colors. Further demonstrations included numerous bottles containing chemical and mineral substances, which by exposure to the mercury lamp also radiated glowing rays, and each bottle had a different color. Figures, letters, statuettes, even model aeroplanes and balloons, etc., around the room, all became brilliant. It was explained that all these objects were coated with some special phosphorescent substances and, when stimulated by the mercury lamp rays, they will give off considerable light for a long time. The phosphorescent mixtures used on watch and clock dials and containing radium salts were originated in this laboratory. After years of study it was discovered how to combine phosphorescent and fluorescent substances so as to produce practically any brilliant color in the dark when the substances are stimulated by the mercury arc lamp or ultra-violet light, sunlight, etc. A basic patent upon this discovery has been allowed.

Mr. Hammer has spent an unbelievable amount of study on the phenomena which occur inside and outside of different types of vacuum tubes. Note the many shapes and kinds of tubes seen on the shelves of his laboratory. Another ingenious device I saw was a machine driven by electric motors, by means of which can be illustrated, mechanically, upward of 100 different forms of physical phenomena.

No less than 34 long years were expended in systematically collecting various kinds of electric lamps in this country and in Europe. This was done for the purpose of showing the complete steps in the development of the incandescent electric lamp, from the earliest work of Edison, Swan and others to the latest nitrogen-tungsten lamp. Five large glass cases, four of them 10 feet long, contain the collection, which is exhibited in the rooms of the American Institute of Electrical Engineers, 25 West Thirty-ninth street, New York City. One of these cases is shown in the photograph Fig. 2. The collection contains more than 1,000 different lamps, and this collection which Mr. Hammer has termed the "history of an art," represents the only art in the world of which such a record has been made. It is thoroughly complete and without a single important missing link.

The radiant efficiency of the original carbon-filament incandescent lamp was about .43 of 1 per cent.; that of the tungsten lamp about 5 per cent., and that of the new nitrogen-tungsten lamp is about 10 per cent. On the other hand, the light of the fire-fly and the "pyrophorus noctilucus" or, as commonly called, the *Brazilian beetle*, have an efficiency of 96.5 per cent. as shown by measurements made by Professors Langley and Very with the bolometer,

Fig. 1. The Marvelous "Hammer" Electrical Laboratory, Where Every Conceivable Interesting Scientific Instrument is to be Found.

and also by Coblentz with the thermopile. This investigator believes that "cold light" is the real light of the future. Already photographs have been taken by the light of fire-flies and other forms of "cold light" in his laboratory.

Photograph 3 shows a case of historic wires which have been collected, now all joined in one continuous circuit and containing sections of wires and cables which at various times formed parts of the most important electrical circuits in the history of electricity. At the top of the case is a piece of wire over which Prof. Samuel F. B. Morse sent the immortal first message by telegraph, *"What hath God wrought?"* Immediately below this specimen there is a length of a few inches of wire through which Prof. Alexander Graham Bell and Thomas A. Watson, his assistant, made all their early experiments on the telephone from 1875 to 1877, and through this wire passed the *first* electrical transmission of audible speech in the world in the year 1875.

The third of these historical wire mementos is a section of the Atlantic cable over which the first successful message was sent between the old and new worlds by Cyrus W. Field.

In the center of the photograph will be seen a safety fuse or plug used in London, England, on Jan. 12, 1882, to close the circuit of the first incandescent lamps ever lighted from an electric lighting central station in the history of electricity. This interesting event took place at the Holborn Viaduct Central Station, and it was Mr. Hammer himself who made the initial connection. Beneath the fuse is a portion of the first "Sprague" trolley circuit used at the historic plant at Richmond, Va., in 1888.

The sixth is perhaps the most interesting of all the relics, being a section of the deep-sea portion of the new American-Pacific cable, through which the initial "around the world" message was sent July 4, 1903, by ex-President Roosevelt. It is interesting to note that the Postal Telegraph

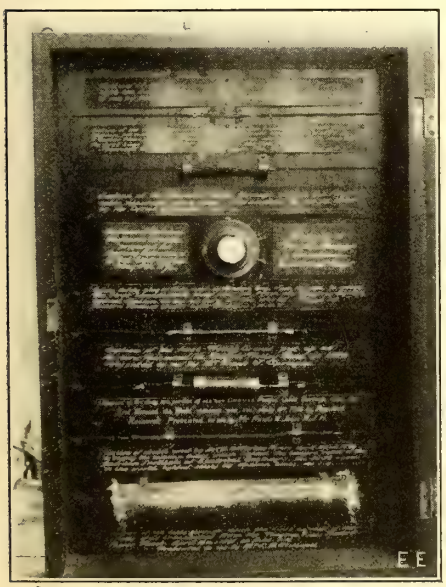

Fig. 3. Case of Historic Wires and Cables in the Wonderful W. J. Hammer Collection.

Co. borrowed this exhibit case of historic wires and connected it in the circuit. The message thus passed through all the old wire specimens. The seventh is a section of the wire through which the electricity was sent to illuminate the headquarters of the A. I. E. E. by Moore's system of vacuum tube lighting, this being the first room in the world so lighted. The eighth and last is a section of the cable through which the first electric current was transmitted from the Niagara Falls electric power plant, April 16, 1895.

Mr. Hammer is a fellow and life member

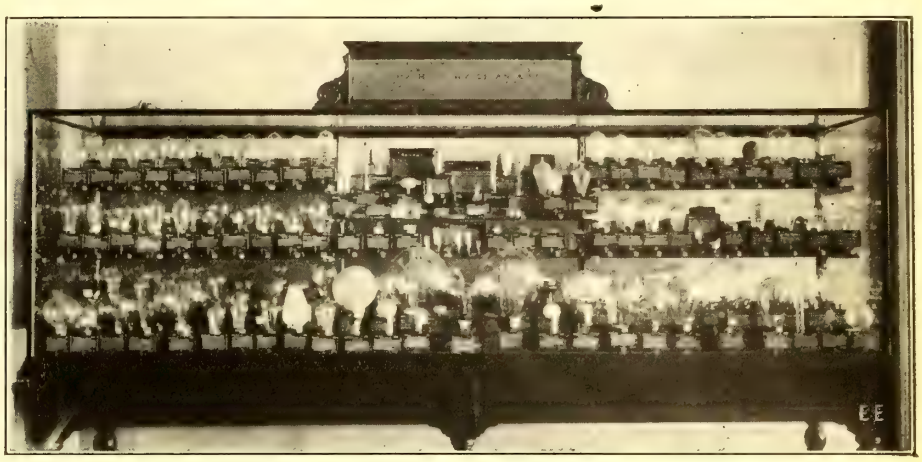

Fig. 2. Exhibit of Incandescent Lamps Prepared and Collected by Mr. Hammer. No Important Link in the Development of the Incandescent Lamp is Missing.

of the American Institute of Electrical Engineers, fellow of the American Association for the Advancement of Science and has been vice-president of the American Institute of Electrical Engineers, the New York Electrical Society and the Aeronautical Society of America and is a member of many other bodies. Also the Elliott Cresson and the John Scott medals of the Franklin Institute, the "Grand Prize" of the St. Louis Exposition of 1904, and several other medals here and abroad have been awarded this profound thinker and scholar.

Some of his numerous press contributions include a book on "Radium and Other Radio-Active Substances;" also special radium articles for the Encyclopedia Americana; editorial collaboration on the Aero Club's book, "Navigating the Air," and in conjunction with Hudson Maxim, the "Chronology of Aviation for the *World Almanac* of 1911 was compiled. This has since been reprinted and is the accepted authority upon the history of the art of flying. His multifarious duties have included that of secretary and expert of the Aeronautics Committee of the Hudson-Fulton Celebration of 1909, besides appearing for the famous Wright brothers in all their aeroplane patent suits.

Few men, perhaps, in their allotted cycle of life have been interested or identified with a greater number of engineering projects than this pleasant-faced man who counts among his innumerable personal friends the leading scientists and engineers of every country under the sun.

EDISON MEDAL GIVEN TO DR. ALEXANDER BELL.

Dr. Alexander Graham Bell, inventor of the telephone, was cheered long and heartily by a company that filled the auditorium of the Engineering Societies' Building, New York City, on May 18, where he had been summoned to the annual meeting of the American Institute of Electrical Engineers, to receive the Edison medal for meritorious achievement in electrical science.

John J. Carty, chief engineer of the American Telephone and Telegraph Company, made the presentation, after Prof. Thomas A. Watson, of Boston, mechanical expert for Bell at the time of the telephone invention in 1875, had spoken of some of the trials of the experimental period.

"The telephone has developed so much in recent years," Dr. Bell said in accepting the medal, "that I have almost forgotten my part in it. When I think of the present system I realize what other men have done, and how much we owe to them. To me Prof. Watson represents the past of the telephone, Mr. Carty represents the present and the American Institute of Electrical Engineers represents the future.

The question with me is: Are you not some day going to see by telephone? The end has not come. I am struck by the fact that nearly all recent developments has had to do with vibration. I wonder what it may not lead to, when our engineers turn their genius to some of the many other fields of the work."

EDISON PERFECTS THE TELESCRIBE.

(*Continued from page* 83.)

"Among the many uses to which the phonograph will be applied are the following: Letter writing, and all kinds of dictation without a stenographer; connection with the telephone, so as to make that invention an auxiliary in the transmission of permanent and valuable records, instead of being the recipient of momentary and fleeting communication."

Ground wires for metal mouldings must be of copper at least No. 10 B. & S. gauge.

SOME ELECTRIC LIGHTING RULES.

The following simple rules should be observed in considering lighting installations:

Don't work in a flickering light

Don't expose the eyes to unshaded lights in the direct range of vision.

Don't judge illumination by the brightness of the lamps.

Avoid extensive contrasts.

Use the right type of globe, shade or reflector.

Make sure that the illumination is sufficient.

Keep lamps, globes and reflectors clean.

Make sure that lamps are in the right position.

The Panama Canal was begun nine years ago and has cost $310,000,000; within the same space of time the Bell Telephone Company has spent twice that amount in its engineering construction work on the transcontinental telephone line alone.

New Inventions in Photoplays

NO—the photograph we see below is not that of a band of Chinese conspirators catching secret wireless messages! It depicts an interesting moment in the Pathé moving picture production, "The Exploits of Elaine," being from episode No. 21, entitled 'The Listening Ear."

The Movie Villain, "Wu Fang," and His Men Listen to "Craig Kennedy's" Conversation by Means of the Listening Ear, or, As We Know It, "The Detectaphone."

The story, of course, revolves about the leading characters of "Wu Fang" and "Craig Kennedy," the scientific detective. The Chinaman, "Wu Fang," pits his cleverness and scientific abilities against those of the well-known detective character in the story of the photo-play.

The vital moment here shown is that when "Wu Fang" manages to have his assistants install a "Detecta-phone," or as it is termed in the picture more mysteriously, "The Listening Ear," so that he and his assistants, who are located in the same building as "Craig Kennedy's" office, can overhear what he has to say to his assistant.

This picture is one of the most interesting, in several ways, of those so far shown in the famous Pathé film feature, and it is very exciting to see "Craig Kennedy" locate the hidden Detecta-phone wires in his office by means of the "Kennedy Galvanoscope." This galvanoscope is one of the largest ever seen in captivity, to put it mildly; but of course it is necessary to use large instruments which will show up in the proper way on film pictures, etc. To resume: When the instrument is brought near the hidden wires by "Craig Kennedy" the leaves of the galvanoscope, which measure about 4 inches in length, are seen to flap back and forth in a very *wonderful* manner. However, the general features of the instrument shown are undoubtedly brought out in a very strong manner, so that the uninitiated in the audience will be sure to gain the general underlying principle involved in the apparatus used.

An electrical device which has been mentioned a number of times in scientific journals in the past few years is that known as the Sphymograph, or the instrument which can record the state of human emotion. This apparatus is seen in the picture herewith presented, which is taken from the Pathé film entitled "The Exploits of Elaine" and depicts the famous characters of "Craig Kennedy," the scientific detective, portrayed by Arnold Daly, and "Elaine Dodge," in the person of Miss Pearl White.

The "Sphymograph" is Demonstrated to "Elaine Dodge" (Miss Pearl White) by "Craig Kennedy" (Mr. Arnold Daly). Scene in the "Exploits of Elaine," Pathe Film.

In the picture here presented "Craig Kennedy" is explaining and demonstrating the Sphymograph to "Elaine Dodge." Later this remarkable instrument is successfully employed to secure the correct address of the Chinaman, "Wu Fang," who is always scientifically scheming against the science and art of "Craig Kennedy."

The principle of this instrument is based on the fact that if a suspected person, such as a criminal, is successively plied with statements along the line of information desired, that when the correct indication is spoken, that the heart and therefore the pulse will invariably and faithfully momentarily increase in activity. The person's face may not show this (as is well known, of course, in the case of expert criminals), but, thanks to the Sphymograph, which consists of a sensitive microphonic contact arrangement strapped to the wrist of the person suspected, it is made possible for a sensitive galvanometer, seen in the picture, to throw its moving beam of light across the scale, which we also see in the illustration. For instance, in this "movie" story the young lady accomplice of "Wu Fang" is taken to "Craig Kennedy's" laboratory and when he has her placed in the chair the special wrist band is attached and the action taking place is as follows:

The detective repeats numbers on Pell street, where "Wu Fang's" headquarters are supposed to be located, and the series of numbers repeated begin with "1." When he has reached "No. 14" the Sphymograph faithfully records an internal change in the emotion of the young lady by swinging its beam of light from the galvanometer clear across the scale.

Thus it is seen that while the instrument does not read the human mind in the ordinary sense of the word, it truly does read it nevertheless, even though in an indirect yet positive manner.

This may be likened in a general way to the method used in the courts of India

(*Continued on page* 102.)

PASSAIC HAS A WIRELESS CLUB.

At the first meeting of the winter season, the Wegotta Radio Club, of Passaic, N. J., reorganized with three new members. The club started with five members two years ago for the purpose of advancing the knowledge of wireless telegraphy among its members and to bring together the operators of amateur wireless stations in Passaic and vicinity in order to discuss topics pertaining to radio communication and take part in lectures which are given from time to time at the club room.

All the members are licensed by the government to operate stations, and four have been appointed relay stations of the American Radio Relay League, which is an association of amateur operators whose stations make up a chain stretching the entire length of the Atlantic Coast and connect the Atlantic with the Pacific across the northern part of the country. Any of the operators of appointed relay stations may originate messages and thru this series of relay stations, send messages to almost any part of the country.

The Wegotta Radio Club of Passaic meets on the second and fourth Thursday of each month at No. 33 Pennington avenue. The secretary will be glad to hear from any one who is operating a wireless station and wishes to join the club. There are no dues or initiation fees.

The members are: T. E. Ackerman, H. V. Berger, J. L. David, R. Huerdin, C. N. Humprey, E. S. Pearl, W. F. Tense, J. M. Thomson, G. S. Yerbury.

HUGE TELEPHONE AT EXPOSITION.

The accompanying photograph shows a desk telephone set which measures 19 feet high. This gigantic telephone was placed in the rooms of the Western Electric exhibit at the San Francisco Exposition. This telephone in appearance is a replica of the ordinary telephone used every day. Compare it in size with the common desk set shown in the picture. This exhibit is one of the most interesting at the exposition. All kinds and styles of telephone apparatus are shown and demonstrated.

Mammoth Telephone Model Exhibited by the Western Electric Co. at the 'Frisco Exposition.

Uncle Sam's Battleships at Night

Many wonderful electrical sights were produced during the recent review of Uncle Sam's battleships on the North River, New York City. The photograph herewith shows two of the battleships illuminated with electric lights and the gigantic searchlights flashing their powerful beams of light into the night. Some of these searchlight beams were seen many miles distant. Note the illuminated star between the masts on the Battleship "Texas" at the left. Hundreds of horse-power of electrical energy were used in the lighting of the battleships, each one supplying its own power of course.

Photo (C) by International News Service.

Beautiful Effect at Night on Hudson River, New York, When Uncle Sam's Mighty Dreadnoughts Threw Skyward Their Powerful Searchlight Beams.

During their stay for the review a boat race took place at night, the river being well lighted by the searchlights of the fighting-ships. President Wilson was an interested spectator at the race, which was won by the husky crew of the mighty "Wyoming." A single searchlight beam marked the finish line for the boats; rather a novel race marker indeed.

The whole sky was alive with intercrossing beams of light during the evenings and a most beautiful effect, impossible to describe, was produced when, for instance, half a dozen searchlight beams were played in one direction over the sky, while a similar battery of light beams was played past them in the opposite direction. Some of the war vessels evidenced the exercise of great ingenuity in arranging spectacular illumination effects, which were highly enjoyed by the large crowds parading Riverside Drive nightly.

ELECTROPLATING WITH COBALT.

Probably no other paper presented at the spring meeting of the American Electrochemical Society is of such general interest as the one by Messrs. Kalmus, Harper and Savell, dealing with the electrodeposition of cobalt. This is on account of the facts brought out indicating that cobalt may well replace nickel in a great many applications where nickel plating is now used. For the past 20 years nickel plating has been widely utilized to protect other metals, such as iron, from oxidation, and to give a finished surface which would take a polish, have an attractive appearance, and not easily corroded. The performance of nickel has not, however, been ideal. Peeling of the nickel has not been uncommon, and oxidation is not unknown.

Cobalt is in appearance somewhat similar to nickel, but it has a bluish cast. Its specific gravity is about 8.8, or nearly the same as nickel, but its hardness is greater than that of either nickel or iron. This is a very desirable quality in a plating material. The electrical conductivity is slightly greater than that of nickel. As far as its physical properties are concerned, cobalt would no doubt be satisfactory as a substitute for nickel, and would have some advantages over the latter. Its wide commercial use will depend upon the cost of the metal and of the plating operation, the rapidity with which the work can be done, and the adherence of the deposit. The authors of the paper provide some interesting information on these points.

Where suitable plating solutions are used the deposits (on a variety of metals) are found to be firm, adherent, hard and uniform, and can be deposited at a much more rapid rate than is feasible with nickel.

Although wireless apparatus was not fully developed until 1909, it is estimated that over 6,000 lives have been saved by its use.

Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

Münchhausen On The Moon

BANG!!!
Bang! Bang! Bang!!!
Four terrible shots rang out.

A heart-rending moan—a piercing cry. Then a long, ominous silence.

BANG ! BANG !!!

Two more shots more terrible than the first ones.

"Dick!! Dick!!!"

No answer.

"Oh, Dick!!! . . . . . ."

Less answer.

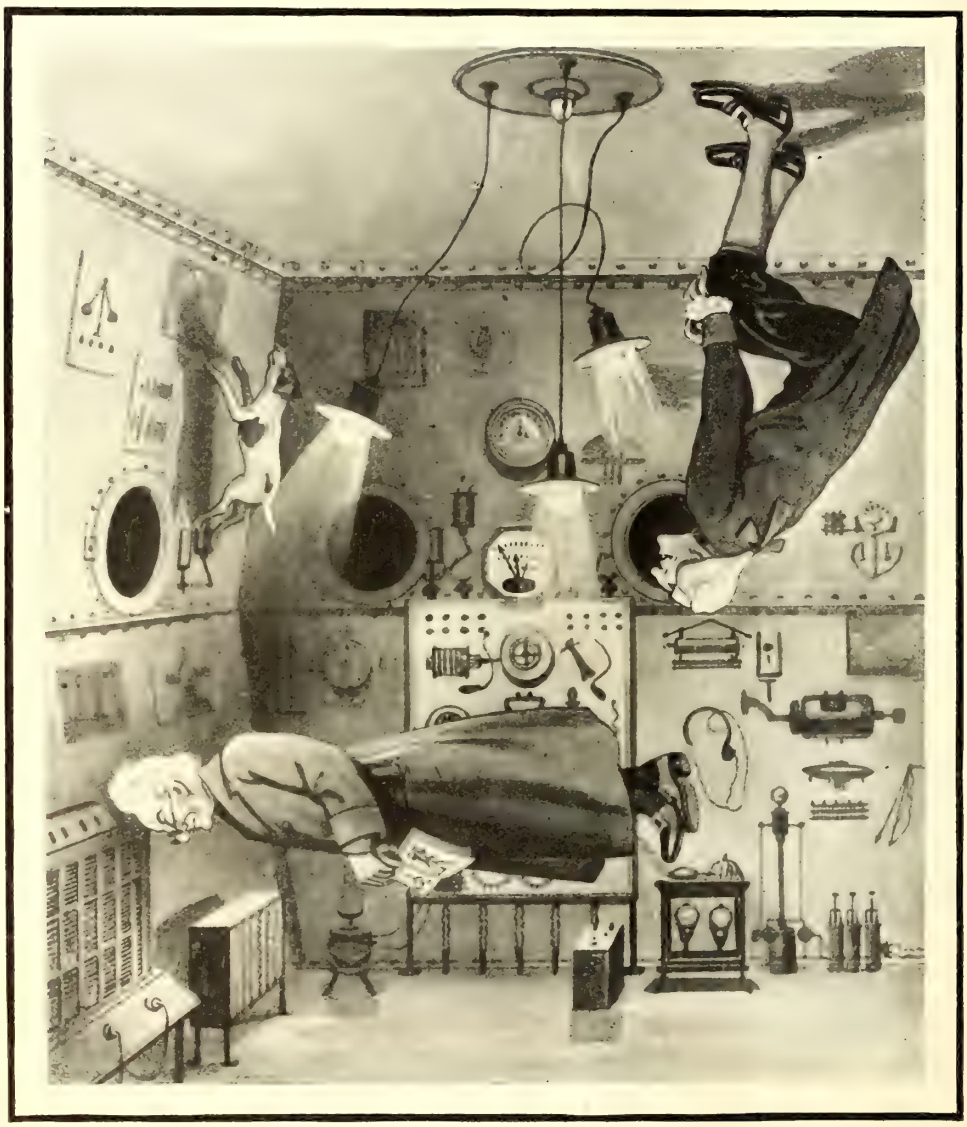
The pine trees on the cliff moaned plaintively in the otherwise oppressive silence. Suddenly a lone owl hoo-hood sharply and simultaneously a flash of lightning illuminated a scene of overpowering dread. I looked on aghast—my hair stood on end. I trembled violently, for what I had seen there was so terrible, so dreadful, so awful that it is impossible for a human being to describe it. For that reason I must refrain.

* * * *

Now, honest, admit it. Was that not a good beginning? You can't deny that it grinned you. The trouble these days is that it is rather hard work to make people read stories. Most stories are not worth reading to begin with. You look at the heading and feel lukewarm. Then you read the first sentence and chances are you immediately form the opinion that the author is an insufferable bone head. At that, you may do him an injustice. He probably is only a second rate idiot. No matter, you won't read his stuff. That's where advertising pays. Put something real exciting at the beginning, even if it has no bearing at all on the rest of the story. Most anything goes, the more mysterious the better. Also—advice to authors whose rent comes due too frequently—the longer you draw it out the better. For the editor—unless he is an old crust and blue pencils most of it—will pay you real money for that dope unless, of course, his sense of humor has gone to smash entirely. Most editors' has.

(*Editorial Note.—We found it necessary to suppress 29 pages of Mr. Alier's manuscript here, as his remarks became entirely too personal and too caustic.—Editor.*)

Now it is a proven fact, supported by much evidence, that people in these days are fond of terminating things once started. Just so with a story. You begin reading a tale, no matter how painful, and once you have spent three minutes on it ninety-nine chances out of one hundred you will see it through to the end. It's like a good "ad." If once you are made to read the headline you probably will read the rest of it. It is the same with a story. Hence I beg your pardon for having taken an unfair advantage of you; in these times of fierce competition "us poor authors" must resort to unusual means, even if it is against all international laws. Just like the German submarine warfare.



Of course, I must admit that the plan has its defects. For with female women it don't work. You see they are foxy. You can't fool them that easy. For they have a cantankerous habit of reading the end of a story first! They laugh up their sleeves—if sleeves are in style that season—and the poor simp of an author who thinks he is going to spring a big surprise on them at the very end has another guess coming!!

So the smart author double-crosses you and puts the real end somewhere in the middle of the book. Then on the last page he arranges for a tearful parting of the hero and the heroine, intimating strongly that the two will never, *never* be married. That leaves you guessing. For if you haven't read the entire story how were you to know that they really got married in the end (in the middle of the book)? But the smart author simply tacked on a few chapters—after the end—showing that the heroine didn't like the hero's liver and that likewise the hero objected to the heroine's gall and to the scent of her face powder. So after things became unbearable they got a divorce—at the end of the book. That's what I call good construction of a story. But to get down to business.

After I had dusted myself off and had made certain that the various members of my anatomy were still on intimate terms with one another I limped off in the direction of my home. As I was not in a hurry I took my time about it. I chuckled inwardly for the good reason that on account of my various bruises I dared not chuckle outwardly; as with General Joffre in France—time worked for me.

But I get ahead of myself again and being too indolent to rewrite this paragraph and putting it ahead of the one above you will have to read it as I wrote it. If you don't approve of that I suggest that instead of reading the first paragraph *first*, to read it *after* the ones that follow this. That will simplify matters considerably.

The facts are briefly these: At the very beginning of this story I have told you how I had been of immeasurable benefit to the human race. I told you how as president of the "American Wireless Mouse-Trap Co." I had rid the country of mice and rats. I had told you how far-famed I was for being the first man to talk all around the globe with my historic wireless telephone. The name of I. M. Alier is linked with the greatest scientists of the world. For that reason I did not think myself immodest when I went to see Mayor Ezrah

... he remained suspended in midair without anything supporting him

Copyright, 1915, by H. Gernsback. All rights reserved.

IS the moon really a dead and barren world as our scientists contend? The most powerful telescopes can only scan the moon's surface, but we know nothing of the interior.

The versatile Münchhausen has been doing some exploring and he tells us a few things, which somehow, sound plausible. Incidentally, do you know that you can jump thirty feet high without much effort on the moon? If you don't, this story will tell you all about it,—and a good deal more.

Coddlemaker, of Yankton, the town of my birth, with a simple suggestion.

There is a small triangular plot at the intersection of Main and High streets. It had come to my ears that a syndicate had been formed to purchase this plot from the city with the object of opening a combination hot frankfurter, flower and barber shop there. As the city would have to erect a monument to my honor sooner or later, and as the site was ideal for this purpose, I went to the City Hall and told the Mayor so. I thought I might as well arrange for the monument during my lifetime.

Mayor Coddlemaker, who had always been a staunch friend of mine, received me warmly. While I explained my mission to him, the color of his usual pink face changed to that of a fresh boiled lobster. Then it went over to a delicate shade of purple. I know now that his inner temperature must have risen from 100° in the shade to 150° in less than two minutes. I began to feel sorry for him that he had neglected to attach a safety valve to himself; it would have been decidedly useful just then. Fearing that His Honor was about to blow up the City Hall with his own person, I tendered him a glass of water. This, however, did not have the desired effect on him, but instead he took on four shades deeper of a beautiful purple and emptied the contents of the glass in my face. Most of it went down the neck of Coddlemaker's secretary, who was working with his back turned toward mine. While I wheeled around to apologize to the secretary, Mayor Coddlemaker, who is an ex-prizefighter, took me by the nap of my neck and spun me around like a top. This seemed to limber him up somewhat, and he became so delighted that he tried me out as a carpetsweeper, my face forming the business end of the sweeper. His Honor then amused himself for some minutes in playing ball with me. I obliged him by taking the part of the ball. My sense of humor being sadly deficient, I failed to see the joke after awhile. I told His Honor so between my rapid trips up to the ceiling and down into the Mayor's fists.

He bellowed something about him and the town of Yankton being made the center of derision with that fool "Münchhausen" story of mine. He playfully added that the papers poked fun at him day and night for letting me stay out of the lunatic asylum. He also mentioned that Yankton had become a permanent feature in all the comic supplements of the country, that on account of my hair-brained story I had definitely ruined not only his career, but the future of the town as well. He gleefully remarked that he had been itching to lay hands on me for a whole month and he thanked me profusely for having satisfied his itch! Whereupon he dumped me in his waste basket and while his secretary held the door open His Honor emptied the waste basket with a flourish. Without waiting to apologize I took a hasty departure.

Now comes the paragraph where I had dusted myself, etc., etc. See above.

On my way home I sympathized deeply with Mr. Galilei Galileo, of Pisa, Italy. He once took a fool notion in his head and told the world that the earth was not standing still, as popularly thought, but that it spun around like a top! Whereupon the world poked fun at him and his fellow citizens playfully intended to burn him at the stake. But Galileo was a good talker and an elegant advertiser. He kept telling them *E pur si muove,* also what an advantage it would be to have the earth spin around, because everybody would get a ride for nothing, and on the trip around people would see lots of new scenery in the universe. He also was careful to tell them that if the earth was to stand still, there would be no seasons any longer and, furthermore, one side of the globe would have a perpetual day and the other side a perpetual night. If by chance Italy should come on the dark side—well, good night!!

So they thought it best to let Galileo have his way and passed a resolution to let the earth spin around indefinitely.

Not that I want to compare myself with Galileo. Far be it from me. I only mention it to show how misguided the world is at times. It was so in Galileo's times and is so now. In years to come my story about Münchhausen will be believed, just as Galileo's preposterous idea that the earth moves is universally accepted to-day.

Just now I am a martyr to a just cause. In due time Yankton will erect that monument for me, or my name is not I. M. Alier.

* * * * * *

Whatever Münchhausen's shortcomings might be, he certainly is prompt. If I were his wife I probably would adore him, for he is always on time to the second. If there were a Mrs. Münchhausen I am sure she never would have to wait with the supper for him. He would be there on the dot, or he would have a mighty good excuse, and be it said here, Münchhausen does not make excuses as a rule.

My clock had just began striking the eleventh hour that evening when, true to his word, Münchhausen "called." There was the familiar, piercing screech in my 'phones, growing louder and louder, and in another second communication between Münchhausen's station on the moon and my own station in the sleepy old town of Yankton, Mass., was once more established.

"Good evening, my dear Alier," it came in clear, deep tones, in that sepulchral voice I had come to cherish, "are you ready for our nightly chat?"

"Indeed I am, Your Excellency," I made haste to reply, "how is your health this evening?"

"Perfect, perfect, my boy. Never felt better in my life. The air up here is so invigorating that I actually grow younger each day!"

"But I thought there was no air on the moon, my dear Baron. I am real anxious to have you tell me all about it."

"Of course, I will tell you, but let me see, where did I stop last night..... Oh, yes..... I believe my power gave out when I told you of my first impressions after the *'Interstellar'* left the earth behind."

The moon overhead was full and we could almost see it grow larger as we rushed toward it through space at an incredible speed. Professor Flitternix and I had calculated that we ought to traverse the 240,000 miles separating the moon from the earth in about 104 hours. This is an average of 2,300 miles an hour and may seem excessive, but in reality it is but a low speed, as speeds go in the universe. The calculation is very simple, too, and well known to astronomers.

Nothing very eventful happened during the trip to the moon. Flitternix was busy with astronomical observations, while I was engrossed with the machinery most of the time.

For the first hour after our departure from the earth we tried to become familiar with the many odd phenomena which presented themselves to us, due to the sudden, almost total, absence of gravity.

The *"Interstellar,"* no longer subject to the attraction of the earth, due to its gravity insulator, was only subject to the moon's gravitational attraction. But as we were some 200,000 miles distant from that body its comparative feeble attraction had but little effect on our bodies in the inside of our flyer.

For, according to the law of gravitation, our 1,000-ton flyer weighed but 110 lbs. at this distance from the moon.

Flitternix was the first to find this out. He had been pointing to the planet Mars with his hand stretched out toward one of the glass portholes overhead. While I looked at this beautiful planet I suddenly heard Flitternix exclaim. He was eying his arm in astonishment. It was still outstretched, but pointing slightly upwards; this is what happened:

On earth his arm would have fallen down to his side of its own accord by the action of gravity, the arm weighing, let us say, 10 to 12 lbs. Inside of the *"Interstellar,"* with practically no gravitation, *his arm weighed less than* 1-10 *ounce;* furthermore, our feet were still pointing toward the earth, where there was no gravitational attraction, due to our gravity insulator. The only attraction coming from the moon overhead, *his arm was pulled slightly upward* by a force of less than one ounce. To bring his arm in its normal position it was necessary for him to use his muscles, which he did with a foolish grin.

We then switched on the entire Marconium netting, thereby insulating us from the moon's attraction also. We were now no longer subjected to any outside gravitational attraction of any kind. Still the *"Interstellar,"* due to its momentum, continued to move forward in space with its original speed.

Some curious phenomenæ were now observed by us. The mass of the *"Interstellar"* being relatively small, its force of gravity was but very minute. When you consider that on earth this globe, with its volume of 600,000,000,000,000,000,000 tons,

attracts my body with 170 lbs. to its surface you will understand that the volume of the *"Interstellar,"* with its 1,000 tons, in accord with Newton's law can attract my body with but an infinitesimal fraction of a pound. *Therefore, practically speaking, all objects within our flyer were without weight.*

For a while we amused ourselves with odd experiments. Thus I would lift up Flitternix with my little finger and place him on my outstretched palm; he weighed less to me than if he had been a child's balloon. Buster, my terrier, became careless and started to jump around, with the result that he went clean up to the ceiling with a thump. His body being elastic he came down with the same speed as he had gone up. There was another thump and he went right back to the ceiling once more with undiminished speed. He simply could not stop any more. He was like a rubber ball bouncing up and down. There being no gravitational force to retard his speed, only the air in the room as well as the friction of his body against the ceiling and the floor; this acted as a slight brake to take up his energy expended originally. It was, however, so slight that after he had bounced back and forth some 200 times, howling frightfully all the while, we took pity on him and stopped him with our hands. After that he became very careful in his movements and we found it wise to imitate him.

We had to move about very cautiously and very slowly; any attempt to walk quick, for instance, was disastrous. Like Buster, it was exceedingly difficult to stop ourselves once started. We could, of course, walk on the ceiling or on the sides of the room with as equal facility as on the floor, for the reason that there is no "up" or "down" in free space. You could lay down most anywhere without danger of falling or even rolling. As our bodies had no weight, it mattered not where we lay down, either. Thus, stretching yourself out, with nothing but the sharp edge of a chair supporting your back, was as comfortable as laying on your cot. You see you weighed nothing, consequently your body could not press down hard on anything, and for that reason you could not possibly feel uncomfortable no matter how you rested.

The most delightful experiment, however, was when I took Flitternix and brought him to the center of the *"Interstellar"* while he was sleeping. Taking my hands away from him he remained, of course, where he was, i. e., suspended in midair without anything supporting him. There being no gravity he could not fall down nor up, for that matter. I then walked on the ceiling and called him. In a few seconds he woke up. I think he must have been the most surprised man in the universe just then. He began clawing the air and looked wildly about him; you see he thought he was still on earth and he imagined he was going to fall down! That goes to show how strong habits and instincts are. In a few seconds, however, he remembered where he was and "sat up." He certainly looked ludicrous sitting suspended there in midair begging me to pull him either up or down. I was so convulsed with laughter at his helplessness and the situation was so droll that I resolved to see the experiment through; for that reason I told him that I refused all assistance. By that time he had become interested in the situation himself and after thinking a little while he began jerking his body back and forward in the fashion of an acrobat on a swinging trapeze. This gave his body sufficient momentum and in a few seconds he had landed laughingly on the opposite wall."

I had listened to the Baron with amazement, but I knew that what he had said coincided with Newton's law of gravitation. There was, however, one point which I had revolved in my mind and which was not clear so I commented:

"What you have just related is certainly exceedingly interesting, my dear Baron, but there is one point I would like you to elucidate: How did you finally effect the landing on the moon?"

"Not so impatient, my dear, I was just coming to that. When at the end of the 100th hour we were but some 600 miles from the surface of the moon, which by this time had become so big that it filled up most of the sky overhead, we switched on the portion of the Marconium netting turned toward the moon. The other half of the netting, which heretofore had insulated us gravitationally from the earth, was then switched off. Now the earth began pulling us again and in a few minutes, with our momentum expended, we were going earthward once more.

Immediately we reversed the currents in the Marconium wire netting, with the result that we fell toward the moon again. In this manner, by manipulating the Marconium netting, I could vary the speed as well as the direction of the *"Interstellar"* at will and within a short while we were

SYNOPSIS

I. M. Alier, an eccentric young scientist of Yankton, Mass., who claims as his own many new as well as startling inventions, far ahead of anything as yet discovered, owns the largest radio-telephone plant in the country. One evening he hears strange noises over his phones and immediately a sepulchral voice is heard. It is Münchhausen, one of the greatest yarn and story tellers of all times. Münchhausen explains how it came about that he did not die in 1797, as popularly thought, and he furthermore gives unrefutable proof that his home is on the moon at present.

Alier wants to know why Münchhausen went to the Moon and how. The latter then explains how Prussia persecuted him and how he went over the the Allies and succeeded in capturing Berlin in a wonderful manner. However, it was not a complete success, so the Baron left Europe for America. He immediately constructs a machine which is to take him into space to the moon. Münchhausen has discovered how to neutralize Gravity by means of Electricity, and he applies this invention to his space flyer, the *"Interstellar."* The machine proves a success; it responds and is lifted with tremendous speed towards the moon.

THIS STORY STARTED IN THE MAY ISSUE. BACK NUMBERS WILL BE SUPPLIED AT 10c. EACH POSTPAID.

but a few miles distant from the moon's surface. We carefully scanned its rugged face with our glasses and we finally decided to make our landing in the plain known to astronomers as *Mare Nubium.* This plain, which in past aeons undoubtedly was part of an ocean, but now devoid of all water, measures several hundred miles across and in some sections it has a very level appearance; moreover it looked sandy like a desert through our telescopes and we decided that we could probably make a successful landing there.

By carefully manipulating the switches controlling the Marconium wires the *"Interstellar's"* wide landing belt finally rolled gently over the volcanic sand of the moon and the flyer came to a dead stop 102 hours after leaving the earth.

It was a supreme moment. We were the first humans to land on the moon and we were naturally quite overcome with emotion for some time. Had I not been the first to conquer space and break away from the earth? Was I not the Columbus of a new world, a world far greater than any explorer ever discovered? Had I not opened the door of the universe that had been locked to all mortals since the beginning of our little world? Had I not thrown off the fetters which chained humanity to its poor, sordid planet for aeons?

I think I had a right to feel elated.

However, hard work lay before us. For centuries it had been the conviction of scientists that the moon was a dead world, devoid of any atmosphere, water and vegetation. Of course, in the absence of these three necessities life could not exist. This we realized only too well, but at best the earth's scientists had no absolute proofs; after all, their conclusions were but theories, although very plausible as well as convincing theories.

Knowing all this we proceeded very carefully. The first test we made was naturally to ascertain if there was any atmosphere on the moon. This test was very simple. We opened a small stopcock leading to the outside and we then listened with strained ears. We had tried the stopcock test out in space midway between the earth and the moon and the air had been drawn out with a loud hiss. While we were listening now there was no hiss, but we could feel the air being drawn out strongly from the *"Interstellar"* when placing the finger on the opening of the stopcock.

From this we concluded that there must be some kind of an atmosphere on the moon, although probably a very rarefied one. This relieved our anxiety immensely and I suggested at once to test the lunar air on Professor Flitternix's canary bird, Pee-Pix.

This was met with violent opposition by Flitternix, who made the counter-suggestion to try it on the dog first, the dog being Buster, my fox terrier. This suggestion was not met with wild enthusiasm by myself either, and a deadlock followed. Finally, however, we drews lots and I lost. Buster therefore was the first terrestrial being to inhale the lunar atmosphere.

With a heavy heart we placed him into the ejector and closed the door behind him; he was now in the air lock. By moving two levers the outside door of the ejector was opened and Buster was in the moon's atmosphere. In another second he had hopped to the ground, anxiously watched by us through the glass plate portholes.

We saw him sniffing at first, whereupon he began coughing violently for some minutes. After that he seemed to become quieter and he commenced to walk around in a curious, excited manner, as if under the influence of a drug.

We could not understand this, but continued watching him with concern. Within an hour, however, he seemed to have become acclimatized and he behaved normally.

I reasoned that if Buster could stand it we could, and I said so to Flitternix. The professor was of the same opinion and we decided to risk it. We opened the door carefully, leading to the outside, drew a deep breath and stepped out. In another second we had landed on the moon.

The first sensation was a strong ringing in our ears and the curious sense of lightness of our bodies. The latter sensation, however, was not new to us, as we had experienced it already in the *"Interstellar,"* due to the absence of gravitation. We now took a careful breath and started to cough violently at once. Nor could we stop it at once. The "air" which we inhaled

(*Continued on page* 122.)

Electricity Helps to Heal German Soldiers Wounds

THE photograph shows a number of wounded German soldiers under expert treatment in a hospital for the wounded. As will be seen, some of the soldiers have their arms inserted in an electric heating oven, and it has been found that this heat treatment acts very remarkably to remove stiffness from the joints and muscles.

The temperature of these ovens is very carefully watched by means of the thermometers, and the soldiers receive this treatment at regular periods each day until they are thoroughly well and ready for the front again.

The electric ovens shown have been used considerably in hospitals and sanitariums with great success. They comprise an electrical heating element composed of a wire or ribbon resistor, which becomes heated to different degrees when the electric current is applied, depending upon how the different sections of the heating element are connected to the line wires.

As seen, each heater has a marble switchboard on same which contains the different switches for adjusting the amount of current used, and which, in turn, permits any degree of heat wanted to be had readily.

Some of the electrical ovens for this purpose are much larger than the ones here illustrated and are adapted for heating the entire leg, etc. Also some of the ovens are built in such a shape that the abdomen or back of the patient can be heated as well.

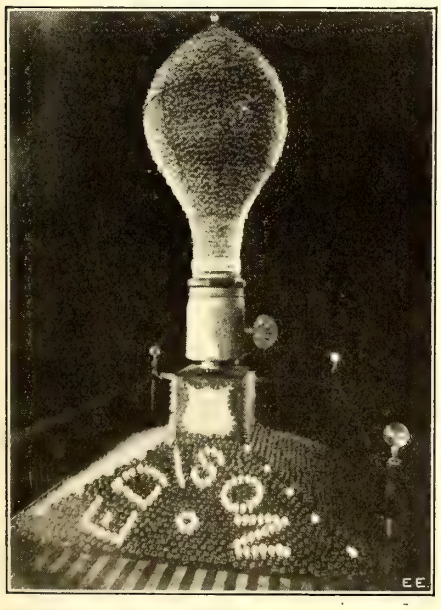
The Kaiser's Wounded Soldiers Make Use of Electric Ovens to Limber Up Their Stiffened Muscles.

LOCATING SHELL FRAGMENTS IN WOUNDS.

A method of localizing shell fragments or other pieces of magnetic material in the human body, which has recently been tested in France, is noted in the *Engineer*. A powerful alternating current electro-magnet is brought near the region affected, and the presence of a magnetic body within the flesh is indicated by a perceptible trembling of the surface at the immediate locality. By feeling the flesh the surgeon can easily find the spot where the trembling is strongest, and can thus locate the fragment of projectile with considerable accuracy.



The action of this alternating current method of locating pieces of iron or steel which may become buried in the flesh, is based upon electro-magnetic induction set up in the iron particles or fragments, due to the powerful alternating magnetic field of flux created by the A.C. magnet.

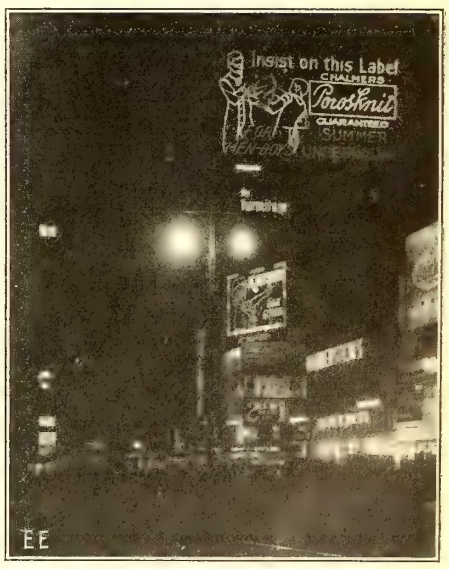
The pieces of iron thus manifest magnetic qualities, owing to the current set up by induction in them and, of course, will also manifest movement, the same as the action taking place in an A.C. motor, etc.

Other methods in use consist of the X-Ray, the Induction Balance, etc.

ELECTRIC BULB COMPOSED OF 16,000 LAMPS.

A huge electric lamp, herewith shown, was built for the Cincinnati Exposition in 1888. This lamp consisted of a form or frame made of wire and having 16,000 electric lamps fastened on it. The "filament" consisted of a 3-inch pipe bent in the form of a regular filament, and red electric lamps were built upon it. When the red lamps were lighted their rays penetrated the glass of the outer electric bulbs and gave the appearance of a *real* gigantic lamp. This photograph is from the wonderful collection of William J. Hammer, the eminent electrical engineer and for many years the associate of Thomas A. Edison in the development of the incandescent lamp.

An Early Edison Exhibit in the Form of a Monster Lamp Bulb Containing 16,000 Regular Size Bulbs.

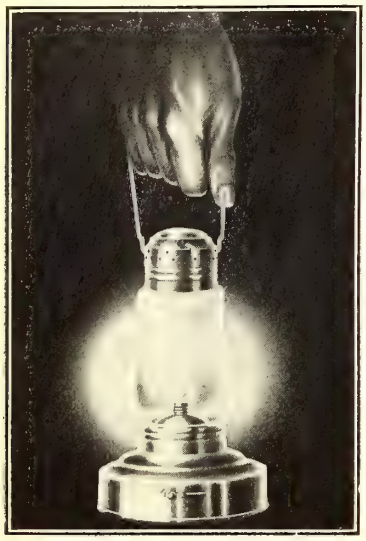


SELF-INDUCTION OF SOLENOIDS OF APPRECIABLE WINDING DEPTH.

At the April 23 meeting at the Imperial College of Science, London, a paper by S. Butterworth was read having the above title.

The existing formulæ for coils of this type, viz., those of Rosa and Cohen, of the U. S. Bureau of Standards, Washington, D. C., are shown to be inaccurate, the error amounting to one-fifth of 1 per cent. for the best formula when the winding depth is one-tenth the diameter of the coil. For greater winding depths the error is larger. The inaccuracy in Rosa's formula is due to the neglect of curvature in correcting for thickness, while in Cohen's formula the error is due to the approximate method of development. New formulæ are developed by methods which are free from such approximations, and which apply to any coil for which the length is greater than twice the diameter, and the winding depth is less than one-tenth the diameter. These formulæ are capable of giving eight-figure accuracy. Simplified formulæ are also given which are suitable when only four-figure accuracy is required.—*The Electrican*, London.

NOVEL "BOXING BOYS" ELECTRIC SIGN.



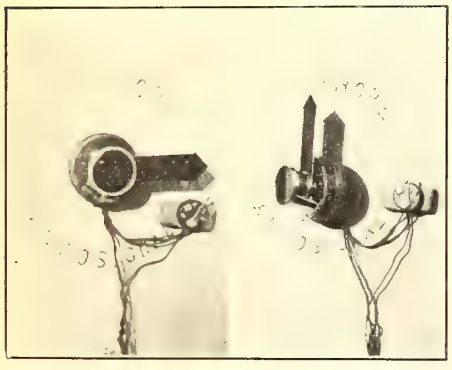
A spectacular electric sign, having rapid action to hold the attention of the public, is shown in the illustration herewith. This sign is one of the many marvelous attractions along the "Gay White Way" of New York City.

Electric Sign in New York City Featuring the "Boxing Boys" of Porosknit Fame.

THE FRIAR'S ELECTRIC LANTERN.

A new electric lantern herewith illustrated was recently put on the market. The lantern has the shape of an old-style oil lamp in which the oil fuel has been substituted by the modern dry battery, thus

Neat Electric Battery Lamp Known as the "Friar's" Lantern.



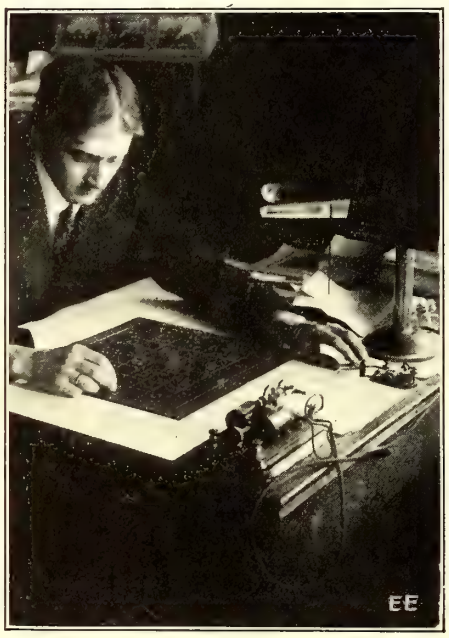
eliminating the accompanying dirt and danger occasioned by the use of oil.

The battery of this lantern is guaranteed by the manufacturer to give five hours continuous and 10 hours intermittent service, and while the fuel is not quite as cheap as in the old-style oil lantern the compensating features of neatness and safety in the new Friar's lantern make the difference in cost well worth while. A handy switch on the base enables the user to turn the light on or off.

A telephone call is ordinarily answered to-day in from three to five seconds. In the first exchanges it required from two to three minutes, and often a great deal longer. Such service would stagnate the present business world.

ELECTRIC SIGNAL FOR AUTOMOBILES.

An electrical signal to show the direction in which an automobile is to turn at street corners has been invented by a California man. An arrow-like indicator arm, rotat-



Two Views of New Electric Automobile Signal.

able from a normal vertical position to either right or left and operated by electromagnetic control, indicates the direction to those in the rear that the vehicle is about to veer off in. An electric lamp at the hilt of the reflector blade adds to the usefulness of the device at night.

PLAYING CHECKERS BY TELEGRAPH.

Exciting checker games by telegraph are not uncommon, and after the heavy work in the depots of many Western railroads has been transacted and the weary night operators return to their rooms to report the train either departed or passing by, the sounders click off mysterious numbers, which recently have been solved as checker tournaments by wire, the contestants being telegraphers located many miles apart. Many times checker games are in action over entire railroad divisions.

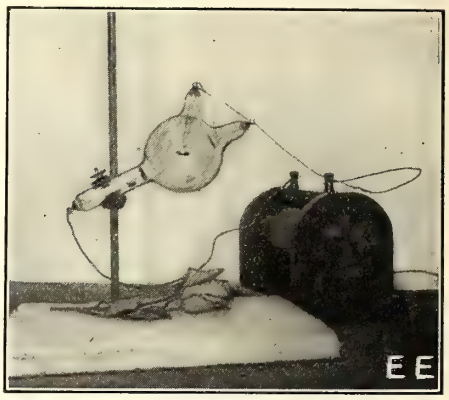
The accompanying photograph shows the operator putting the telegraph to good advantage in a very exciting game. The system used is very simple. An ordinary checker-board is marked from 1 to 32, inclusive. Two sets of checkers are used by each operator. At the start of the game the operators decide on who is first to move. The first mover clicks off in the Morse code as follows: "14 to 19, or 13 to 18," or vice versa, or according to the side of the board he chooses. Usually the operators decide in advance whether they have selected the red or black. When a king is made it is flashed over the wire, and although the contestants are far apart,

Playing Checkers by Telegraph.

yet the game is as interesting as if they were seated opposite each other at the same table. Frequently other operators along the line put their boards in action and *watch the game* by following the numbers as they come over the wire, moving the checkers on their boards accordingly. The operators say it is a great pastime.

TIFFIN RADIO CLUB.

A new radio organization was organized recently in Tiffin, O., with five charter members and has great promise of rapidly enlarging its membership.



The officers elected are: President, John Grossman; vice-president, Paul Frederick; secretary and treasurer, Harold Buck.

It is desired that all wireless experimenters living within communicating range of this club correspond with the secretary in order to widen the influence and activities of the organization.

Black asphaltum is excellent for painting wireless instruments on account of its good insulating qualities.

THE STUDY OF FLOWERS WITH THE AID OF X-RAYS.

The applications of the X-rays to the study of phenomena invisible without their aid continually increase in number. One of the latest scientific uses found for these rays is in studying the inner structure of flowers and fruit buds. In some respects this is a better method than dissecting for

Studying Flower Growth and Structure by Means of the X-Ray.

the study of certain parts of plants, especially while growing.

The photograph here shown is that of a rose being examined by the aid of X-rays which are produced by the X-ray tube placed above and connected to a high-tension induction coil. The flower is placed on a box, which may be a plate-holder, containing the photographic plate.

Although most electric motors contain iron cores in their magnets some motors do not have any iron in them, as those, for instance, used in recording watt-hour meters.

It is now possible to transmit and receive eight distinct telegraph messages over a common circuit of two wires.

A FLASHLIGHT FOR THE PENCIL.

While there have been many novel applications made recently of the electric flashlight, probably one of the most useful for literary people, such as reporters, etc., is that shown in the illustration, and embodying a complete miniature electric flashlight with battery, adaptable to a pencil.

A simple switch on same enables the user to utilize the light whenever desired. This device is extremely small indeed and can be carried in the pencil pocket without any

This Ideal Pencil for Reporters Carries a Small Electric Light of Its Own.

undue bulging. One battery will last a few months with ordinary use. Such a pencil light is just the thing for taking down notes in theaters, where the auditorium is darkened; besides, it has many other useful applications.

LUMBERING TELEPHONE SIGNAL SERVICE.

By Frank C. Perkins.

The accompanying illustrations, Figs. 1 and 2, show the telephone refinement of the signaling systems used by lumber producers employing the long haul or pull boat method of skidding. This is said to be the quickest and only positive mode of signaling between drum man and tong man, and it is pointed out that instantaneous and accurate signals by telephone assure increased efficiency and decreased expenses.

It may be stated that every large lumber producer in the country, especially those using the out-haul system of logging, either the ground or cableway skidders, has been sorely pressed for an efficient method of signaling, which would be both positive and instantaneous, between the tong man in the woods and the drum man on the skidder. Every conceivable way has been tried, as, for example, the whistle signal, in which a string or cord is dragged out into the woods and is pulled to blow the whistle on the skidder. This has also been tried with a bell instead of a whistle.

Railroad signals were experimented with and, last of all, hollering was tried. This was done by placing a signal man or flag man near the tong hookers, who could signal to a man located near the engine, who in turn would signal the engineman. After numerous trials, each was thrown aside as useless. Still, some companies are doing the best they can by combining the railroad and the hollering signals, but these are far from satisfactory. Some companies have even given up the out-haul idea, on account of the lack of proper signaling apparatus. Every lumberman knows just how slow and inaccurate these modes of signaling are, especially where the out-haul skidder is in use.

There has now been designed special telephone instruments which have solved the problem of signaling for the lumberman. By means of this system the tong man and drum man can talk to each other at all times, regardless of whether the skidder engine is running or not, and it works successfully whether the tong man be 100 feet or 4,000 feet from the skidder.

At Left: Fig. 2. Lumberman Using New Type Telephone Especially Designed for the Purpose.

Below: Fig. 1. Lumberman's Type Telephone Recently Put on the Market.

The telephone service consists of a steel reel or drum, placed or mounted on the skidder, together with the instruments. On the drum are 2,000 to 4,000 feet of strong heavily insulated wire made for this purpose. There is continuous connection at all times through this wire by means of a brass commutator.

The head telephone set is connected by a plug and jack, and can be disconnected instantly. This set is very light and leather-covered to protect it from steam, grease and sparks, and is never in the way of the drum man when running the engine, and allows him to have both hands free. No batteries are used with either set, so the cost of maintenance is practically nothing. They work on the permanent magnet system. Either party can call. Should the tong man desire to talk to the drum man while this plug is out, he can be signaled by pushing the button and turning the crank on the field set, which will ring a bell inside the skidder set, notifying the drum man that he is wanted. He can then plug in and talk.

ELECTRICAL NOVELTIES FOR THE BANQUET TABLE.

By Felix J. Koch.

Down Cincinnati way hostesses *do* seem to possess the knack of getting up novelties—things that will appeal and yet which are different from anything anyone may have seen, just exactly the same theretofore.

So not long since, when young Jack Roosa was to celebrate his graduation from the medical college at the Queen City—and this with a banquet to his friends—his big sister, to whom he left arrangements, conspired with the toy dealers and the electricians of the town, with results as shown in the picture.

Up at the table center there was a great bowl of cosmus—just a plain vase, it seemed—and you never would guess that the base of that vase was an inverted bowl, or cave, within which a central plug could be placed for wires radiating out from between the grooves of the design on the vase. Five minutes' survey of the cheapest vases in any china store will supply you with such, of course.

These little electric wires—neatly insulated with green, that could be concealed beneath the flattened ferns on the cloth or among the lines of smilax—led, each in turn, to an inexpensive skull of papier-mache, supplied by the toy store, and there lit up a wee little bulb light, alternate red, then deep green.

These skulls in their turn were placed upon paper napkins of Hallowe'en patterning—witches, dark nights, Jack o' lanterns—likewise from the toy store. Otherwise, ferns and smilax, a carnation for boutonniere at each place, and the table was done.

When ready for serving, all lights save those in the wee skulls were extinguished. The little lamps cast their subdued rays through the hollow eyes on the place-cards beneath; and by aid of these, and these only, the young "medicos" found their places and enjoyed their first course—the initial one of a season of revel and fun. The picture shows the table ready for the guests.

Electrically Lighted Skulls, Figures, etc., Make a Novel Banquet Table Display.

A NEW ELECTRIC DISHWASHER.

A new electric dishwasher has recently been placed on the market.

Fig. 1 shows the dishwasher permanently connected in a kitchen. On the shelf at the left a rack of dishes is seen ready for washing. At the right a basket is shown in which glasses and silverware are placed.

In Fig. 2 the interior of the machine is shown with the rack of dishes and the basket containing the glasses and silverware in position.

Fig. 1. Electric Dishwasher Installed in Modern Kitchen.

Beneath the circular tank a ¼-horsepower electric motor is direct-connected to a small centrifugal pump, which forces hot soapy water through a perforated pipe in the center of the machine and out over the dishes until they are perfectly clean.

The dishes in the machine being above the water level and in a vertical position, the water drains off, while the combined heat from the direct contact with the hot water and the contained heat in the tank dries the dishes.

During the entire operation of washing, rinsing and drying, which takes less than five minutes, the dishes remain stationary in the machine, thus eliminating any danger of breaking or chipping.

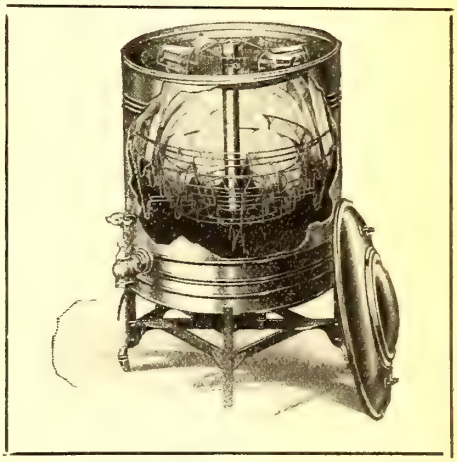


Fig. 2. Showing Dishes Placed in Electric Dishwasher.

AN "ATTRACTIVE" OLD MAN.

Different from the immortal "man with a hoe" is the man pictured in the illustration, who is kept busy walking around the yards of the Willys-Overland Co. at Toledo, O. By means of his trusty steel magnet secured to a shovel handle he man-

"The Man With a Magnet" Picks Up All the Nails, etc., in a Western Auto Plant's Yard.

ages to keep the roads about the auto plant clear of small iron or steel fragments which might puncture the auto tires. The magnet picks up all the nails, chips, etc., and which are then removed from the magnet and deposited in the pail.

HOW TO PRESERVE YOUR ELECTRICAL EXPERIMENTER.

No doubt many subscribers to *The Electrical Experimenter* keep the back numbers for future reference for the purpose of constructing instruments described in them, etc. Frequent handling while looking up the desired information soon renders the magazines ragged and worn.

To prevent this, get some manila paper folders, such as are used for music, and place the magazines in them. One or more copies may be put in each folder, as desired. Mark each folder so that you can see which copy or copies are enclosed. Then arrange the folders in the order in which the magazines were published.

This method, in connection with a card index, saves considerable time in hunting up any instrument or apparatus described in any issue, at the same time preserving them. Contributed by

WILLIAM H. SCHMOLL.

Dry cells should never be connected up with accumulators; the effect of the arrangement might be expected at first to light the lamps to an unusual brilliancy. Very quickly, however, the dry cells will become exhausted and then they will act as a dead resistance to the passage of current from the storage battery to the lamp.

A PHONOGRAPH-TELEPHONIC LECTURER.

An exceedingly ingenious phonograph-telephonic lecture system has made possible a wonderful reproduction of the Panama Canal at the Panama-Pacific International Exposition. This remarkable replica of the canal gives the visitor a more intimate perspective of the entire Canal Zone than is perhaps possible by a trip through the canal itself. This canal, in miniature, covers an area of four and one-half acres, and is accurately and minutely made to the smallest detail.

In order to facilitate the inspection of this gigantic model, an endless moving platform circumnavigates it. The platform is 1,147 feet long and consists of 144 cars, which are propelled by electric motors. Each car is equipped with seats for the passengers, and each seat is equipped with a pair of *Western Electric* watch case 'phones attached to an adjustable handle, through which one can hear a continuous descriptive lecture as the trip is made around the canal model. Fig 1 shows the type of 'phones used. This special type of handle was designed so that the spectators would not be obliged to hold their arms in an uncomfortable and tiresome position, and to prevent the necessity of removal of hats on the part of the ladies. Fig. 2 shows the telephone equipment installed on one of the passenger seats.

A telephone transmitter is connected to an Edison phonograph, which contains the lecture and reproduces it into the transmitter. This transmitter is connected to 42 receivers, and thus 42 passengers are connected with one phonograph. There are four of these units in the system.

This is the modern way of lecturing.

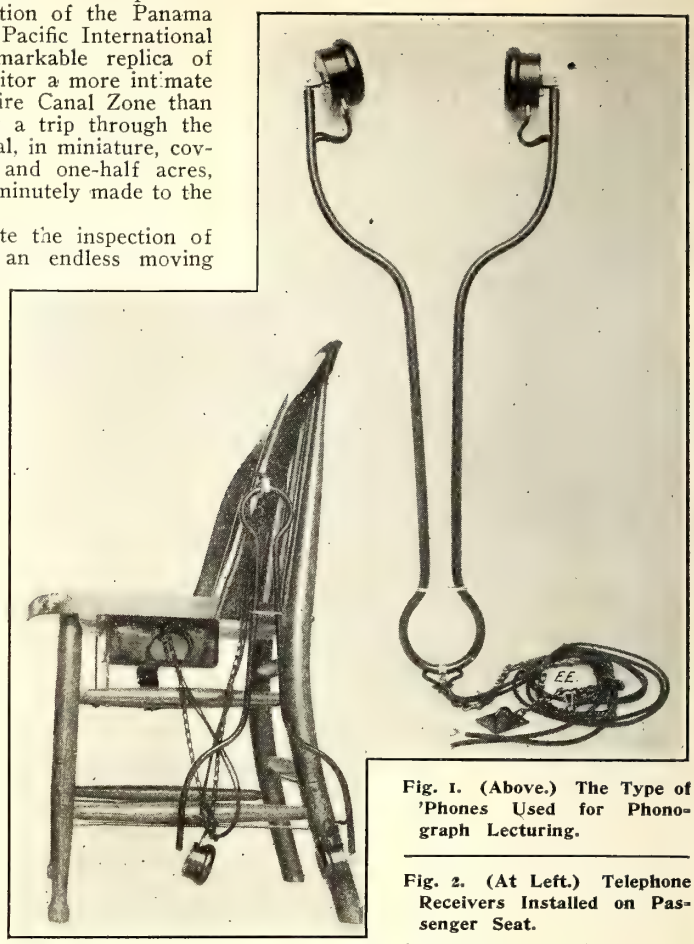

Fig. 1. (Above.) The Type of 'Phones Used for Phonograph Lecturing.

Fig. 2. (At Left.) Telephone Receivers Installed on Passenger Seat.

AN ELECTRICALLY HEATED SHOE-TREEING IRON.

The electrically operated shoe-treeing iron or "Calorel" re-laster, as it is called, which is illustrated herewith, is designed for use in retail shoe stores and can be operated from an ordinary lighting socket. It consists of three parts rigidly fastened together—the highly polished brass tip, the heating element, and the handle, which is of nickeled-steel wire. The brass tip weighs 1 pound and is able to store a comparatively large amount of heat. The device is equipped with 10 feet of flexible cord and a detachable plug, and takes 80 watts. At the average price for electric current it can be operated for less than half a cent per hour. It should be of great service to all shoe dealers in aiding them to make shoes look and fit their best.

A Flexible Electrically Heated Re-Laster for Shoes.

TO DISTINGUISH DIRECT FROM ALTERNATING CURRENT.

In case of uncertainty the following very simple method may be used to ascertain whether an electric lamp is supplied by direct or alternating current. Stand at some distance from the lamp and wave a stick to and fro between it and the observer's eye. If the current is direct (continuous) no distinct image of the stick will be seen, but only a blur. But if the current is alternating there will appear to be a number of sticks. This is due to the fact that an alternating current reaches a maximum and falls to zero in very rapid succession. A similar effect may be observed in a darkened room if an induction coil with bright sparks passing between the terminals is substituted for the lamp.

The energy freed by cooling one spoonful of water one degree would operate a telephone for ten thousand years. This baby current of electricity must take a voice 3,400 miles, and it cannot be increased or its power to transmit speech is gone.

LOCATING BURIED PIPES ELECTRICALLY.

Where will we strike an underground pipe? The haphazard plan of drilling and chopping the soil has never been satisfactory, and some means of determining the presence of underground pipes before boring into the soil have been sought ever since underground pipes have been in general use.

An apparatus which will determine the exact location of metal pipes, conduits, cables, etc., that are 12 feet or less underground is shown in Fig. 1.

The apparatus consists of an induction coil delivering a medium voltage, batteries, telephone receiver and an exploring or feeling coil.

The apparatus is used as follows: Terminals of the instrument are attached to a pipe at some accessible point. Then the operator holds the exploring coil in his hand as shown in Fig. 2, and holds the receiver to his ear. He now walks about, holding the exploring coil near the ground. The vibrator is then started on the coil. The humming of the vibrator is heard in the receiver, but as soon as the operator comes anywhere within the area enclosed by any pipes the humming in the receiver will decrease, and over the pipe no hum at all will be heard. The operator then knows that the pipe is within this area where he stands.

Fig. 2. Proper Method of Handling Exploring Coil When Tracing Path of Pipe.

The whole device is portable and can be carried about readily. It operates on batteries and sells at a reasonable price.

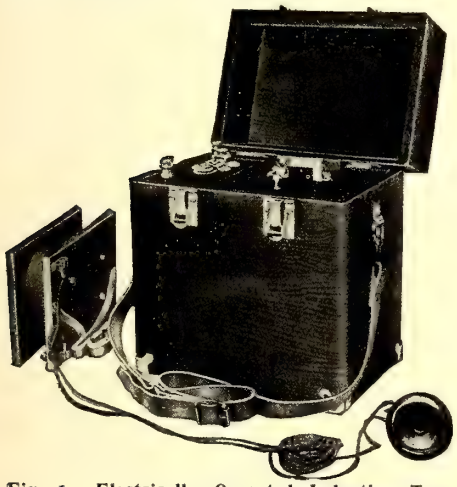

Fig. 1. Electrically Operated Inductive Type Buried Pipe Finder.

Russell Hoffman, of New Lexington, Ohio, writes us:

"I received my first issue of *'The Electrical Experimenter'* and think it is the best magazine I ever read."

A. S. Burleigh, of Great Falls, Mont., writes us as follows:

"*The Electrical Experimenter* has sure been worth 50 cents during the past year."

Tungsten lamps give about three times as much light for same current cost as carbon lamps.

Liquid air boils water and burns violently when ignited by a match.

THE SUN, THE BASE OF ALL ENERGY.

In this age of scientific wonders, we are perhaps, at times, apt to forget where the base of all energy in various forms is located. This central dynamo, if so we may term it, is the Sun, which is constantly giving off energy in the form of very rapid heat waves, transmitted through the medium we now call the ether. The ether transmits light, heat, wireless and other waves by vibration according to the theories now accepted, and when a body intercepts these waves they manifest themselves in one form or other.

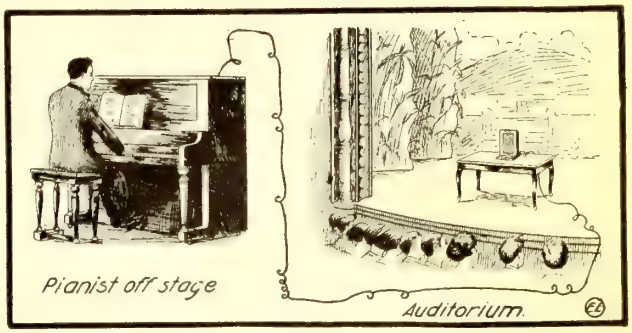
Says D. Albert Kreider, Ph.D., of Yale University: "All heat, natural or artificial, is traceable to the sun as the original source. By the ancients the sun was regarded as a huge ball of fire.

When one remembers what a small speck in the universe the earth is, and how far it is from the sun, it will be evident that the earth can intercept only an infinitely small portion of the total heat which the sun radiates. Nevertheless, at the earth's surface this is at the rate of about 7,000 horse power per acre! How then can such an enormous loss of heat by the sun, without cooling, be accounted for?

The answer is that the sun is constantly contracting.

Anyone who has ever pumped up a bicycle tire knows that the compressing of a gas, heats it. Now the sun is still gaseous and is compressed by its own enormous force of gravitation. This force is 27.5 times as great as that of the earth. To illustrate: a person whose weight here is 110 pounds, at the surface of the sun, would weigh 1½ tons. But the sun can contract only as it loses heat; and thus it provides a nice balance of forces which maintains the temperature. Obviously this contraction can not go on indefinitely. It has, however, gone on for hundreds of millions of years in the past and may continue for millions of years to come.

The sun is an enormous mass, 866,500 miles in diameter, which is 109½ times the diameter of the earth. Calculation has shown that a contraction of only 250 feet per year is sufficient to account for all of the heat energy which it radiates. At this rate the contraction could continue for 9,000 years before the most powerful telescope could detect the consequent change in its diameter. It must be remembered that the earth is 93,000,000 miles from the sun.



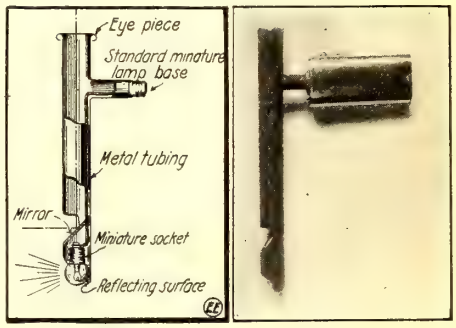
FINAL CALL

Beginning with July 1st the subscription price of THE ELECTRICAL EXPERIMENTER goes to $1.00. *It is to your interest to subscribe now while the price is so low.*

THE ELECTRICAL EXPERIMENTER is the greatest value today in Electrical Literature. If you intend to subscribe to it, do it now. One year, 50 cents; 2 years for $1.00, *3 years for* $1.50. *5 YEARS for* **$2.00.** (*Foreign postage to be added.*)

THE MACROPHONE OR LOUD SPEAKING TELEPHONE.

Loud talking telephones are always in great demand for various purposes, one use for them being illustrated in the sketch here presented, where piano music is transmitted electrically over a wire to a theater, or *vice versa*, etc.



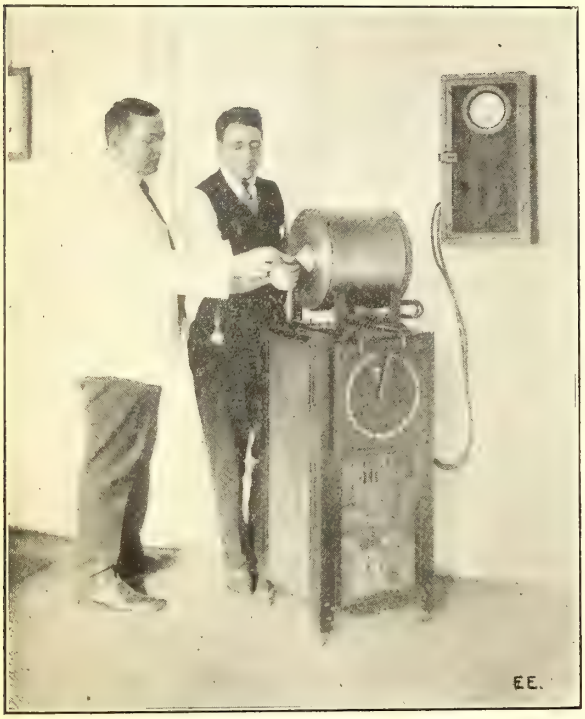
Loud Talking Telephonic Device Adapted to Piano Recitals, Etc.

The Macrophone loud speaking telephone is a radical departure from the usual form of such apparatus, as the diaphragm is composed of a thin wooden panel suitably supported in an acoustic sense. This wooden membrane is caused to vibrate and sets up sound waves by a powerful set of electromagnets acting on a lever secured to it. The lever is given resiliency by means of a strong rubber band, and thus no rigid connection exists between the diaphragm proper and its actuating magnets.

This loud speaker will transmit regular speech, music, phonograph sound, etc., and operates on eight dry cells, which will last for a period of three to four months. A microphone is generally used in the circuit, but for piano music transmission, such as shown here, the wooden diaphragm is rigidly connected to the piano sounding board by a wood pin glued between them. The Macrophone acts as transmitter or receiver.

AN ELECTRICAL INSPECTOSCOPE

A handy and neat instrument for inspectors, automobilists, engineers, machinists and others is the Crane inspectoscope, illustrated by the half-tone and detail sketch.



Sectional View and External Appearance of the "Inspectoscope," Useful for Looking Around Corners With.

It works on the principle of optical reflection, and, as the details indicate, use is made of a small flashlight lamp placed at the base of the tube. Hence in dark corners the lamp, which is lighted by screwing the attachment plug into any flashlight case, illuminates the object, and its image is viewed by placing the eye against the eyepiece at the top of the tube. The device is small in size and carried readily in the coat pocket. It is extremely useful in locating oil and carbon deposits in gas engine cylinders, small parts, screws carelessly dropped into some intricate machine, wires being 'fished" under flooring or in walls.

POWERFUL MAGNET DRAWS STEEL FROM BODY.

The removal of pieces of shrapnel, steel-jacketed bullets, steel shavings, etc., by the use of powerful electromagnets in hospitals abroad has been acclaimed by many newspapers as the very latest application of science to surgery. It is interesting to note that the Westinghouse Electric & Mfg. Co. has installed in the relief department of its East Pittsburgh Works a magnet for removing metal imbedded in the flesh, which is one of the most powerful in the world.

Powerful Electromagnet Draws Iron or Steel Chips From Fingers, Eyes, Etc.

The magnet is mounted on a box containing the resister, which is used to regulate the amount of current flowing through the coils. It requires 4,000 watts for its operation, or enough power to supply 100-32 C. P. Mazda lamps.

It is not an infrequent occurrence for steel and iron workers to get bits of metal in their eyes or hands. Previous to the installation of a magnet the only means of removal was by probing, a method which is as uncertain as it is painful. Since this electromagnet was put in operation it is a very simple proceeding to extract such particles. The portion of the body in which the foreign particle is embedded is placed near the pole tip of the magnet, the switch closed, and the magnet does the rest. The pole is removable, a number of different shapes being supplied for various classes of work.

It is very common for flying bits of metal to lodge in the eye. Should they strike with force enough to become imbedded the removal, without the aid of a powerful magnet, is apt to be difficult as well as painful. The protecting coating of the eye must be cut, and there is danger that instead of removing the particle it may be pushed further into the eye. When the foreign body is once within the eyeball it is properly a case for the specialist.

Steel workers frequently have their hands punctured with minute pieces of metal, which become imbedded under the calloused skin. If these bits are allowed to remain the wound is likely to become infected. The use of a powerful magnet insures the removal of all traces of iron from wounds in the hand or any other part of the body. Some remarkably small pieces have been extracted in this way, one recently recovered being not one-twelfth of the thickness of a delicate needle.

Dr. C. A. Lauffer, medical director of the Westinghouse company, relates a number of instances in which the magnet has proved invaluable. Among these is the rather amusing case of a workman who attempted to drill one of his own teeth. The drill broke off about half an inch from the end and remained in the cavity and it seemed as if the only way to remove the drill would be to pull the tooth. However, a special extension was made and fitted to the magnet pole. As soon as the extension was brought in contact with the drill and the current switched on the drill was immediately drawn out.

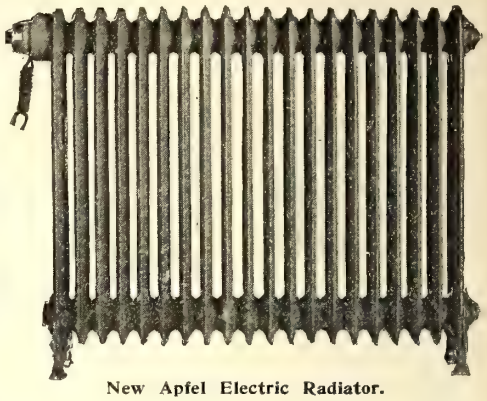
The American Telephone & Telegraph Co., and associated and connected companies are now giving service to 100,000,000 people by means of 90,000,000 telephones and 21,000,000 miles of wire.

The voice by telephone travels from New York to San Francisco in 1-15th of a second, traveling at the rate of 56,000 miles per second. The voice of a man speaking in New York is heard in San Francisco three hours earlier, that being the difference in the standard time of the two cities.

AMERICA'S VICE-PRESIDENT TRIES ELECTRIQUETTE.

By FELIX J. KOCH.

No, there are no heralds to proclaim, with sonorous: "Oh yez! Oh yez! Make way, * * * make way! The most excellent, the Vice-President of the United States"; but, instead, you hear the jingle of a little electric call-bell, then the soft whirr of rubber tires, and, lo, the Vice-President of the United States of America has gone by in an electriquette.



Of course, chances are, you do not know what an electriquette happens to be. Jack Roosa, who's been down to San Diego to see, tells us that it is a comfortable, two-seated sedan chair, fitted with much the same apparatus that drives an electric automobile. Only, it is simpler—so very much simpler that a mere child can operate it. So tired visitors to the big fair seat themselves in it, start on their journey and are soon whisked to where-so-ever they'd go; enjoying a much-needed rest mayhap the while.

Vice-President Marshall in an "Electriquette."

ELECTRICALLY HEATED RADIATOR.

A new electrically heated radiator has recently been put on the market. The heating elements are inserted through the bottom and top of the radiator. This element is divided into several sections and is connected to a multiple-pole switch which can either be attached directly to the radiator, as shown in the illustration, or placed at any convenient point desired. The consumption of energy based on a square foot of radiating surface is 30 watts to 35 watts on high heat, 15 watts on medium heat and 8 watts on low heat, giving a radiating temperature under normal weather conditions of approximately 200 deg. Fahr. on high heat. The amount of heat generated is controlled automatically by means of a thermostat.

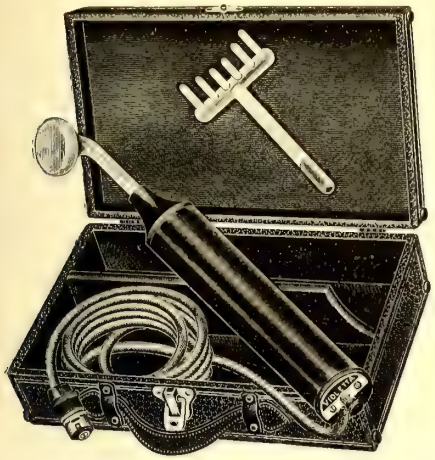
New Apfel Electric Radiator.

A NON-MAGNETIC YACHT.

The "Carnegie," the yacht employed to make a magnetic survey of the earth, has just reached Honolulu after having passed through the Panama Canal. From there the staff will make magnetic observations in the South Pacific Ocean. These include the magnetic declination, the horizontal dip and the intensity of the magnetic field, together with studies of atmospheric electricity. The "Carnegie" is non-magnetic, being built of wood with locust spikes and copper sheathed below the water line. The auxiliary engine and all stoves are of copper; the 1,400-pound anchor is bronze; all metal fixtures are of non-magnetic material; all-brass lamps being used throughout.

FOR WOULD-BE CONTRIBUTORS.

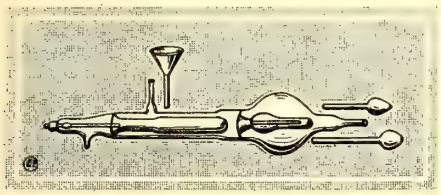
If you've got a thought that's happy,
  Boil it down.
Make it short and crisp and snappy—
  Boil it down.
When your brain its coin has minted,
Down the page your pen has sprinted,
If you want your effort printed
  Boil it down.



Take out every surplus letter—
  Boil it down.
Fewer syllables the better—
  Boil it down.
Make your meaning plain; express it
So we'll know, not merely guess it;
Then, my friend, ere you address it
  Boil it down.

Boil out all the extra trimmings—
  Boil it down.
Skim it well, then boil the skimmings—
  Boil it down.
When you're sure 'twould be a sin to
Cut another sentence in two,
Send it on, and we'll begin to
  Boil it down.

—*"Gumption."*



MINIATURE HIGH FREQUENCY SET.

One of the smallest practical high-frequency machines, and suitable for either direct or alternating current circuits, known as the *Violet'a*, is illustrated here-

Above: New Portable High Frequency Set Which Fits the Hand.

Below: Ozone Generator for Use With Set Above Shown.

with. This apparatus is so small it can be held in the hand while in use for generating high-frequency currents. The complete outfit, suitable for use by anyone, includes several treatment or application tubes exhausted to different vacua.

Owing to the special design of the vibrating interruptor on this device the action of same is very steady and uniform.

For those desiring to take ozone treatment a glass ozone generator is furnished at slight extra cost. It is seen in the illustration, and this instrument generates enormous quantities of ozone, which is purified by passing through a mixture of pine-needle oil and eucalyptus, and is injected into the lungs in the form of vapor by agitating the rubber bulb.

The treatment is very pleasant, and amazing results have been obtained, it is said. The ozone is driven directly into the lungs, where it is distributed throughout the body by the blood. In this way ozone inhalations not only have local effects but have excellent tonic and constitutional effects. For this reason ozone is so effective in cases of hay fever, which is the result not only of local irritations, but is also the result of lowered vitality.

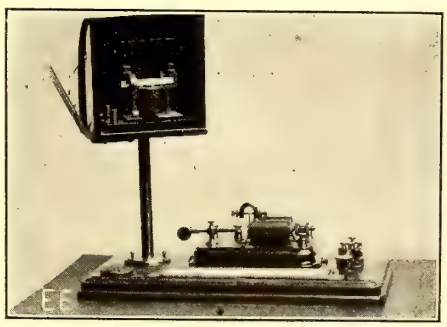
Ozone also acts as a powerful germicide and disinfectant, destroying the toxin products of bacteria through its power as an oxidizing agent. Quick relief and results are stated as obtainable in cases of hay fever, asthma, rhinitis, nasal catarrh, colds, bronchitis, et cetera.

Time is electrically flashed from powerful lamps on top of the Metropolitan tower in New York City which can be read 25 miles away.

MARCONI RADIOTELEPHONY.

Mr. Marconi states that the Italian navy is using his wireless telephone system as a part of its system of intership and intersquadron communication. In some instances, he said, communication had been established between ships as far apart as 100 miles. At the present time, he added, his efforts were being directed toward the perfection of the invention for moderate and not long-distance communication. He confirmed the report, that the wireless telephone would probably be on the market in the United States within the present year.

"Our new stations at Belmar and New Brunswick, N. J.," said Mr. Marconi, "are out of commission and will probably remain so until the end of the war, because of the taking over by the British Government of the two corresponding stations in Great Britain. The British stations are being used in long distance work, some of the messages being to points as far distant as Egypt. Our station at Marion, Mass., which was built to communicate with Norway, is also out of commission, owing to the fact that Great Britain will not permit the exportation of the equipment and material necessary to complete the Norwegian terminal."



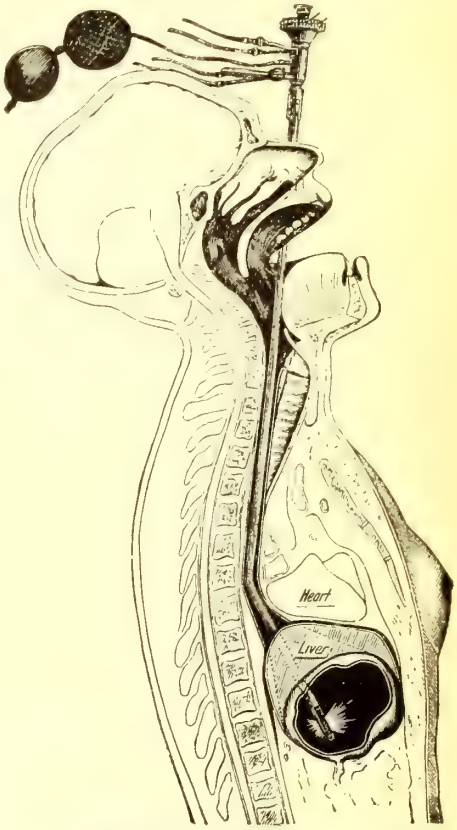
NAVAL WIRELESS IN JAMAICA.

Great Britain is erecting a powerful wireless station on the Blue Hills, near Kingston, Jamaica, according to latest reports. It is said the new station, which is 300 feet above the sea level, is intended to enable the Admiralty to send messages to the warships on the South Atlantic station.

Naval officers stationed at Kingston state that if such a plant had been in existence at the beginning of the war it would have prevented the defeat of Sir Christopher Cradock's fleet and enabled the warships on the coast to have picked up the Karlsruhe and the Dresden before they sank so many vessels.

TELEGRAPH SET THAT SIGNALED AROUND THE WORLD.

We present in the illustration shown a reproduction of the famous telegraph sounder, relay and key, as used a short time ago by Thomas A. Edison in sending the famous telegraph signal which circled the earth; repeating itself in the same office from which it had been sent



This Telegraph Set Signaled Through a 25,000 Mile Circuit.

out previously, but a few minutes before.

Of course, this was accomplished by relaying the message through several cable stations, in the globe-encircling journey. This apparatus is one of Uncle Sam's highly prized exhibits at Washington. Edison began his wonderful career as a telegraph operator, as have many of the present day leaders in industry and science.

ELECTRICAL ILLUMINATION OF THE STOMACH.

When the physician nowadays wants to find out what kind of a surface your stomach has he has other means at his disposal than the operating knife. Our illus-

How the Stomach Interior Can be Viewed by Using Small Electric Lamp and Suitable Jointed Tube.

tration shows how the perfected stomach lamp and periscope works. The metal tube of small calibre is passed through the patient's mouth and throat down into the stomach. By means of cleverly arranged reflecting mirrors in the tube the image is observed by the physician at the outer end of the tube. Rubber bulbs are shown attached for various requirements. Even surgical operations are performed through such tubes fitted with electric illumination.

MANY USES OF TUNGSTEN.

Tungsten is used principally as an alloy of high-speed steel—that is, steel used in making tools used in metal-turning lathes running at high speed—to which it imparts the property of holding temper at higher temperature than carbon steels will. The now well-known ductile tungsten is used for incandescent lamps, which are fast replacing carbon lamps. Recently greatly improved lamps, in which the wire is wound in helices and in which the globes are filled with nitrogen, have produced a close approach to white light. These lamps are furnished in candlepowers up to 2,000. Ductile tungsten is practically insoluble in all the common acids; its melting point is higher than that of any other metal, its tensile strength exceeds that of iron and nickel, it is paramagnetic, it can be drawn to smaller sizes than any other metal (0.0002 inch in diameter) and its specific gravity is 70 per cent. higher than that of lead.

If you are not a subscriber don't fail to read announcement on page 95.

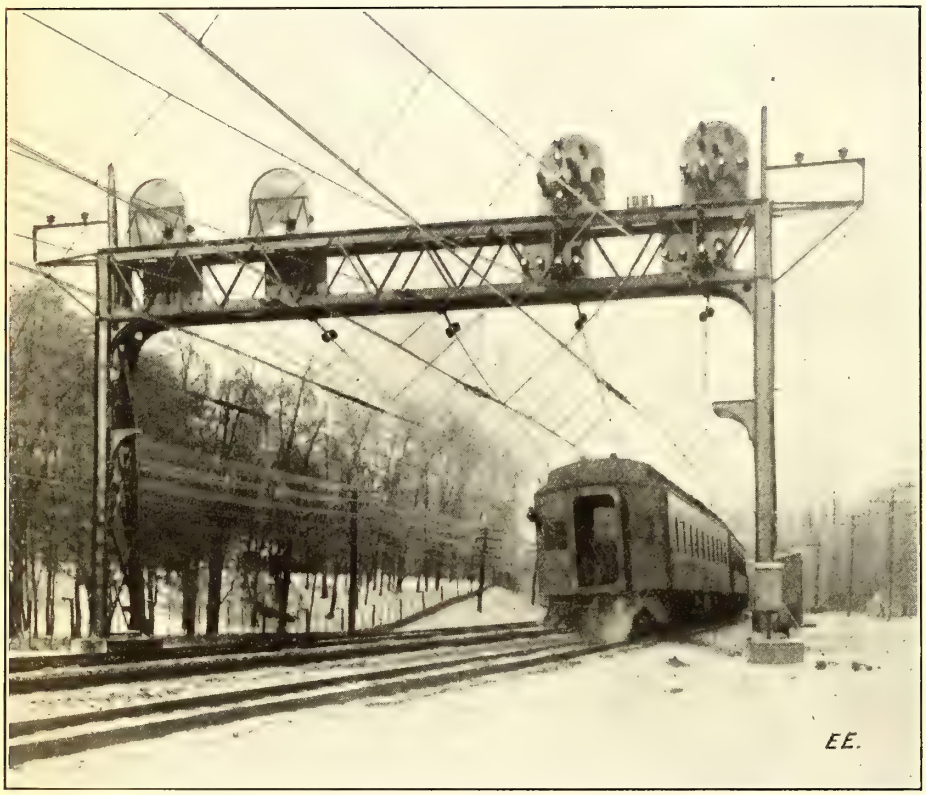
New Lamp Signals on Pennsylvania R. R.

AN entirely novel signal system, differing in all respects from any ever before used by any railroad, was recently placed in operation by the Pennsylvania Railroad from Overbrook to Bryn Mawr, Pa. This is a portion of the section of the main line between Broad Street Station, Philadelphia, and Paoli, Pa., now being electrified.

The new signals are especially designed to promote safety, efficiency and economy. All moving parts are eliminated from the signal apparatus. This not only reduces to a minimum the chance of getting out of order, but is also expected to lessen the cost of installation and maintenance.

The same signals will be used both day and night. Enginemen will therefore be guided by the same code every hour of the twenty-four, with corresponding reduction of the chance of error. Necessity for distinguishing between lights of different colors is banished by using only white lights.

The feature of the new signals is the substitution, for day and night use alike, of brilliant white electric lights, showing sharply against a black background in place of the moving arms of the semaphore, now used by day, and the colored lights used at night.



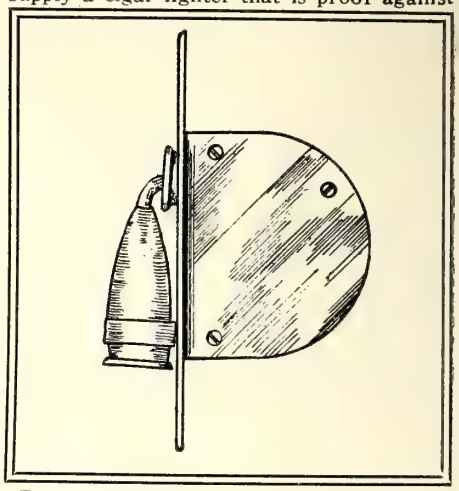
All positions of the semaphore arms—horizontal, diagonal and vertical—are duplicated in the new signals by the rows of electric lights. Each signal has a sufficient number of rows of lights to be the equivalent of two semaphore arms.

To make the lights clearly visible, even in the brightest sunlight, the voltage used in the daytime will be nearly quadruple that used at night. The lamps can easily be seen in the clearest sunshine for more than 4,000 feet.

So powerful are the lamps that when the full current is used at night it is possible to read large type by their light at a distance of 1,000 feet.

Each signal will protect a block of track 3,500 feet in length. A train passing a signal will automatically set it at "stop." When the train reaches the next block the first signal will change to "caution." Another position of lights will show when two full blocks are clear and a fourth position when three or more are unoccupied.

An engineman will always receive notice of a possible stop at least 7,000 feet in advance, and will receive two cautionary signals before approaching the "stop" signal.



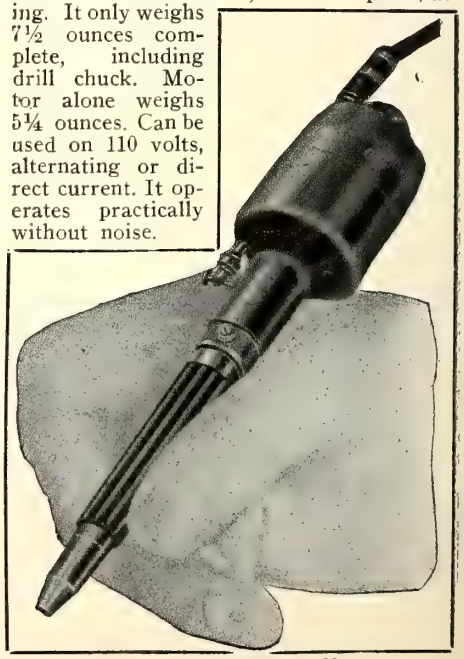
Latest Railroad Signal Employs Powerful Electric Bulbs Instead of Semaphore Arms. Lamps Can be Seen 4,000 Feet Even in Bright Sunshine.

INTERRUPTIONS IN RADIO TRANSMISSION FROM GERMANY.

The Nauen-Sayville and Hanover-Tuckerton transatlantic wireless systems, which have been transmitting the bulk of telegraph traffic between the United States and Germany since the cutting of the Emden cable, have for the past few weeks suffered severe service interruptions. Although the plants have been found to be sufficiently powerful to interchange messages, even by daylight, during the winter season, with the coming of warmer weather (and the accompanying increase of "static") communication has become impossible for a large part of each day. The Sayville transmitter is being enlarged so as to improve sending to Germany, but this will of course not aid reception in the United States. Many combinations of receiving apparatus are being tried both at Tuckerton and Sayville, in the hope of eliminating "static" interference to such a degree as to permit the German signals to be read. It is not known whether or not there will be any attempt to increase the sending power of the Nauen or Hanover station.

WINDPROOF ELECTRIC CIGAR LIGHTER.

Every smoker has experienced the difficulty of lighting a cigar or cigarette in a moving automobile or motor boat. A match is blown out instantly and even a pocket cigar lighter is extinguished by the wind. To supply a cigar lighter that is proof against the strongest wind and that works automatically is the object of a little electrical device that caused much interest at the recent Automobile Show.



Electric Cigar Lighter Which is Windproof.

It consists of a little knob hanging from a cord. This is attached to the most convenient part of the woodwork and takes up scarcely more room than an ordinary push button. When one wants a light he simply pulls out the knob and the end instantly glows with sufficient heat to light cigar or cigarette, the cord being of sufficient length to enable one to get a light without changing position. On releasing the lighter the cord is automatically rewound and the current automatically disconnected. The lighters are attached to the dynamo lighting circuit or batteries and are made for any voltage.

ELECTRIC MOTOR FITS THE HAND.

An extremely small electric motor is here shown, which is intended for dental drills and other work, such as perforating. It only weighs 7½ ounces complete, including drill chuck. Motor alone weighs 5¼ ounces. Can be used on 110 volts, alternating or direct current. It operates practically without noise.

Electric Motor Fits the Hand.

Many other uses for this extremely neat motor will suggest themselves to the reader.

How to Build a Photophone

By Homer Vanderbilt

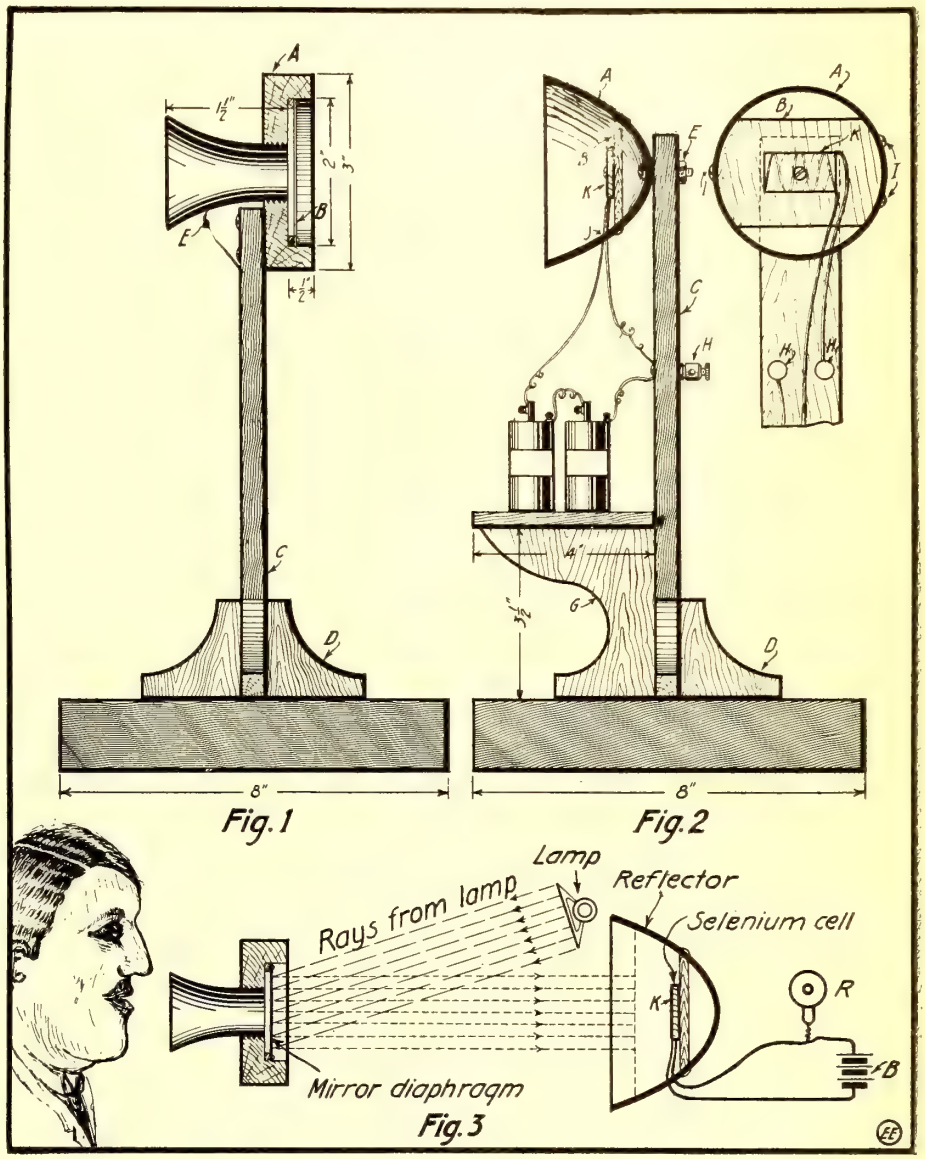
DR. ALEXANDER GRAHAM BELL, the inventor of the electric telephone, was the first to succeed in transmitting sound without the aid of any wire connection, although this method is not practical, but is interesting and valuable to many experimenters. His method of transmitting speech without wires will be described herewith, and details of constructing a simple photophone will be given.

This instrument will work very well for distances up to 900 feet. Dr. Ruhmer, the German scientist, has made photophones that have worked many miles. The photophone herein described was built by the writer, who has used it successfully for demonstration and experimental purposes.

Referring to the details, the transmitter is indicated at Fig. 1, and the circular transmitter head A is made from soft wood, turned out in a lathe, to the shape shown. Any wood turner will turn it out for a small sum. The diafram B is an ordinary tin one from a telephone receiver, and one side is nickel plated and highly polished; the reason for this will be explained later. The diafram is fastened to the head A by means of four small brass screws, or better, by a circular ring of wood. The supporter C is made from soft wood 10"x6"x1"; the base D measures 8"x7"x1½", and it is also made from the same material. Two small brackets are now fastened on each side of the supporter C, as shown. Next fasten the transmitter head on to the frame; this is done with two flat-head brass screws. The mouthpiece E is the ordinary telephone transmitter mouthpiece and can be readily obtained in any electrical supply house.

The receiving instruments are now to be considered. They consist of a parobolic reflector A, selenium cell K, battery B, telephone receiver R, and supporting frame for the parabolic reflector and selenium cell. The reflector is purchasable at small cost or can be made from a tin, copper or aluminum bowl. The bowl should not be larger than 12 inches in diameter. A small piece of wood B is made to support the cell K, and is held in place by means of three screws I, I, I, which are placed through three holes made in the bowl.

The supporting frame C and base D are made the same as for the transmitter, with the exception that C is one inch longer, as may be seen in drawing. A small wood shelf F is added, which can be 4"x8", etc. It is strengthened by means of a bracket G. The parabolic reflector is next mounted in place. It is supported by means of an 8-32 screw E.



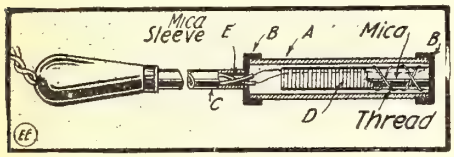
We now come to the most difficult part of the whole apparatus, and that is the selenium cell. This can be either purchased from any reliable concern or else made. A very easily constructed selenium cell was described in the August, 1914, *Electrical Experimenter,* and no further explanation is necessary here.

The selenium cell is placed on the plate B and fastened to it by two screws. Care should be taken not to tighten the screws too tight or the selenium will crack, which makes the cell worthless. The two terminals of the cell are brought through the hole J and one of the them is connected to one binding post H, while the other one is connected to two or three batteries, which are placed on the shelf F. The other terminal of the battery B is connected to the second binding post H¹, and a telephone receiver R is connected across these binding posts.

The apparatus is now completed and ready to receive a good coat of heavy orange shellac. To operate this photophone it is necessary to place both transmitter and receiver at right angles to each other and an ordinary carbide bicycle lamp is placed in such a manner that all the rays of light fall on the polished transmitting diafram B and are thus reflected onto the parabolic reflector A, Fig. 2. A good idea of how to arrange the apparatus is shown in Fig. 3. The writer advises the builder of this photophone to use it for short distances at first, until he familiarizes himself with the working parts of the apparatus. By using a larger source of light, such as an arc lamp, the distance may be considerably increased, of course.

For those who are not familiar with the principle upon which this instrument works, the writer has endeavored to show how this valuable and interesting apparatus operates. By referring to diagram 3, the receiver and battery are connected in series, the battery current is caused to vary and in this way causes the diafram of the receiver to vibrate according to the variation of current. Thus sound is transmitted exactly as spoken into the transmitter.

It is hoped that this short article on the photophone will interest many readers, who are interested in scientific research, as a great deal of experimental work may be performed on photophones. This apparatus may be advantageously used by Boy Scouts for signaling purposes, etc.



The Photophone Which Transmits Speech by Beam of Light.

Transcontinental telephone talk is made possible to a large extent by the De Forest audion amplifier.

AN ELECTRIC IMMERSION HEATER.

The first thing to be made for this useful form of heater is a one-inch pipe nipple A, 4 inches long, and two caps, B, B. In one of these caps drill a 5/16-inch hole and tap for ⅜-inch pipe. A ⅜-inch nipple C, about 3 inches long, is next inserted into this thread. Care should be taken to see

Simple Electric Immersion Heater.

that this case and nipple C is made watertight. This is facilitated by placing white lead on the threads.

The heating element is wound on a ⅞-inch porcelain tube D. Now wind 20 feet of No. 24 nichrome resistance wire on it, and each turn should be separated from its neighboring turn, so that they will not short-circuit each other. Lead about two feet of wire through the short nipple C. Splice on to these leads some lamp cord, or better yet, use asbestos insulated heater cord. Make the splice by twisting the wires together and insulate them with a winding of asbestos string. Try 110 volts across these leads. The element should heat up to a dull red, if not use less turns of wire. Get some thin sheets of mica and wrap them around the element, covering all exposed wire. Tie the mica on with some thread. This will hold it until placed in the case, when the thread will burn off, leaving the element insulated from the nipple by the mica. A mica sleeve E is next made and inserted in the nipple C. It is used to insulate the lead wires from the case. Turn up a short wooden handle of any desired shape and drill a hole through it. Lead the lamp cord through this hole and force the handle into the nipple. Test carefully to see that there are no *grounds* to the case. An attachment plug on the cord completes the heater. Be careful in using it, that it is always immersed, while the current is on, else it will soon burn out. The drawing shows the arrangements of the various parts.

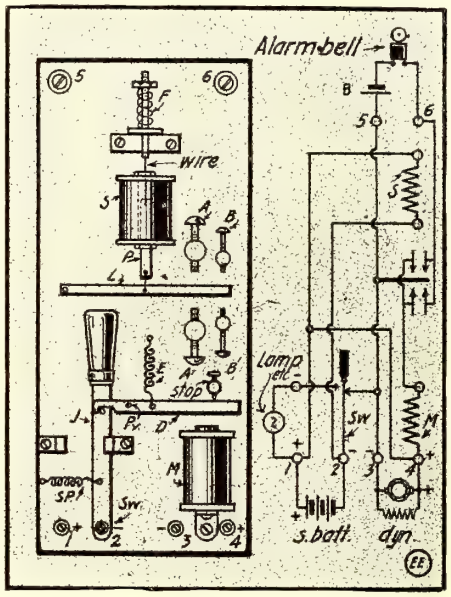
INVISIBLE INK RECIPES.

I am sending you some formulæ for invisible ink, for which I think the experimenter may find much use on various occasions.

Recipe No. 1.—Writing fluid: 1 drachm potassium iodide; enough water to make 1 ounce. Reagent: A strong solution of bichloride of mercury; apply with a brush and the writing will come out red.

Recipe No. 2.—Writing fluid: 1 drachm potassium ferrocyanide; enough water to make 1 ounce. Reagent: 1 drachm perchloride; enough water to make 1 ounce, or 50 per cent. solution of tincture of iron; apply with a brush and the writing will come out blue.

Recipe No. 3.—Writing fluid: 1 drachm cobalt chloride; enough water to make 1 ounce. Reagent: Heat, and the writing will be blue.



A small amount of acacia gum added to the writing fluids will improve the writing quality. I prefer the number one because it is easier to get, the paper is unstained and the writing can be erased by simply heating. I will be pleased to hear from any one who tries these formulæ.

Contributed by K. K. KNAELL.

AUTOMATIC BATTERY CHARGING BOARD.

The following is a description and illustration of a simple switchboard designed to call the operator's attention when the storage cells are fully charged or need charging. When the cells are charged to capacity the combined switch and circuit breaker shown on the lower half of the board cuts out the charging circuit, also rings a bell or similar alarm. When cells are discharged to a point consistent with safety the alarm again rings, indicating that the cells need charging.

Referring to the drawing, S is a solenoid wound with fine wire to a resistance of 120 ohms for a six-volt charging circuit. With higher voltages the ohmage of the solenoid must be increased proportionately. P is a soft iron plunger loosely suspended in the solenoid. At F is a spring and nut for adjusting the plunger, which moves *freely* in the solenoid. L is a brass bar, pivoted and connected to plunger P. A and A′ are adjustable contacts. B and B′ are also contacts similar to A and A′, but smaller. M is a strong electro-magnet wound with *large*

Clever Battery Charging Panel.

wire (No. 18 or No. 16) to resistance of *two* ohms. D is an iron armature lever shaped as shown, pivoted at PV, its end being a sort of trigger, engaging a pin attached to switch SW. SP is a rather strong spring to pull out switch blade, when released at J, over to switch contact on left.

The plunger P is made such a length as to enter less than half way into the brass solenoid tube. The plunger is drawn into the core in proportion to the rise in voltage, and released when the voltage decreases or falls. It is, in principle, a voltmeter.

Referring to wiring diagram, positive generator lead is connected to terminal 4; negative lead connects to 3. Positive storage-battery lead is connected to binding post 1 and the negative lead connects to binding post 2. Posts 5 and 6 connect to bell or other alarm in series with dry cell.

When wiring is finished and dynamo and storage cells connected to their binding posts, see that switch is in vertical position shown in sketch.

Commence charging until cells are fully charged. When this occurs, adjust contact A until it touches L. Do the same with B. This done, the magnet M attracts D, releasing switch, which is pulled to left-hand switch point by spring SP. Alarm will ring also. E is a small spring to hold the armature lever in horizontal position.

Now discharge battery to a point consistent with safety (about 1.78 volts per *cell*). Then adjust contacts A′ and B′ until bell rings. The board is now ready for steady work, requiring no attention other than throwing switch to right-hand switch point when charging.

If the dynamo is driven by an electric motor which is in series with a circuit breaker, by connecting the circuit-breaker magnet in series with the circuit-breaker magnet of the switchboard the dynamo will stop automatically when cells are fully charged.

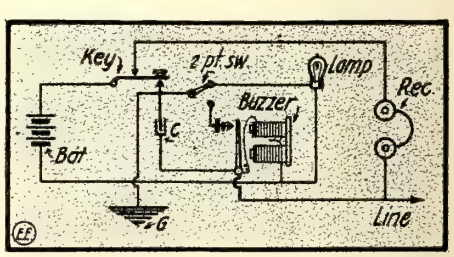
The switch parts, binding posts, contacts, also the solenoid and magnet, which are wound to order, can be supplied by any electrical house if you don't want to make them. Contributed by

CLARENCE W. GALLINGER.

STRONG MAGNETIC FIELDS.

An electro magnet constructed by Deslandres and Perot and described in a communication to the French Physical Society last year produced a magnetic field of 41,000 gausses in an air gap 2.1 millimeters long and 3 millimeters in diameter, with pole pieces of iron. The exciting current was 24 amperes in this case. The maximum field obtained was 51,500 gausses, utilizing 30,800 ampere turns.

With special pole pieces of cobalt steel a field of 50,500 gausses was produced in an air gap 1.7 millimeters long and 3 millimeters in diameter.



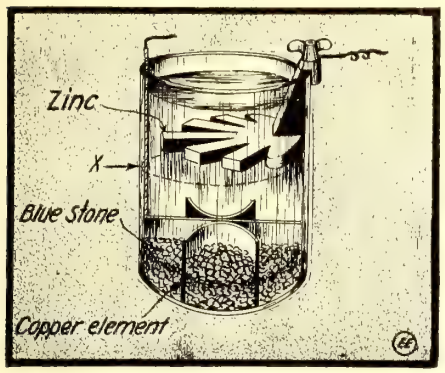
U. S. SIGNAL CORPS BUZZER TELEGRAPH.

The telegraph signaling system employed in the United States Signal Corps branch of the army is very ingenious and, as is generally known, will operate under very poor electrical conditions, as when the wire may be cut in one or more places, etc.

We show herewith diagram of connection as used in these field type, buzzer telegraph sets, and the signals are received at either station by means of head 'phones shown.

Closing the key at either instrument operates the buzzer, which creates a series of rapidly interrupted electrical impulses, having several times the voltage given by the battery owing to the high self-induction of the buzzer magnets.

This set is also arranged with a switch in some cases, so that at night the set may be utilized for flashing signals by means of a battery lamp, indicated on drawing. In this case, of course, no line wire or



U. S. Signal Corps Buzzer Telegraph.

ground connection is necessary and the signals are observed from at a distance by means of field glasses, etc., the short and long signals of the telegraphic code being produced by giving long and short flashes of light in the battery lamp.

It may be remarked that a small condenser is usually hooked across the buzzer contracts in order to reduce sparking.

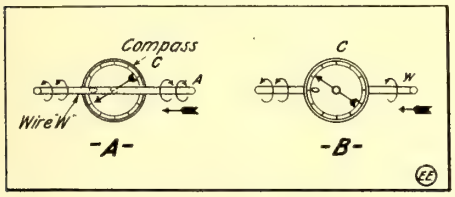
HOW TO CONSTRUCT A GRAVITY BATTERY.

To set up a gravity battery use about 3½ pounds of bluestone, or enough to cover the copper element 1 inch. Pour in water

Making a Gravity Battery.

sufficient to cover the zinc one-half (½) inch, short circuit for three hours and the battery is ready for use. If desired for use immediately do not short circuit, but add five or six ounces of "zinc sulphate."

Keep the dividing line X between the blue and white solutions about one-half inch below the bottom of the zinc. If too low, siphon off some of the white liquid and add the same amount of water, but do not agitate or mix the two solutions.



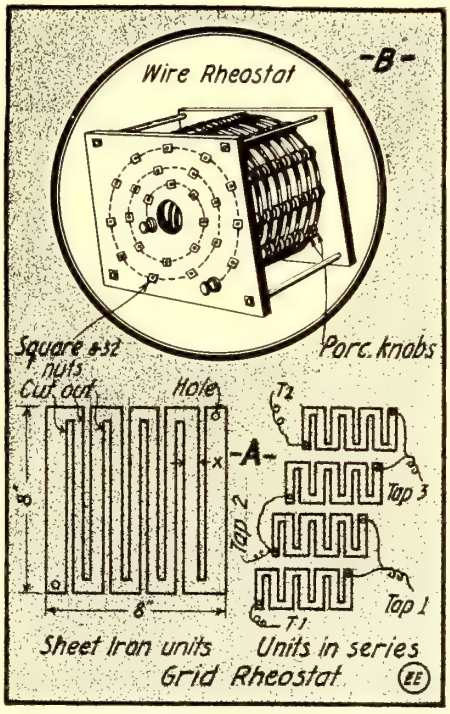
This type of battery will give about 0.9 of a volt, but only a fraction of an ampere. It is used for burglar alarm and closed circuit telegraph work very extensively.

Many amateur electricians and some professionals have undoubtedly had considerable trouble with gravity batteries. They follow directions carefully and then fail to get good results. The usual trouble is not with the battery itself, but with the circuit. A gravity battery is suitable only for a circuit which is normally closed. It is therefore undesirable for "electric bells," "induction coils" and all other open circuit apparatus requiring fairly strong current. The circuit should also have a high resistance. This makes it impractical for running fan motors, as the motor would have to be wound with fine wire. And it would then require a large number of batteries to give a sufficiently high voltage.

Contributed by W. JOHN GWINN.

DETERMINING DIRECTION OF AN ELECTRIC CURRENT.

If the current in a wire is flowing from south to north and a compass is placed under the conductor, the north end of the needle will be deflected to the west, as



How the Compass Acts When Placed Under and Above a Live Electrical Conductor.

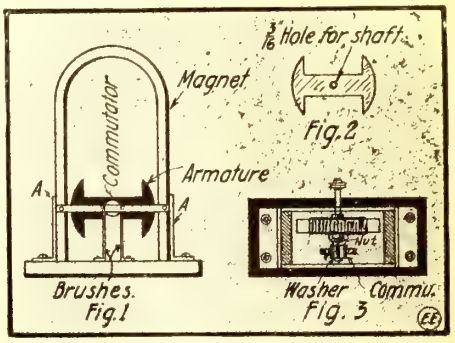
shown at A in sketch. If the compass is placed over the conductor, the north end of the needle will be deflected to the east, as shown at B. The compass needle should be placed parallel with the wire first. Even the current from a dry cell passing through a conductor to a bell, etc., will deflect the compass. This is the basic principle on which the galvanometer is built.

CONSTRUCTING RHEOSTATS.

Rheostats or resistance boxes are often required in electrical work, and a few types are illustrated here which the practical man will find of interest. At Fig. A is shown how ordinary iron sheet, or German silver sheeting, can be cut to resemble the grid resistances employed commercially for controlling motors, and so on.

The number of sheets used and the width of the strip X, as well as its thickness and length, are, of course, dependent upon the current required to be carried, as also the voltage drop to be effected. The physical properties of sheet metal are to be found in any handbook on electricity. It is easy to figure out the resistance required for a given load. It is equal to the volts drop required divided by the current in amperes to be used. Say, for instance, that 40 volts drop is wanted and a current of five amperes. Then the resistance of the whole rheostat must be five into 40 or eight ohms. The various grid plates can be connected in series or on parallel as desired. The total resistance of a series rheostat will be that of

Rheostat Construction and Details of Same.



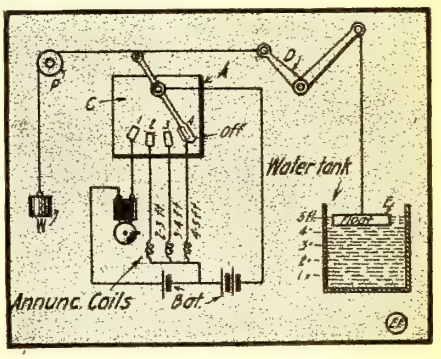
one grid multiplied by the number of grids. On parallel the total resistance will be that of one grid divided by the number of grids. The arrangement of grids in series is indicated.

A compact and cheap form of rheostat used for arc lamp ballast, etc., is the cylindrical type shown at Fig. B. Several layers of wire are used in a small space in this unique design. The turns are wound on small grooved porcelain knobs, placed on a series of 8-32-inch metal rods, threaded at both ends, and secured in place between two metal end discs by hexagon or square 8-32 nuts. Tap leads can be brought out, of course, as desired from any layers or parts of layers to switch points.

When a storage battery is only partially discharged it requires only a partial charge. Charging a battery that is already full is not only a waste of current, but it is injurious to the battery, and care should be taken to cut off the current as soon as the maximum charge is attained.

HOW TO MAKE A SMALL ELECTRIC MOTOR.

A small electric motor can be readily made from odd parts by any experimenter. The magnetic field is supplied by a permanent magnet of the horse shoe type, as perceived. The armature consists of eight or



Electric Motor Which is Easily Made.

10 pieces of soft iron, cut as shown in Fig. 2, and made from No. 27 soft sheet iron, or tin will do. The armature sheets are kept in place on the shaft by two nuts which are tightened up firmly on either side or they may be soldered in place. The bearings are made of heavy sheet brass with a 3/16-inch hole on each end and one in the center, to take the shaft. Next arrange bearing support A A, of brass.

The stand consists of four, or better, one piece of brass, screwed to the base on each side of the magnet. A 3/16-inch shaft threaded at the center carries the commutator and armature. The commutator is made from a wooden cylinder ½ inch in diameter and ½ inch long, and it is secured on the shaft by forced fit. The wooden cylinder is now covered with some heavy tin foil, which must be securely glued on and afterwards cut into two pieces, to make the two segments as shown in Fig. 3. Now wind the armature core with seven or eight layers of No. 24 insulated magnet wire and carefully fasten the ends to the two commutator segments by small nails or screws. Two short pieces of sheet brass for brushes are next bent, as shown in Fig. 1, and are secured to the base by means of two brass screws. These strips act as brushes and should touch the commutator very lightly, but at the same time making good contact with the commutator.

A WATER-LEVEL SAFETY ALARM.

A very simple water-level safety alarm can be readily rigged up by following the instructions and drawing given herewith.

Simple Water-Level Alarm.

At first construct a trip switch A shown in drawing, which consists of brass contacts 1, 2, 3, 4, and a lever B mounted on a suitable base C. Next construct the lever arm A with its float E. After these parts are completed mount them on a wooden

(*Continued on page* 102.)

WRINKLES—RECIPES—FORMULAS

Edited by S. GERNSBACK

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA No. 11.
Photographic Baths.
(DEVELOPERS).

Eikonogen Developers.—No. 1. 20 oz. *Distilled Water,* 2 oz. of *Sulphite of Soda* (cryst.), ½ oz. of *Eikonogen Crystal.* No. 2. 20 oz. *Distilled Water,* ¾ oz. *Carbonate of Potash.* Mix No. 1 and 2 in equal parts, and to each ounce add 2 to 4 drops 10 per cent. solution *Bromide of Sodium.*

Hydrochinon Developer.—No. 1. 10 oz. *Distilled Water,* 2 oz. of *Sulphite of Sodium* in cryst. chem. pure, 1 oz of *Hydrochinon.* Dissolve and keep in a yellow bottle. No. 2. 10 oz. of *Distilled Water,* 2 oz. of *Carbonate of Potash,* 1 oz. of *Carbonate of Soda.* Mix 2 drm. of No. 1 and 1½ drm. of No. 2, then add 3 oz. of *Water* (dist.).

Combined Hydrochinon and Eikonogen Developers.—No. 1. 60 parts of *Sulphite of soda* (cryst.), 40 parts of *Crystal Soda,* 1,000 parts of *Distilled Water.* After solution filter. No. 2. 50 parts of *Eikonogen,* 50 parts of *Hydrochinon.* Place together in a mortar, grind down to fine powder and keep dry in well stoppered glass bottle. For use take one part of No. 2 and dissolve it in 100 parts of No. 1. This developer is one of the best known; it possesses all the advantages of the other developers, without their disadvantages.

Iron Developer.—No. 1. 120 gr. of *Citric Acid,* 88 gr. of *Carbonate of Ammonia,* 1 oz. of *Distilled Water.* No. 2. 140 gr. of *Sulphate of Iron,* 1 drop of *Sulphuric Acid,* 1 oz. of *Distilled Water.* To 3 parts of No. 1 add 1 part of No. 2.

Ferrous Citro-Oxalate Developer.—No. 1. 1 oz. of *Neutral Oxalate of Potash,* 2½ oz. of *Bromide of Potassium,* 5 oz. of *Hot Distilled Water.* No. 2. 2 drm. of pure *Proto-Sulphate of Iron,* 2 oz. of hot *Distilled Water.* Mix together 2 parts of No. 1 and 1 part of No. 2.

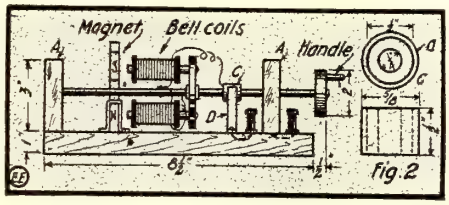
Pyro Developer.—Dissolve and keep in tight fitting stoppered bottles. No. 1. 50 grn. of *Pyrogallic Acid,* 150 gr. of *Sodium Sulphite,* 10 gr. of *Citric Acid,* 1 oz. of *Distilled Water.* No. 2. 50 gr. of *Potassium Bromide,* 1 oz. of *Water.* No. 3. 2 drm. of *Ammonia* (0.880), 2¼ oz. of *Distilled Water.* Take 1 part of each and mix.

Tintypes Developer.—1 oz. of *Distilled Water,* 14 grn. of *Sulphate Iron,* 10 gr. of *Saltpeter,* 30 min. of *Acetic Acid,* 2 min. of *Nitric Acid.* S. G.

NEW INVENTIONS IN PHOTO-PLAYS.

(*Continued from page* 86.)

for many years, which consists of making the suspected thief or criminal hold some rice in his mouth. The suspected persons are lined up in court and sentence pronounced; afterwards the rice from each one of their mouths is removed and examined by experts. The one from whose mouth the rice shows no moisture is invariably the guilty one; as it is claimed that although their faces may not show any change of emotion when they are guilty there is an inward muscular and nerve action taking place which causes the saliva to be checked and thus the mouth remains dry.



AN ELECTRIC TICKLER.

A very simple but amusing little machine can be made by anyone who is familiar with the handling of common tools. The following material will be necessary in order to construct this little alternating-current dynamo. Two electro-magnets, taken from an old electric bell; a 5-inch horseshoe steel magnet; two brass standards, A A, 3x½x½ inch; 4 inches of ¼-inch round brass rod; ½ inch of ½-inch diameter round rubber rod; also a wooden base 8½x5x1 inch, two binding posts and brass wood screws.

At first mount the steel magnet in an upright position by means of a brass strip as shown. Next construct the armature, which consists of two electro-magnets mounted on ¼-inch brass shaft. Upon this shaft mount a collector ring C, which is made from hard-rubber rod, shown in Fig. 2. A brass cylinder (a) is then put on the rubber rod.

The shaft is supported by means of two brass standards as shown. One terminal of the electro-magnets is soldered to the shaft, while the other terminal is soldered to the ring C. A brass spring D is next placed on the base so that it will touch the ring C as shown. A small handle and disc are next made and placed upon the shaft.

Connections are made from one standard and from the brass spring D to the two binding posts. By turning the crank handle and holding two conductors, which are

Two Rotating Magnet Coils Make this Electrical Tickler or Shocker.

connected to standard and spring, a shock is obtained. By turning the electro-magnets faster or slower the strength of the shock is varied in proportion. This is the principle of large dynamos, and the first electro-medical machines made by Kidder and others were similarly designed. A couple of tin handles about ¾x4 inches serve very well.

OUR NEXT NUMBER

Will have as a special supplement a large picture of

MARCONI

suitable for framing. This will make an ideal portrait for your den or home. There will also be many new features in the August issue. Be sure to order your copy now.

A WATER-LEVEL ALARM.

(*Continued from page* 101.)

base. The pulley P is placed on left-hand side of the base as shown. An electric annunciator is connected to three of the plugs of the switch A, and the last contact is made with a bell. The connections are shown in the drawing. Now if the amount of water decreases the float will sink, and as soon as the level is below the 4-foot line the switch arm will make contact with the next contact piece and the annunciator will show its 3-4 feet drop. Next will come 2-3 feet, and then, when the float has sunk below the 2-foot line, the arm will come upon the last contact and the alarm bell will ring, notifying the engineer that the tank is nearly empty.

BOOK REVIEW.

"Elementary Electricity and Magnetism." By William S. Franklin and Barry MacNutt, 174 pages, 153 illustrations. Cloth, 7½x5 inches. Leather back. The Macmillan Co., New York. Price, $1.25.

This book is rather refreshing in a way, considering the method used in explaining the elements of electrical units, circuits, magnetism, etc. Practical aspects of the action taking place in electrical and magnetic circuits are explained in a very logical way with the aid of special diagrams. It is a good book for students of all classes and really gives a thorough understanding of the electro-physical action occurring. The heating and chemical effect of electricity is explained with simple formulæ, so that anyone can understand them.

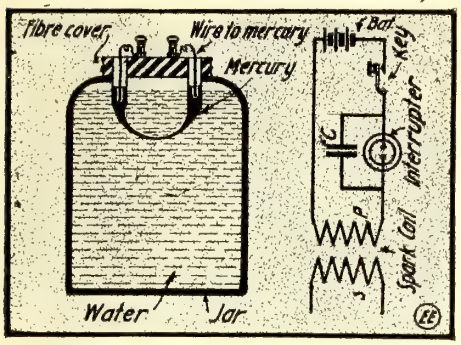
A particularly interesting section deals in an excellent and new manner with the "electric charge and the condenser." This section explains such vitally interesting things also as "spark discharge and corona," "electrical precipitation of smoke and dust," etc.

"A School Electricity." By C. J. L. Wagstaff, M.A. 250 pages and 136 illustrations. Green cloth, 9x6 inches. G. P. Putnam's Sons, New York. Price, $1.50.

Mr. Wagstaff has presented his treatment of electricity and magnetism in a rather new way, so to speak. The magnetic field of force is thoroughly covered and some new curves and figures of the magnetic flux field around different magnets and circuits are presented. This is a good book for the student and will undoubtedly give him a very keen perception of the laws of magnetism and electric currents.

Each chapter has a number of questions at the end of same, and numerous practical experiments are described. All teachers of electrical subjects would do well to look over this work. About a dozen fine plates appear at the end, showing clearly how the magnetic flux appears in the field of various magnet poles.

"The Boy Electrician." By Alfred Powell Morgan. 394 pages, 324 illustrations. Cloth. 8vo. Price, $2.00. The Lothrop, Lee & Shepard Co., Boston, Mass.



A new and extremely practical book for the boy and young man is this latest work of nearly 400 pages from the pen of Mr. Morgan. Every kind of intrument imaginable is described in attractive style, with excellent working drawings to guide the builder of same. A good feature is that which incorporates half-tone or photographic views of the various completed apparatus so that the reader will be sure to understand just how each instrument looks when finished. Wireless apparatus as well as high-frequency coils for demonstration, etc., are clearly described.

BIRD CROSSES WIRES.

Recently mention was made of a cross on a line in California caused by a snake, says *Telegraph and Telephone Age.* Now J. L. Henritzy, superintendent of telegraph of the Colorado & Southern Railway, Denver, Col., writes that one of his linemen cleared a cross by removing a Chinese pheasant, whose neck was in the twist of two wires. As the bird had not been dead over an hour, it made a toothsome morsel for the table, besides supplying beautiful long tail plumes.

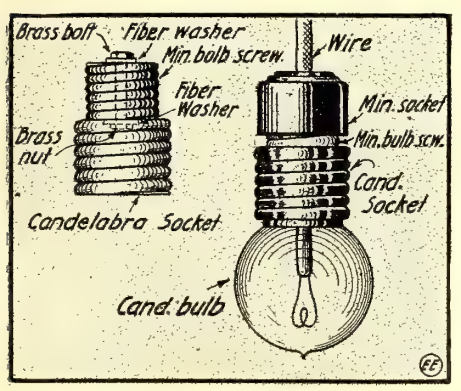
UNIQUE SPARK COIL INTERRUPTER.

Here is a description of a really practical interrupter which gives perfect satisfaction on coils up to 3-inch spark. With

Unique Mercury Interrupter for Small Coils.

this interrupter sticking contacts, etc., are unknown.

To construct the apparatus, secure a two-pint "Mason" fruit jar and cut from fiber a cover to fit. Bend and draw out a glass tube as shown, making the hole in the middle of the bend almost as small as that in a thermometer tube. Bore two holes through the fiber cover and fit the arms of the glass tube tightly into them. Mount two binding posts on the fiber top and connect short pieces of No. 14 copper wire to them as shown.



To operate, fill the jar with water to the level shown, and the bent glass tube with mercury to about the same level. Experiment will show the exact height to which the tube must be filled. Now connect the interrupter in series with the spark-coil primary, key and battery, having previously removed the hammer interrupter or bridged it across with wire. As soon as the current is switched on a bright green spark will appear in the tube.

The water in the jar serves to carry off the heat generated. The interruptions are of a higher frequency than those obtained with a vibrator and are steadier. This interrupter was invented by Mr. H. Gernsback in 1904. Contributed by

JAMES L. GREEN.

MAKING CANDELABRA BASE LAMPS FIT MINIATURE SOCKETS.

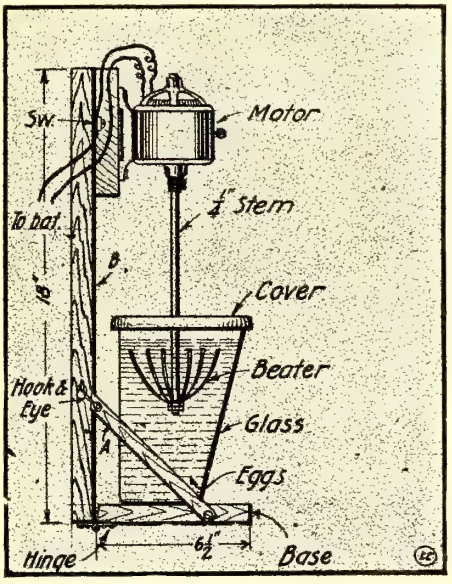
Secure an old burned-out miniature bulb; break the glass and scrape the plaster of paris out. Take the fiber washer out

How to Use Candelabra Base Lamps in Miniature Sockets.

and put it on the other side; then put the bolt through. Then place the candelabra socket on and put a fiber washer in it. Clamp the nut and screw up tight. If when screwed in a miniature base it refuses to work, melt a drop of solder and put it on the head of the bolt, but be sure the bolt is well insulated from the brass socket. Then screw it on a miniature socket and put in your candelabra bulb. Contributed by ALBERT PETTY.

BEDSPRING AERIALS.

I find that when using small radio receiving sets that they work better by using a steel woven wire mesh bedspring for an aerial than an indoor aerial consisting of five strands of copper wire, 1 foot apart, having a total length of about 60 feet.



Contributed by E. J. BACHMANN.

The trans-Atlantic wireless stations in Germany have been heard clearly at the University of North Dakota radio station, a distance of 4,300 miles.

ELECTRIC EGG BEATER.

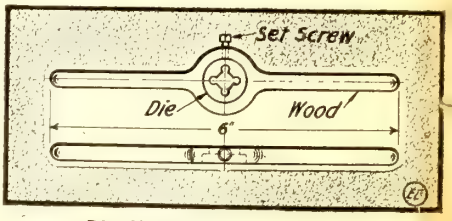
Secure a base 6½ inches long and hinge it onto an 18-inch upright piece as shown. Fasten a block 2 inches thick at top and to this fasten an electric motor. Fasten on the shaft a ¼-inch brass stem and then solder some light strips of tin to the end and bend as shown.

The base has a hinge so it can be low-

Egg Beater Driven by Small Motor.

ered to put glass of eggs on. A is a brace which can be hooked onto B. The motor may be arranged to slide up, so as to remove beater head from eggs or phosphate container without hinging upright. Contributed by CLARENCE LINDGREN.

A TIN-FOIL ADHESIVE FOR CONDENSERS.



A very good way to secure tinfoil on condenser plates, and one which will not cause blistering, which is so disastrous to condensers, is as follows: Place the plates to be coated in a moderately warm oven and heat them for about 5 minutes. Then remove them and rub the surface with beeswax. Place the tinfoil over the wax and smooth down. It is advisable to place a lug of thin copper ribbon on the plate under the tinfoil before the tinfoil is put on. The corners should be painted with beeswax after the tinfoil has been placed on the glass. It is best to round the corners of the tinfoil sheet. Beeswax is far superior to shellac for this purpose.

WALTER FRANSEEN.

WOODEN DIE HOLDER.

I am sending you a drawing of a home-made wooden die holder which I used because I did not have the right-sized holder for a small die. Bore hole half way through the wood handle as shown, so that die will fit very snugly. Bore a small hole for the threaded rod to go through. Put

Die Holder Made of Wood.

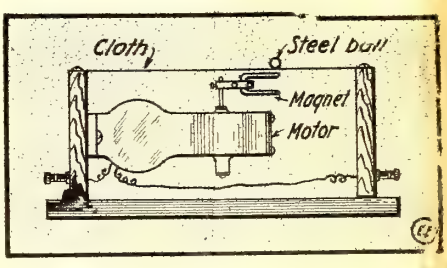
die in larger hole and thread a screw in the notch on the edge of the die as usual. This holder will do real serviceable work.

Submitted by

NELSON RULAND.

HOW TO MAKE SOLDERLESS CONNECTIONS.

Perhaps some readers find trouble in making a good wire connection when solder is unavailable. I think they will find the following very efficient, especially with aluminum wire.



First, scrape about eight inches of the wire to be connected. Be sure all corrosion, dirt, or grease is scraped off thoroughly. Then twist the wires together very tightly. A piece of tinfoil about an inch wide is lapped over the connection twist. The tinfoil should be lapped as tightly as possible without tearing, then pressed together with the fingers. After this lap one or two layers of tape over the tinfoil, so no corrosion or rain can get to the tinfoil. The tape is pulled very tight so as to insure a good connection between the tinfoil and the wire. It is well to paint it with asphaltum.

It should be understood that this little scheme should only be used when solder is not handy.

Contributed by D. K. WALKER.

A MAGNETIC WINDOW ATTRACTOR.

Make a small box 8x4x4 inches. Two inches from one end put a block 3x2 inches. Upon this place a small motor so that the armature does not project over the top. To the armature fasten a small stick with a horseshoe magnet attached to one end of it. Put a very thin piece of cloth over the

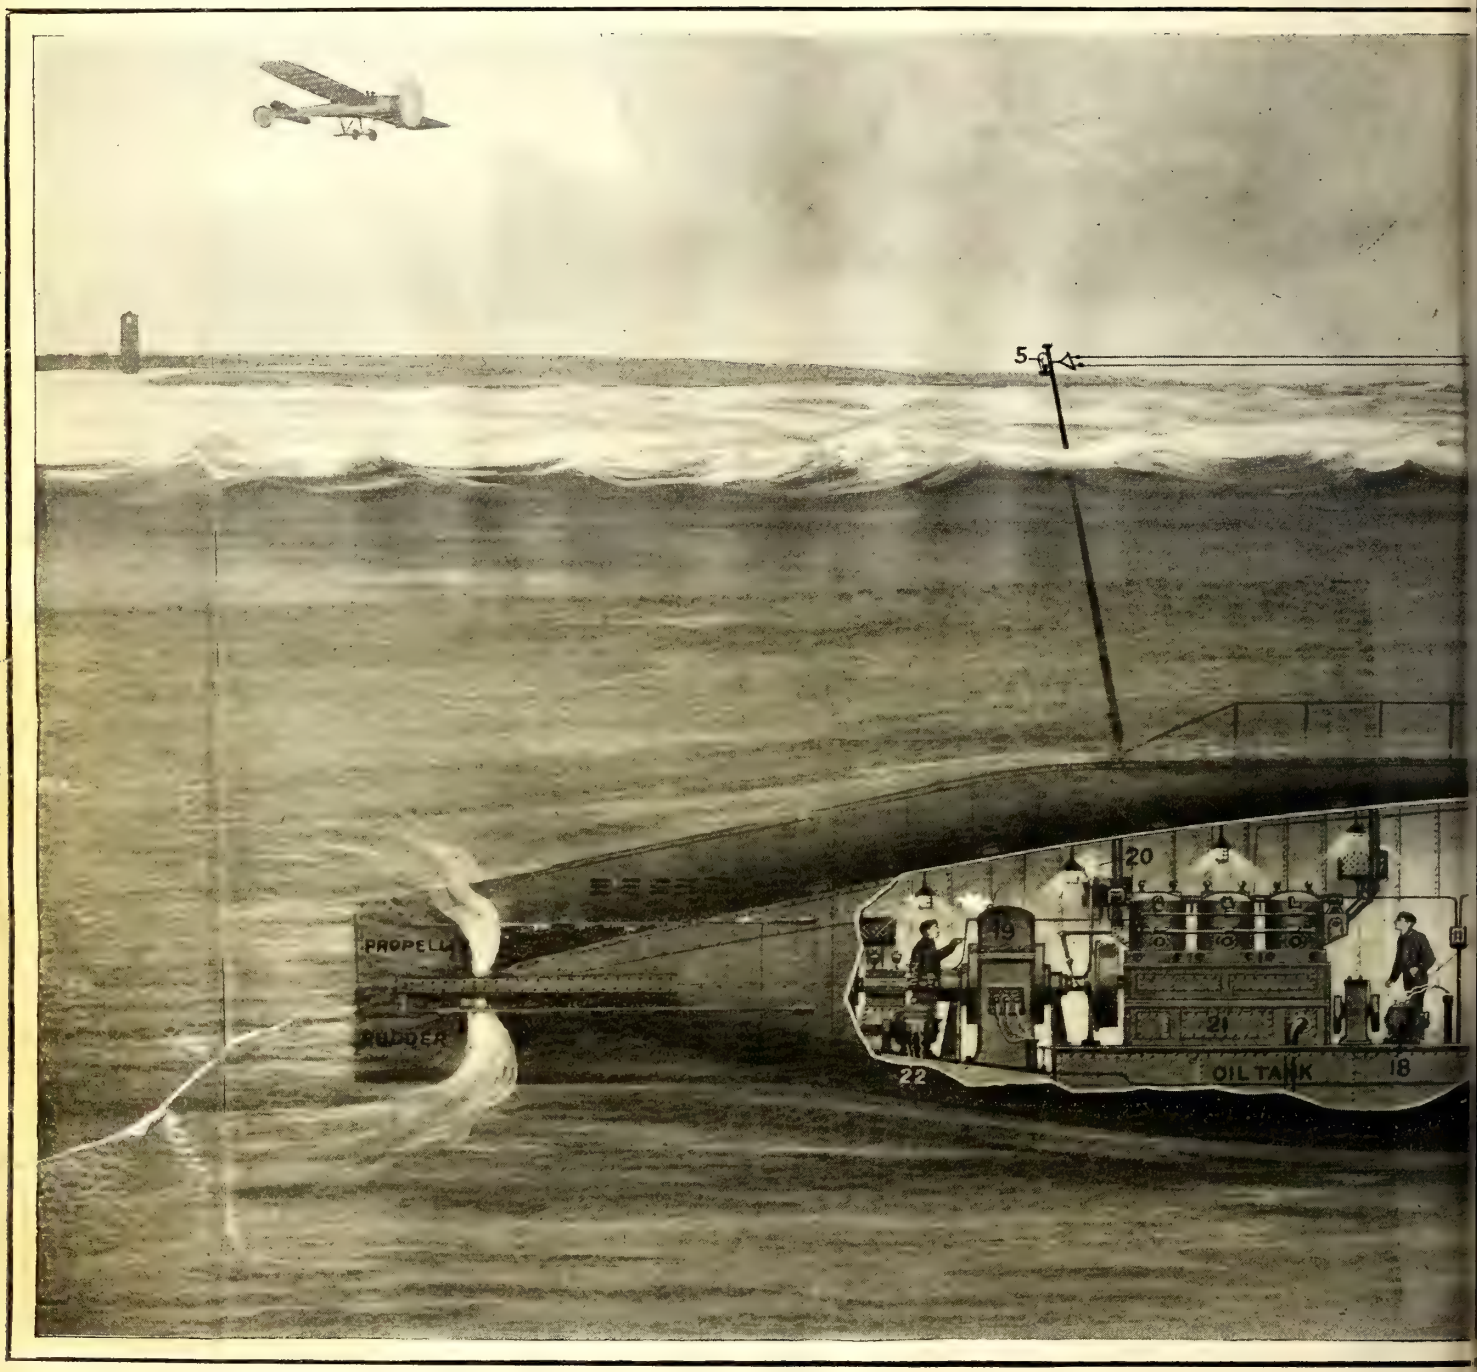
Show Window Novelty Easily Made.

top so the inside of the box does not show. Arrange it so that the magnet nearly touches the cloth. On top put a steel ball bearing. To each end attach a binding post. the ball will follow the rotating magnet. A glass mirror top on the box is best, but requires a stronger magnet than when cloth is used. Contributed by

EARL PRATT.

ELECTRICITY, THE POWER

By



THE submarines have proven, even thus far in the great European war, that they are indeed of extremely valuable service and that even though they are much cheaper to construct than the wonderful "dreadnoughts" costing ten to twelve million dollars apiece, they can on the surface of the water they invariably make use, of course, of gasoline or internal combustion engines, using crude oil such as the Diesel type.

For this kind of cruising some of the latest United States submarines make use of a 900-h.p. Diesel oil engine, which makes it possible for these boats to attain a speed of 14 knots, and sufficient oil fuel is usually carried, enabling them to make a cruise of 5,500 miles.

Several of the submarines of this type, which took part in the recent Naval Demonstration and Review in New York Harbor, made a 1,500-mile run up the coast from Florida without incident, under their own power. Thus, it is seen that Uncle Sam's underwater boats are on par with those of the German and other navies.

At present there are about 35 submersibles in actual commission, and the total number, including those being built and those undergoing repairs, is 55.

Electricity is the wonderful form of energy which enables these craft to be propelled through the water submerged for distances of 100 and more nautical miles at a maximum underwater speed of from 10½ to 11 knots. Powerful electric motors drive the propeller blades for this under-

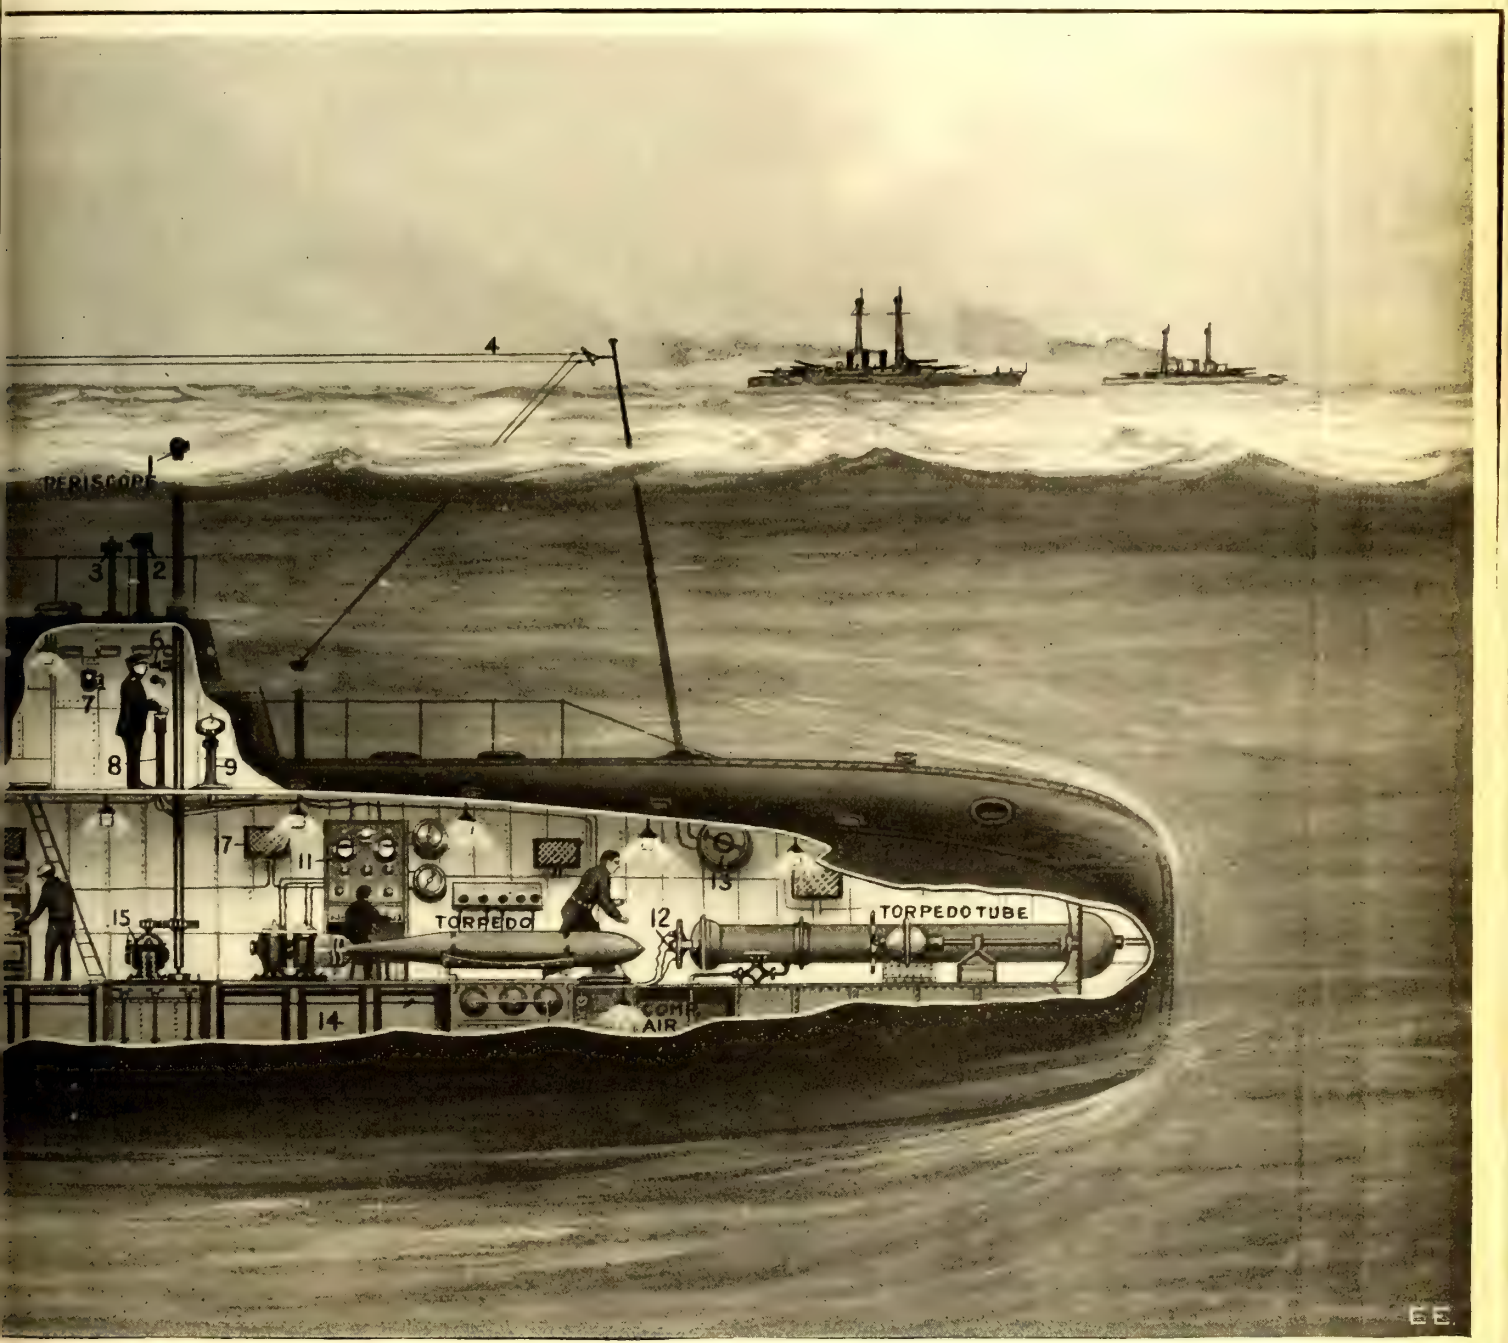
very easily and shortly, under certain conditions, dispatch these great fighting-ships to the bottom of the seas in a few minutes' time.

Probably more than is generally realized, electricity is really the backbone of these wonderful underwater engines of destruction. When these submarine boats travel

IND THE SUBMARINE BOAT



Secor

water propulsion, the motors developing 650 h.p. at the above full-speed rating in knots. These motors and all of the other electrical appliances on board the submarine obtain their energy from storage batteries, which, of course, have to be quite large. Practically all storage batteries including Thomas A. Edison, are and have been working for a considerable time toward perfecting a storage battery for this class of work which would not give forth poisonous fumes, etc.

Mr. Edison's latest submarine storage battery promises to fulfil these requirements in very good shape, besides having several other features which can be turned to good account in the submarine installation, such as revitalizing the air, etc.

The illustration herewith given shows a number of the more important uses to which the electric current is put on board the submarine. Of course, all the larger and latest type boats of this character carry a high-grade wireless set to be used with an antenna supported between two steel masts, as will be seen. It is claimed that the Germans have obtained much of their inside or secret information from spies, etc., by means of wireless messages sent out from secret or hidden wireless stations on land in England, and which messages have been picked up by some of the German submarines lying off the coast a few miles. These submarines can then of course, cruise away until they get within touch of some wireless communication

ELECTRICITY, THE POWER BEHIND THE SUBMARINE BOAT

By H[illegible] Secor

THE submarines have proven, even thus far in the great European war, that they are indeed of extremely valuable service and that even though they are much cheaper to construct than the wonderful "dreadnoughts" costing ten to twelve million dollars apiece, they can on the surface of the water they invariably make use, of course, of gasoline or internal combustion engines, using crude oil such as the Diesel type.

For this kind of cruising some of the latest United States submarines make use of a 900-h.p. Diesel oil engine, which from Florida without incident, under their own power. Thus, it is seen that Uncle Sam's underwater boats are on par with those of the German and other navies.

At present there are about 35 submersibles in actual commission, and the total number, including those being built and

very easily and shortly, under certain conditions, dispatch these great fighting-ships to the bottom of the seas in a few minutes' time.

Probably more than is generally realized, electricity is really the backbone of these wonderful underwater engines of destruction. When these submarine boats travel makes it possible for these boats to attain a speed of 14 knots, and sufficient oil fuel is usually carried, enabling them to make a cruise of 5,500 miles.

Several of the submarines of this type, which took part in the recent Naval Demonstration and Review in New York Harbor, made a 1,500-mile run up the coast those undergoing repairs, is 55.

Electricity is the wonderful form of energy which enables these craft to be propelled through the water submerged for distances of 100 and more nautical miles at a maximum underwater speed of from 10½ to 11 knots. Powerful electric motors drive the propeller blades for this underwater propulsion, the motors developing 650 h.p. at the above full-speed rating in knots. These motors and all of the other electrical appliances on board the submarine obtain their energy from storage batteries, which, of course, have to be quite large. Practically all storage batteries used for these installations are of the usual lead type.

These batteries make use of sulphuric acid, of course, and hence they give off very poisonous fumes, which often endanger the health or even lives of the crew when the boat is submerged for a number of hours. Therefore several inventors, including Thomas A. Edison, are and have been working for a considerable time toward perfecting a storage battery for this class of work which would not give forth poisonous fumes, etc.

Mr. Edison's latest submarine storage battery promises to fulfil these requirements in very good shape, besides having several other features which can be turned to good account in the submarine installation, such as revitalizing the air, etc.

The illustration herewith given shows a number of the more important uses to which the electric current is put on board the submarine. Of course, all the larger and latest type boats of this character carry a high-grade wireless set to be used with an antenna supported between two steel masts, as will be seen. WIRELESS DEPARTMENT

New Arc Radio Set For Ships

A NEW arc type wireless outfit was recently developed by the DeForest Radio Telegraph & Telephone Co. for use on ships. The photograph shows the complete outfit as it is installed on the steamship *Wm. Chapman.*

The transmitting set consists of an arc of special design, shown at center of switchboard in photograph. This arc contains two gaps in series, operated by 600

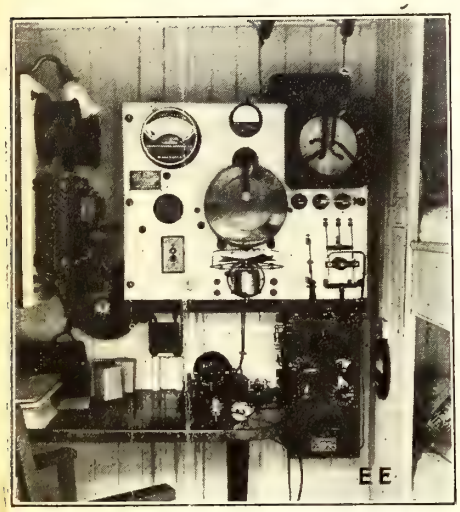

Fig. 2. Showing New Arc Radio Generator Installed on the Steamship "Wm. Chapman."

volts direct current, supplied by a motor-generator set.

The electrodes, P in the diagram, Fig. 1, consist of an alloy of platinum which has a very high melting point. The large discs O act as heat radiators, and the gap is also cooled by a fan below it, as shown. The gap between the electrodes is regulated by a thumbscrew Q placed in front of the arc. Fig. 1 shows the exact construction of this arc. The secondary circuit of the arc consists of a condenser behind the switchboard, a helix mounted on the right-hand front corner of the switchboard, hot wire radiation ammeter and a control switch for changing from 600 meters to 300 meters wave length. An aerial throw-over switch is also mounted at the extreme right. The primary circuit includes an ammeter mounted on the extreme left of the switchboard and connected in series with a choke coil, etc., as the diagram indicates.

The most interesting part of this arc is in starting it. When starting every arc it is first necessary to close both electrodes together and after separating them an arc is then formed, but with this radio arc it is only necessary to close a switch, which short-circuits the generator for a moment through a powerful choke or impedance coil and suddenly opening the switch. As soon as the switch is opened an arc is formed at this contact of the switch, which is extinguished by blowing it. The arc at the special gap electrodes is immediately formed. The distance between the gaps is about one-eighth of an inch long.

When in operation this arc produces undamped oscillations which cannot be received with the ordinary detector on ships, so a specially designed rotary commutator is employed for changing these undamped oscillations into ordinary spark oscillations of lower frequency. This device is called a "chopper" and is seen on top of the table. With this chopper the operator can send to ships and also to land stations having the Poulsen tikker receiving outfits just by cutting out the chopper, which is done by means of a double-pole single-throw switch next to the motor when the arc's undamped waves are sent out.

The motor-generator is located in the engine room and is operated by a hand control switch and an automatic solenoid switch. The panel on the extreme left of the room shows the generator board with all the necessary instruments, including ammeter, etc.

This particular outfit is rated at 2 K. W. and a maximum aerial reading of 5 amperes is obtained. The aerial consists of six wires 40 feet long. The receiving outfit consists of the latest type Audion detector and is seen on the right.

Simplicity is the principal feature of this well-built set, which is a new departure in American-made wireless apparatus.

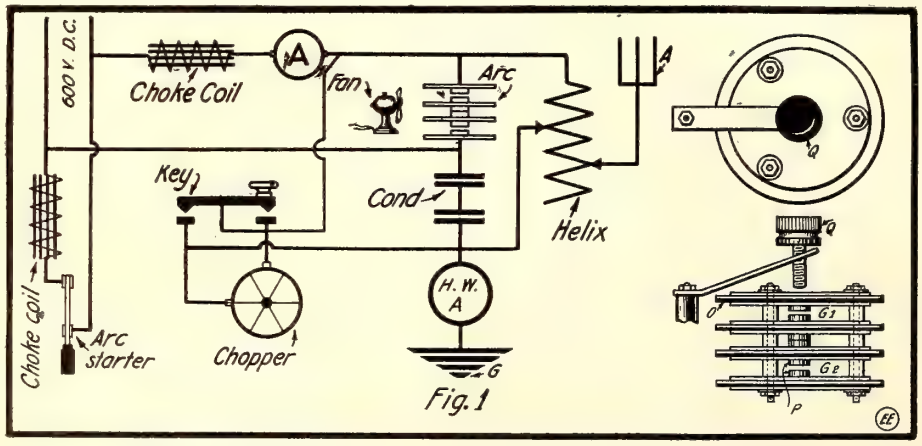

Fig. 1. Diagram of the New DeForest Arc Type Wireless Transmitter.

THE KEYSTONE WIRELESS ASSOCIATION.

The Keystone Wireless Association was organized in February, 1915, with six members, B. Bimson, William Boyle, L. Clancy, H. Forker, S. Hancox and W. Rusling.

The members meet in the basement of Brother Bimson's house every Saturday night at 8 o'clock to practise the code and qualify for a license, or anything else that they wish to do. We have a small library with wireless books such as *The Electrical Experimenter.*

We would like to have any young men interested in wireless and between the ages of 17 and 25, inclusive, to join. Anyone desiring information will receive same by writing or calling on S. Hancox, 685 Lexington avenue, Brooklyn, N. Y., any evening.

RADIO CLUB OF AMERICA MEETING.

The last meeting of the Radio Club of America before the summer holidays was held May 29 in Fayerweather Hall, Columbia University.

NEW ARC FOR RADIO-TELEPHONY.

A new system of radio-telephony was recently put into operating condition by a Brooklyn inventor. Short distances up to five miles have been covered very successfully with this new system, which employs a special arc.

The telephone transmitter oscillation generator consists of a specially designed arc with a gas chamber that receives illuminating gas, and also ammonia gas under high pressure is sent through a small co-

Inventor Using His Improved Type Radiophone Arc.

axial hole in the metallic anode. This gas is used to maintain the oscillations steadily and at the same time to cool the arc, thereby eliminating the use of water for cooling the anode. A variable capacity and an inductance is shunted across the arc in such a manner that a continuous stream of oscillations is produced. The frequency of these oscillations was controlled by means of the variable capacity of the air dielectric type. The arc was operated on 11,000 volts A. C. and continuous oscillations with a constant amplitude are readily produced.

The variation of sound is produced by a specially designed water-cooled transmitter. Under operating conditions the transmitter has stood continuously three amperes without any sign of heating whatever. The receiving set was the ordinary crystal type with an inductance and a variable capacity. The inventor has found that a combination of galena and zincite gave the clearest sound in the receiving set.

Dr. Alfred N. Goldsmith, of the College of the City of New York, presented a most interesting and instructive paper on "Foreign Radio Apparatus." The paper was plentifully illustrated by lantern slides. The Telefunken, Goldschmidt, Lorenz and Poulsen, Berliner-Poulsen and Compaignie Générale Radiotelégraphique systems' apparatus were shown by lantern slides and later discussed by R. H. Marriott, B.S.; Dr. Zenneck, Dr. Wheeler and others.

A Wireless Lecture Set

A simple, yet effective, wireless lecture or demonstration set is always in great demand, and herewith is illustrated and described a satisfactory outfit of this type which can be built for a reasonable sum.

The apparatus comprises a filings coherer, a decoherer, two relays of about 75 to 100 ohms resistance or even less (but preferably of a much higher resistance than this), together with controlling switches, batteries and the electrical devices to be controlled by the relays.

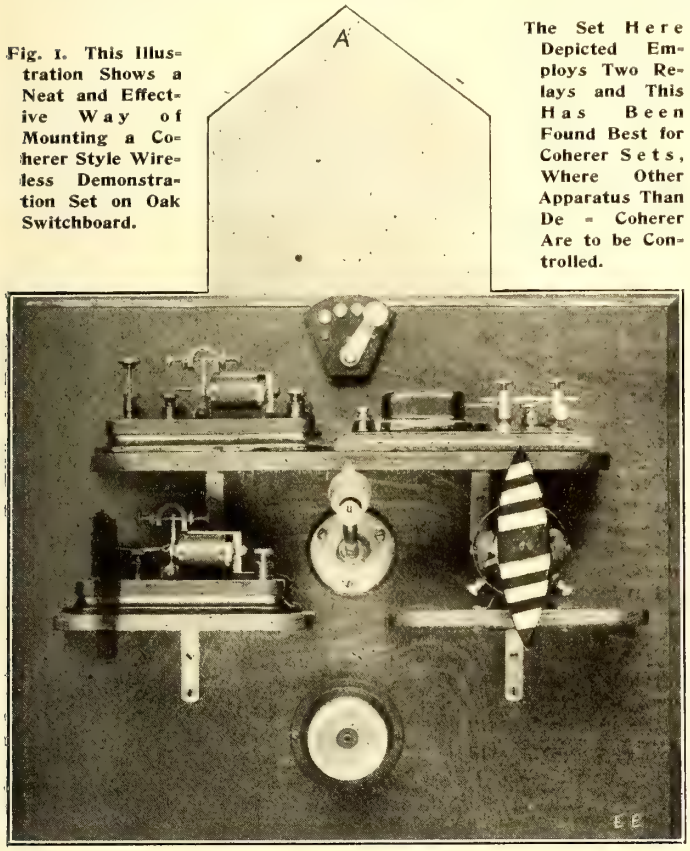

Fig. 1. This Illustration Shows a Neat and Effective Way of Mounting a Coherer Style Wireless Demonstration Set on Oak Switchboard.

The Set Here Depicted Employs Two Relays and This Has Been Found Best for Coherer Sets, Where Other Apparatus Than De - Coherer Are to be Controlled.

Fig. 1 shows a photograph of such a set, which works very nicely indeed. This is a good way in which to mount the various apparatus so as to be clearly seen by the audience; a couple of small shelves serve to support the instruments, as will be observed.

Referring to the diagram of connections for this outfit at Fig. 2, the general operation and arrangement of the set will be more clearly understood. A metal plate, which also shows in Fig. 1, and made of copper or aluminum, is indicated at "A." This plate may be about 12 inches square and any thickness.

The filings coherer "C" is tapped or decohered by the vibrating bell mechanism "D." Not more than one dry cell at "B1" should be connected in circuit with relay "R1" and the coherer.

It has been found best for such sets to use a second relay "R2" with which to control various demonstrative apparatus, such as electric whistle, lamps, motors, etc. These devices will be observed on the panel in Fig. 1, and the motor has a piece of metal fastened to the shaft so that its movement will be quickly and easily discerned. It is also a very good idea to mark some white bands on the strip of metal fastened to the motor shaft, so that its movement will be more quickly noticed.

The relays for this set are simply those known as "pony" telegraph type, etc., and while for short distances up to 50 to 75 feet it is not necessary to use any ground capacity "G" (corresponding in size to the metal plate "A" previously mentioned), this capacity should be used as shown in dotted line at Fig. 2 for greater distances than those mentioned. For distances above 150 to 200 feet it is best to use 10-15-foot brass tubes, etc., or a small aerial made of copper wire, etc., with a metal plate several feet square for the ground capacity or counterpoise. These sets, of course, should be operated, whenever possible, without any ground connection, as audiences in general are very skeptical on these matters, and if they find or see a direct ground connection they immediately believe that the apparatus is a fake.

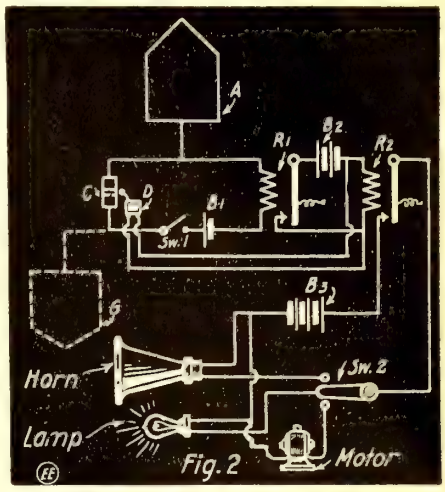

Fig. 2. Diagram of Coherer Set Connections.

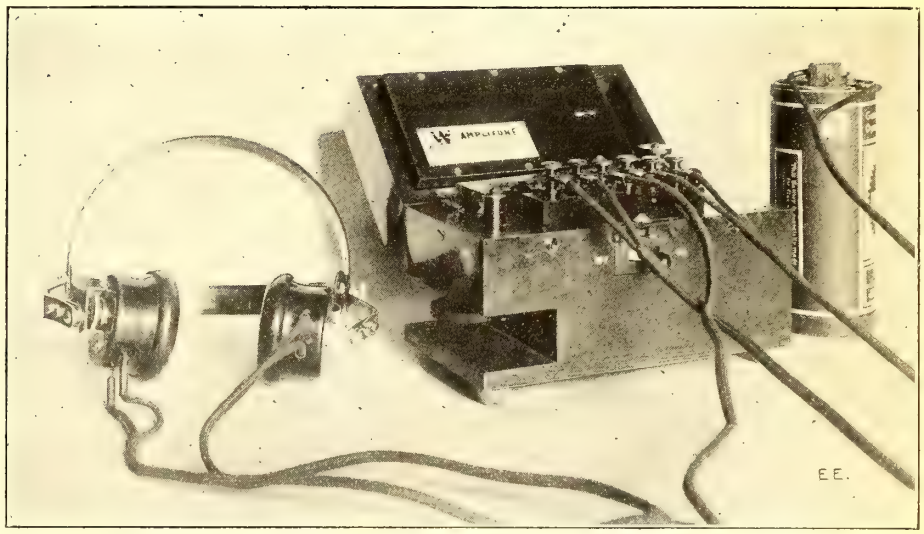
A 1-inch spark coil proves very good for the transmitter, and this is usually mounted on a 5 or 6-foot pole with batteries, so as to be carried through the audience, allowing anyone to press the push-button actuating the coil. A ball spark gap should always be used for these lecture sets. For an aerial a 3-foot brass tube may project above the coil and connect to one side of the spark gap. Two such tubes at right angles act well as "aerial" and "ground," connecting each to alternate sides of the spark gap.

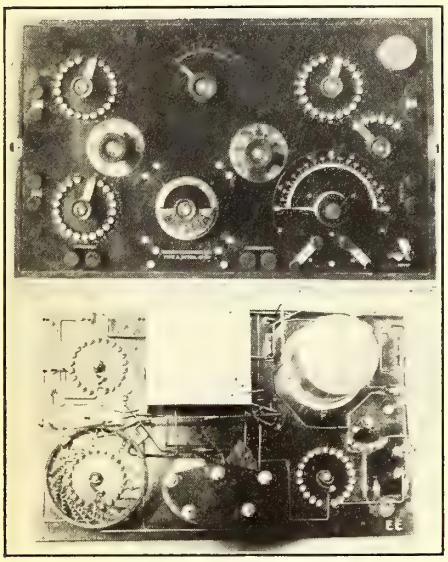


WIRELESS FROM NEW YORK TO BELMAR.

Randolph Miller, Edward Taylor and Frank E. Hoyer, all of Asbury Park, were appointed recently by Justice Kalisch, of the Supreme Court, as condemnation commissioners to fix the price of land wanted in Belmar, N. J., by the Marconi Telegraph Cable Co. for the establishment of a wireless station.

Application for the commissioners was made by John L. Grigg, president of the Marconi Co. The company's main station is at New Brunswick, and the justice was told that it was desired to establish wireless communication between Belmar and New York.

A MICROPHONIC RADIO-AMPLIFONE.



A new wireless amplifone for the amplification of received radio signals is herewith illustrated. This instrument was developed by a well-known American wireless company and it is extensively used in the United States navy and army. The principle upon which this amplifone works is that of the microphonic contact. There are within the box several microphones of special design and each one is connected in series with the next. The instrument is connected to the radio receiving set in place of the regular telephone receivers, and a battery is connected in series with the pair of phones and the microphones as shown. Each microphone amplifies the incoming signal with a different amplification strength until the last microphone stage amplifies it very considerably. By using more microphones the stronger the received signals will be amplified.

Standard Navy Type Amplifone Employing Extra Sensitive Microphones.

NEW U. S. NAVY RADIO RECEIVING SET.

Dr. Louis Cohen, of the Bureau of Standards, has recently perfected a new radio receiving set which has been adopted by the United States Navy as its standard receiving set. It is illustrated in Fig. 1.

(Above:) Fig. 1. Shows Front View of U. S. Navy Radio Receptor.
(Below:) Fig. 2. Rear View of Same.

The rear view is shown in Fig. 2. The connection of each individual instrument is represented in diagram Fig. 3, where A, C_1, L_1, constitute the primary or antenna circuit and C_2, L_2 constitute the secondary circuit. The two circuits are electrically linked together through two small condensers C_o, C_o, and any degree of coupling may be obtained by varying these condensers. This method of coupling offers several advantages. They are: (1) Compactness; (2) increased efficiency; (3) higher selectivity; (4) simplicity in operation. In regard to the first point it is quite obvious that by eliminating the receiving transformer, or loose coupler, a considerable economy in space may be accomplished, which makes it possible to build a receiving set of comparatively small dimensions for a large range in wave lengths. The second and third points have been definitely settled by a large number of comparative tests with other receivers of the best known types on the market.

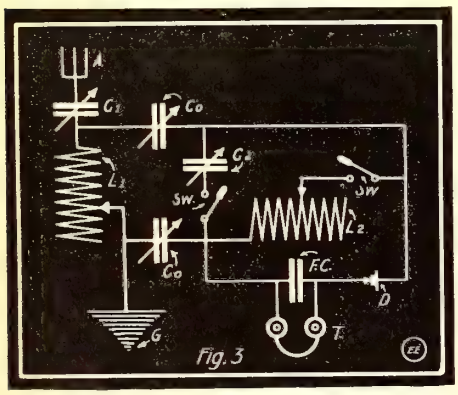


Fig. 3. Diagram of Dr. Cohen's Improved Navy Type Receiving Set.

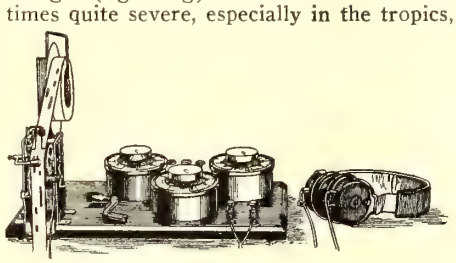
The instruments are mounted on a hard rubber board and are connected by stranded copper wires. Note that all the wires are placed as nearly at right angles as possible. This was done in order to prevent cross induction, which may occur. Any wave length from 150 meters to 4,000 meters can be obtained quickly with this receiving set.



Dr. Louis Cohen has done a considerable amount of work in tabulating formulae for the determination mathematically of inductance and capacity values, and his latest product in the form of an efficient radio set will undoubtedly be very extensively applied.

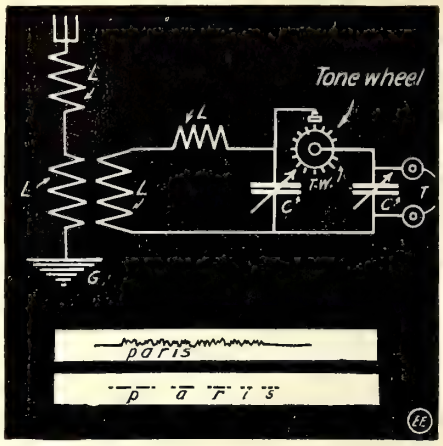
All of the coils and other parts, such as condensers, are calibrated in their correct electrical values, and the finish and workmanship are of the very highest standard.

A NEW WIRELESS CODE TEACHER.

An improved form of automatic wireless code teaching machine, known as the Raydeograph, has been perfected, which does not use buzzers or vibrators. The device is here illustrated and appears of great value in all-around teaching where students have no access to schools, etc. It is also used in schools.

It quite often happens, in wireless, that an operator is compelled to copy one station through the "jamming" or signals of a second station, in which case two signals are heard in the telephones at the same time. After considerable practise an operator can concentrate his mind on one signal and disregard the other. These aerographic conditions are produced by the double tapes provided with the Raydeograph to perfection, with the additional advantage that the intensity of the individual signals can be varied at will. The student may manipulate the controls so that the "jamming" signal is much weaker than the one he is copying, but as he becomes more proficient in the art of copying through interference he may increase the intensity of the "jamming" signal or decrease that of the one he is copying. Now, by copying first one series of characters through the "jamming" of the other series, then *vice versa*, it will be seen that each tape contains four code lessons. Another novel and decidedly practical Raydeograph feature is the Static Producer. It should first be explained that "static" or "x's" are false signals or an etherial disturbance caused by the effect of atmospheric electrical discharges (lightning). These "x's" are sometimes quite severe, especially in the tropics,

Improved Form of Radio Code Teacher.



and it is often necessary for an operator to copy a station or signals through this interference. The Static Producer causes disturbances in the telephones identical with these X's, and by manipulating the rear left Raydeograph control the intensity of this interference is varied.

While in use at the Amherst Branch of the Nova Scotia Technical Schools this instrument has operated successfully with 27 telephones in circuit. The machine is contained on a base 8x13 inches and may be mounted on a small table or desk.

The D. L. & W. R. R. recently conducted successful wireless telephone tests between a moving train and station set, over a range of 63 miles, in mountainous country. Regular business made up the messages.

THE GOLDSCHMIDT TONE WHEEL DETECTOR.

One of the cleverest and also simplest radio detectors, if so we may call it, used for the reception of undamped wireless waves is that known as the "Goldschmidt Tone Wheel." We show illustrations herewith (see Fig. 1) of this ingenious device, which consists of a metal disc with a large number of teeth cut in its outer periphery

(Above:) Fig. 2. Circuits Used With "Tone Wheel."
(Below:) Fig. 3. Tape Records of Radio Signals.

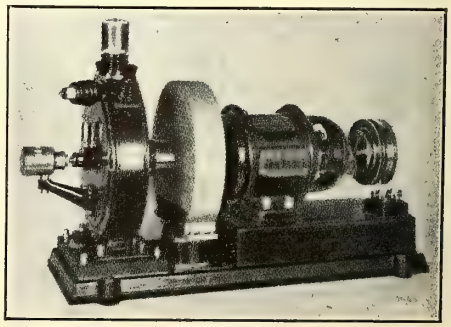
and a finely adjustable brush making contact with the edge of the rapidly rotating disc.

The operation of this device is as follows: A special motor drives the toothed disc at such a speed that, considering the number of teeth and the revolutions per second, the number of breaks in the circuit per second will be slightly lower or higher than the frequency in cycles per second of the incoming etheric wave.

Suppose, for instance, that the currents to be received have a frequency of 40,000 cycles per second. Then, if each tooth of the tone wheel has a width of 1 millimeter, there will be a synchronous rotation for a circumferential velocity of 40,000 times 1 millimeter or 40 meter-seconds.

Owing to the difficulties of producing a constantly synchronous rotation it has been arranged for the wheel to rotate at a slightly different value than the frequency of the incoming wave. As an example, a frequency of 39,000 or 41,000 could be used for a wave frequency of 40,000 cycles.

Then the frequency of the "note" heard in the telephone receiver in the circuit, shown at Fig. 2, would be what we might



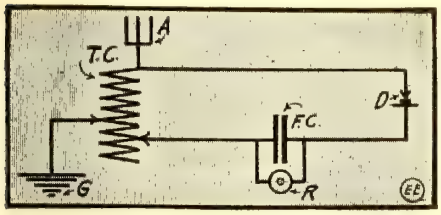


Fig. 1. The "Tone Wheel" is Driven by an Electric Motor at High Speed.

term for convenience the "beat" frequency, or the difference between, for instance, 40,000 and 39,000, or 1,000. Thus a perfectly audible tone is produced from a radio-frequency current which, of course, is far above audibility.

(*Continued on page* 109.)

A VACATION WIRELESS RECEIVING SET.

No doubt many of the wireless experimenters are about to go to the country on their vacations and they need not part with their instruments, as quite a compact receiving set can be readily made suitable for carrying about the same as a camera.

Circuit For Vacation Radio Set.

The case in which the instruments are placed is an ordinary hand valise, that can be obtained for about 50 cents, or a box of similar size. The instruments which comprise this set are an ordinary single slide tuning coil TC, a silicon detector D, fixed condenser FC, and a pair of 'phones R, of 2,000 ohms resistance, preferably. The tuning coil is fastened to the case by means of three screws, as shown. The detector and condenser are also fastened in the same manner. After the instruments are arranged connect them as in diagram.

The aerial or antenna should next be considered. There are several methods of erecting an aerial for temporary operations. One of these consists of flying a kite and attaching the aerial, in the form of a thin copper lead, such as No. 28 or 30 B. & S. gauge, to the kite string. Trees form good support for aerials. Sketch shows a method of supporting an aerial from a tree. Care should be taken to see that the wires do not touch any leaves or any part of the tree. The ground or earth connection can be made to any metallic body well grounded in moist earth, or a piece of pipe driven into the ground. If water pipes are available they should be used.

In using the set the detector is first adjusted until signals are received best, but a buzzer test is of course the quickest way to adjust it, and therefore it is advisable to install a buzzer test on this outfit. This set will be very useful to the experimenter in obtaining the latest baseball and other news and correct time signals, et cetera.

THE GOLDSCHMIDT TONE WHEEL DETECTOR.

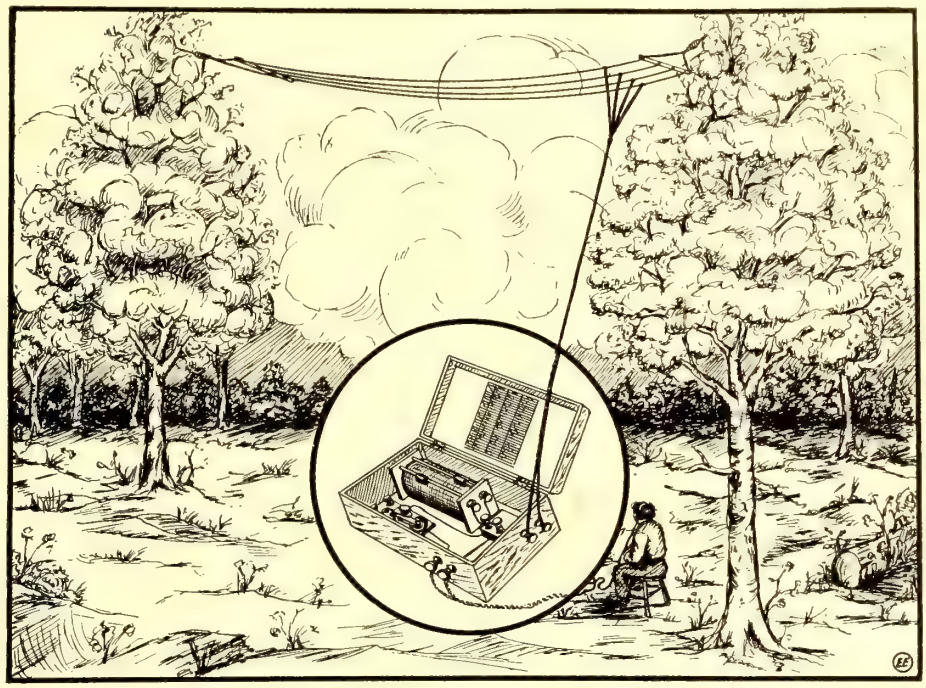
(*Continued from page* 108.)

If a suitable high-frequency A. C. galvanometer is placed in series with the tone-wheel circuit very excellent tape records may be taken of the dots and dashes, as Fig. 3 shows. These were registered photographically on a moving film.

The upper curve in Fig. 3 shows a record produced by means of an ordinary crystal detector, and the lower record shows the remarkable clearness of the signals registered with the tone-wheel receptor.

Although this machine has been repeatedly classed with that invented by Prof. R. A. Fessenden, known as the "Heterodyne," it does not operate on the same principle at all, as will be evident.

This tone wheel simply acts as a frequency changer, while the Heterodyne produces its results by the amplification due to superimposing a high-frequency alternating current on the radio-circuit, and "beats" are thus produced of low frequency which depend upon the difference between the frequency of the etheric wave and the superimposed artificial wave. No such beats are produced in the Goldschmidt device.



TALK BY WIRELESS PHONE 721 MILES.

Sponsored unofficially by the Secretary of the Navy, a wireless telephone invented by H. P. Dwyer, a San Francisco man, has carried the human voice 721 miles. The conversation was exchanged between the United States Government radio station at Mare Island and the Government station at Tatoosh, Cape Flattery, on the coast of Washington.

During the test Mr. Dwyer's voice was also heard at Bremerton, a distance of 560 miles; at Point Arguello, at Eureko and by the Government radio operator at San Diego.

The call sent from Mare Island was received on wireless telegraph sets, and the replies were telegraphed back. Through the perfection of certain parts of the new invention Dwyer says that it is possible to telephone in any kind of weather.

Mr. Dwyer asserts that he could have been heard at 1,000 miles if there had been a radio station to receive his message, and that with the proper aerial, 500 to 600 feet high, there is no reason why the human voice cannot be distinctly audible from San Francisco to Honolulu.

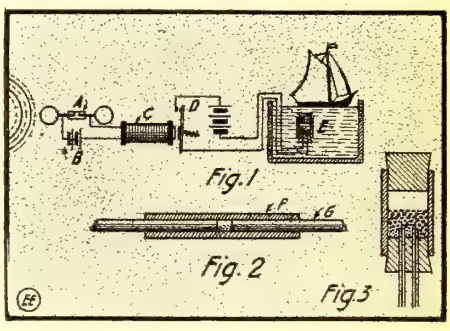
How Aerial May Be Erected Between Two Trees for Receiving Wireless Messages.

A round magnet coil contains the least resistance with a given core cross-sectional area.

BLOWING UP A TOY BOAT BY WIRELESS.

Here is a new and exciting sport for boys who know a little about electricity, especially for boys who have wireless apparatus. It was devised by Prof. Charles Forbes, of Columbia University, to prove that a submarine bomb cannot be exploded by wireless waves except through a special apparatus, says the *Sunday World*. With such apparatus, which is easily made at home, you can explode bombs under toy ships floating in the bathtub or a washbowl.

At Fig. 1 is shown a diagram of the apparatus for exploding a mine by wireless. A, coherer; B, primary batteries; C, relay; D, batteries of the relay; E, vessel of water containing miniature mine.



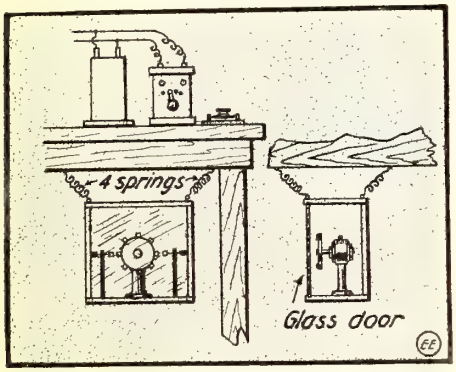
Anyone who has not a wireless apparatus can make use of an induction coil or a Leyden jar for producing the waves. A Branly tube arranged in series with two or three dry batteries will form the receiving apparatus, and this is completed with a relay from which wires run to the fuse of the mine.

The electric waves, whether real wireless or discharged from a Leyden jar, act upon the coherer, the battery of which closes the relay circuit. The coherer is made of a glass tube about 1½ inches long, into each end of which a rod of copper or brass is introduced. Between the ends of the rods there should be a space about $\frac{1}{16}$ inch long filled with filings (nine parts nickel and one part silver). Metal balls are fitted to the other ends of the rods. Such a coherer offers great resistance to the passage of the current from the battery, but the wireless waves greatly increase the conductivity of the filings, and this is enough to set the relay in action.

Fig. 2 shows details of the coherer; F, glass tube; GG, copper rods, and Fig. 3 the miniature submarine mine.

The mine is made as indicated in diagram Fig. 3. It is a metal tube about three-quarters of an inch long, closed at each end with a rubber cork and the space inside loaded with ordinary gunpowder. Through the lower cork the insulated wires from the relay battery are inserted, and

(*Continued on page* 110.)



Wireless Method of Blowing Up Miniature Ship.

MOUNTING SPARK GAPS TO ELIMINATE NOISE.

A very novel and at the same time effective method of mounting or, rather, suspending a rotary spark gap, has been made use of by a New York radio experimenter.

As the illustration shows quite clearly, the rotary gap with its motor is mounted in a substantial wooden cabinet with glass

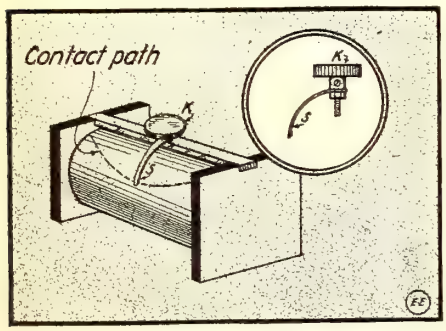
Spark Gap Noiselessly Suspended on Springs.

front and this cabinet is suspended on four strong spiral springs from the underside of the operating table.

The glass door on the cabinet should close tightly and, owing to the method of suspension used, practically no vibration noises are transmitted beyond the wireless room.

BLOWING UP A TOY BOAT BY WIRELESS.

(*Continued from page* 109.)



their ends are joined by a very fine wire of iron or platinum. This rests in the middle of the powder. As soon as the current passes through it becomes red hot and the powder explodes.

The mine is placed in the bathtub and a toy boat is sent sailing over it. At the right moment the Leyden jar is discharged, the coherer catches the waves of electricity, closing the main circuit; this actuates the relay, which sends the current of its batteries into the mine. This explodes and blows up the toy boat.

Such mines can, of course, be exploded by direct current from a battery, the circuit being completed with a telegraph key corresponding to harbor mines fired by electricity.

A ROTARY TUNING COIL SLIDER.

In the accompanying sketch is shown a

Simple Tuning Coil Slider.

type of rotary slider that can be used advantageously on tuning coils of average length and diameter. In the center of the slider bar of the tuning coil bore a hole of suitable diameter to pass an 8-32 machine screw. Then take a piece of 1-32x½-inch spring brass S about half the length of the tuning coil, and at one end of the spring bore a hole in order to secure it to the slider bar and knob K. With a little adjustment it will be found possible to have the end of the contact spring follow the circular path on the coil as indicated.

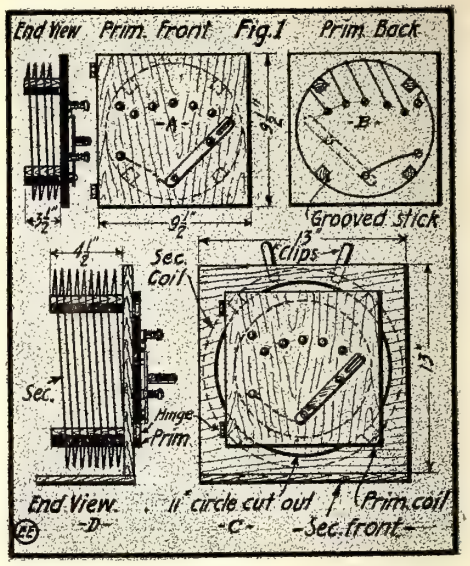
CHARLES F. ENGLER.

CONSTRUCTION OF A MERCURY TURBINE INTERRUPTER.

The main drawback in the construction and operation of spark coils is the interrupter. The interrupter here described is of the mercury turbine type, which can be used for very large spark coils.

The first thing to be made is the spiral tube A, Fig. 1. This is made of one-quarter inch brass tubing having a small internal diameter. It is then bent into a spiral as shown. This is readily done by placing the tube in a fire and then bending it to the required form. The ends (a) and (b), Fig. 2, are next bent as shown. The lower bend is used to suck the mercury in, while the upper bend is used to force the mercury out of. A round brass disc and a shaft are next made. The disc B is made 2 inches in diameter and ¼ inch thick. A ¼-inch shaft hole is drilled at the center. A ¼-inch brass shaft rod J is then inserted tightly in the disc. The spiral should next be placed on the disc and mechanically fastened (but not soldered) around as shown. Three brass strips C are secured around the spiral in order to strengthen the whole.

After these parts are completed the spiral is placed into a glass container. The spiral and shaft are supported by a brass collar D, Fig. 2, which is fastened by means of wood screws onto the cover E. A second contact F is next made, which consists of a brass sheet 1 inch wide. The segment F can be of different widths to give dif-



A Mercury Turbine Interrupter.

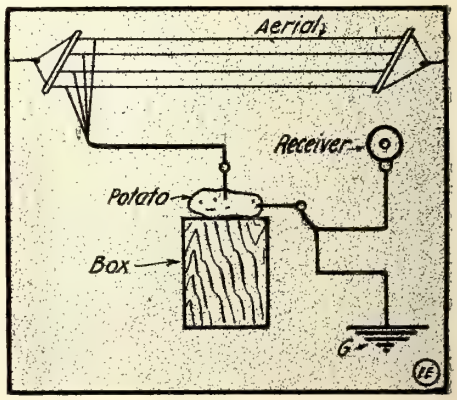
ferent results; so several of them should be made up.

The container is next filled with metallic mercury up to level L, and the shaft is rotated by means of a motor connected to the pulley G. The spark coil is connected in series with the source of power and the mercury interrupter from binding posts H H. When this interrupter is properly built it will interrupt the primary circuit between 300 and 2,000 interruptions per minute, depending upon the speed that the spiral is revolving at. The usual primary condenser is connected across the posts H H, and is best of the adjustable type for good results, especially when different width segments are used. The mercury will combine with solder, so the spiral must be mechanically braced or else brazed with *brass* solder.

A PROF. MODEL OSCILLATION TRANSFORMER.

A very efficient oscillation transformer may be made in the following manner. By a close study of the diagrams a good idea of its construction may be obtained.

Efficient Form of Oscillation Transformer.



The base and other wooden parts should be made from good dry oak or other hard wood. The primary (Fig. 1) is wound with five turns of No. 6 aluminum helix wire with half-inch spacing. Each turn is tapped and brought to a five-point switch on the front (Fig. 1a) so that the wave length can easily be regulated.

The secondary is wound with eight turns of No. 6 or No. 8 aluminum wire, spaced about one-half inch, and is adjusted by two clips (see Fig. 1c).

Submitted by PAUL FLEHR.

A POTATO DETECTOR.

While putting up an aerial in my yard (80 feet long and 60 feet high) recently I tried to receive wireless messages. I took a potato and placed it on a box. Then I took two sewing needles. I took one needle and stuck it into one side of the potato. I then connected the second needle with one pole of the receiver and stuck it in the other end of the potato. I took the ground wire and connected it with the other end of the pole of the receiver, and when this was

A Potato Acts As Wireless Detector.

completed I was able to receive many messages just as clearly as from a detector.

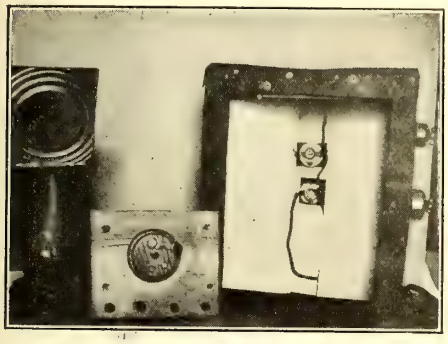
(An electrolytic action, no doubt.—*Editor.*)

HOW-TO-MAKE-IT DEPARTMENT



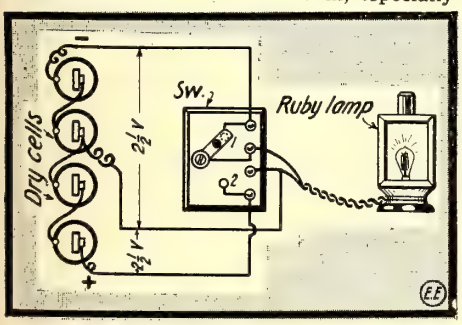
This department will award the following monthly prices: FIRST PRIZE $3.00; SECOND PRIZE $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

SECOND PRIZE $2.00.

AN IDEAL ELECTRIC RUBY LAMP.

The lighting system which I am sending herewith is one I have in use at the present time and I would never be without it.

My first experiment was with an old oil ruby lamp converted into an electric lamp,



Electric Ruby Lamps For the Amateur Photographer.

as I have illustrated in drawing. In this drawing will be seen a two-point switch, mounted on a small board having four binding posts, for making quick connections.

With the aid of this board I have used four dry cells for almost a year by simply throwing the switch from one point to the other, whenever I think of it while in the dark room, which allows two cells to rest while the other two are working. This should be a great relief to any amateur photographer, and can be used also where continuous service is required, when dry batteries only are at hand.

At present I am using a lamp which I have made of a soap box of suitable size for holding an 8x10 ruby glass, in which I have two miniature lamps, and two snap switches on outside of box, one for each lamp, so that if one lamp should happen to burn out while at work I can use the other; or I can use both, if desired. The switchboard can be attached to back of lamp box if necessary. Many an amateur dreads the work in a dark room, especially

Wiring of Dry Batteries for Ruby Lamp.

in hot weather, with the oil lamp, which adds to his discomfort.

Contributed by VICTOR A. SCHYE.

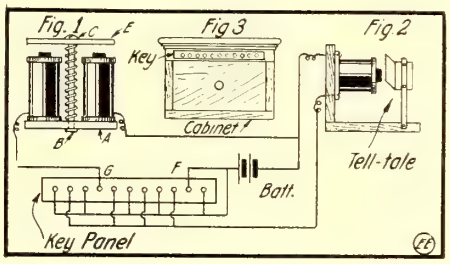
L. John Block of Cincinnati, Ohio, writes as follows:

"I must say the *'Electrical Experimenter'* is some Magazine. The best ever in my opinion."

FIRST PRIZE $3.00.

SIMPLE ELECTRIC DRAWER-LOCK AND TELL-TALE SIGNAL.

The following is the description of an electric lock and tell-tale signal which I constructed for use in my workshop and have used for some time.



Looking at Fig. 1, A represents two magnets (I used some from bells) with the yoke drilled at B for a 1½x$\frac{3}{16}$-inch roundhead stove bolt C, which is fastened at bottom side of magnet by a nut.

A light spring D with the nut at top of bolt holds a piece of ⅛-inch iron E away from magnets until the current magnetizes and draws the iron down, thereby unlocking the drawer.

Having finished the lock, we may now turn our attention to the key, or secret switch, which unlocks the drawer. On the top part of the drawer place a thin strip of wood with brass upholstery tacks mounted and wired as shown.

By looking at the diagram it will be seen that in order to open the drawer a connection has got to be made between F and G, as all other wires connect with the tell-tale signal shown in Fig. 2.

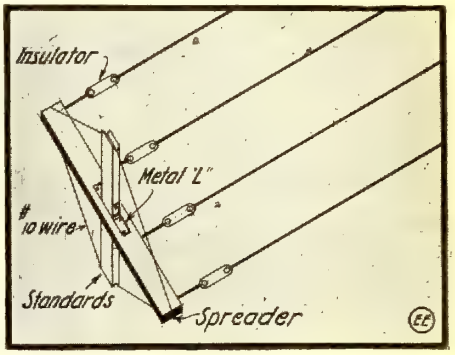
This is merely a single magnet mounted on a strip of wood with a small piece of

Magnetic Lock and Tell-tale for Drawers.

light iron mounted on a stick which is hinged on the bottom so that the current will draw the iron strip onto the magnet. This magnet I have enclosed, together with two dry cells, in a box and placed behind the cabinet so that if a stranger opened the drawer he could not reset the signal.

This device has given excellent service, besides saving me the price of an expensive lock and, although it has been in use for a long time, both signal and lock are in good condition. Contributed by

GEORGE H. ROBERTS.



STATIC ELECTRICITY FROM SUIT CASE.

I thought I would tell you of a strange experiment in static electricity I have made accidentally. I have a leather suit case which I carry around daily. I have noticed while walking, if I brought my finger close to the suit case brass lock I felt a slight twinge. For a long while I wondered what the cause of this was. Finally I arrived at the conclusion that the suit case continually rubbing against my woolen coat caused a charge of static electricity, which stored itself in the lock. Then when the finger was brought close to the lock it discharged itself into the body, and thence into the ground. E. CAPILLON.

THIRD PRIZE $1.00.

BRACE FOR AERIAL SPREADERS.

The illustration shows the method I use to prevent my 12-foot spreaders from warping. Two wooden standards one foot long are screwed to the center of the spreader, over which is drawn a No. 10

Aerial Spreader Strengthening.

copper wire. I have been using such an arrangement for a year with perfect satisfaction.

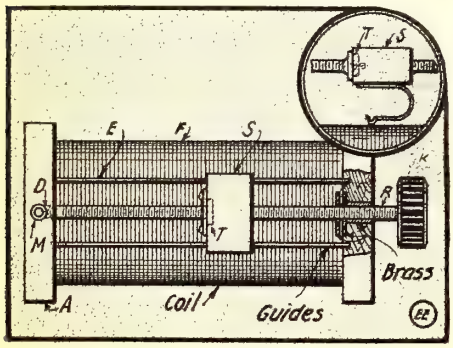
ARTHUR R. DARLING.

A SIMPLE ELECTRIC CHIME.

A simple but harmonic electric chime can be made by anyone. The following material will be needed in constructing this simple chime: Two pieces of oak, 12x5x¾ inches; 10 strips of white wood, 8x2x½ inches; 10 electric bells, with gongs removed; 10 pushbuttons, 10 brass tubes, ¾-inch in diameter; the largest tube should be 7 inches long and the smallest tube 2 inches long, while the other tubes should vary in ½-inch lengths.

Arrange the apparatus as shown in figure.

An Electric Chime.



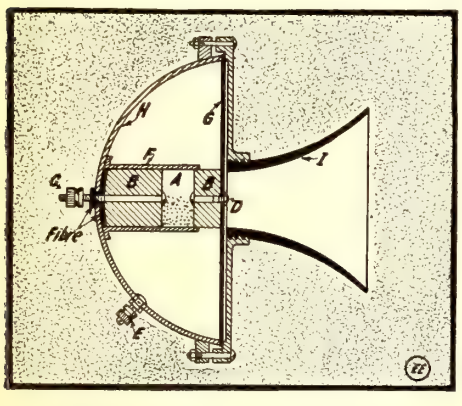
Care should be taken to allow the brass tubes to swing freely, as the tone of the tubes depends upon the vibrations received from the striking of the clapper. The connections are shown in sketch. The tubes are best hung on strings.

A PRECISION TUNING INDUCTANCE.

When it is desired to tune finely a certain circuit the knob K is turned, and also the threaded rod turns. Because it is fixed and cannot move, the nut T (and consequently the slider S) is moved up and down the coil at will. It is recommended that as coarse a pitch or spiral as possible be used, of the type used in automatic drills, etc. Thus the maximum of movement of the slider is obtained by minimum movement of the knob.

The rod R, being pivoted in D, makes contact therewith. The bolt M of binding post completes the connection.

A double or triple slide coil may be operated in this manner by reducing the dimensions (diameter) of rods R and E E, and of slider S.



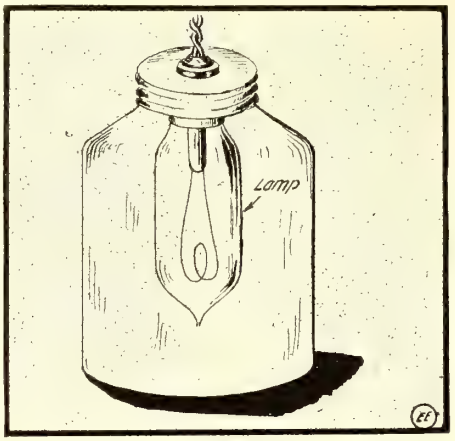
Finely Adjustable Tuning Coil.

The whole coil may be enclosed by thin wooden sides. It then presents a very neat appearance. No iron should be used in the construction of this tuner. Contributed by

A. D. R. FRASER.

MAKING A TELEPHONE TRANSMITTER.

The diagram shows how I made a simple telephone transmitter. H, the case, is a gong from an old bell; B. B are two pieces of carbon cut from an old battery, each having a hole in the center; F is a paper tube to hold the crushed carbon or better regular carbon granules A. D is a binding post to hold the carbon button to the diaphragm G, which is made of tin or ferro-type iron cut to the right size and held by a wooden ring as indicated. At C is a binding post holding the button B to the back of the gong, from which the button and post are carefully insulated. E designates a binding post attached directly to the gong and forms the other connection for the circuit. I is the mouthpiece. The diagram is self-explanatory.

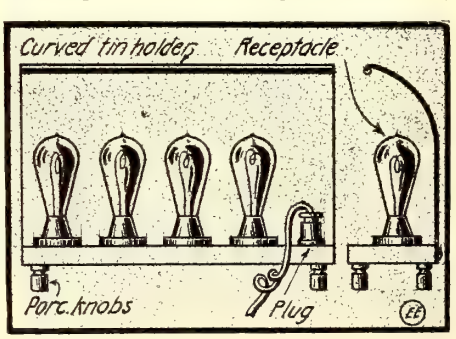


Microphone Made Out of Bell Gong.

Contributed by ALLEN SJOHOLM.

A RUGGED DARK-ROOM LAMP.

Procure an ordinary two-quart glass fruit jar, break out the porcelain lining in the cover and cut a hole through the metal just large enough to fit over the socket as shown. Then solder cover and socket together. Line the inside of the jar with two thicknesses of orange paper. One can almost use an 8-C. P. lamp, but the best is a 4-C. P. lamp. Screw the lamp into the socket and turn the cover onto the jar. With cord and plug of proper length the light can be readily moved where needed about the dark-room table.



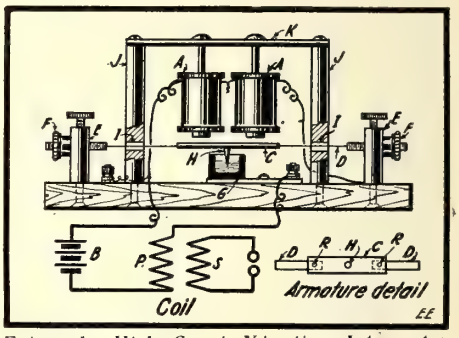
Dark Room Ruby Lamp in a Bottle. Hard to Upset.

HOW TO MAKE AN ELECTRIC HEATER.

Everyone appreciates the grateful heat and cheerful glow of the luminous electric heater or the modern open fire. It is very useful wherever a small amount of heat is desired quickly. The home-made electric heater here described is especially desirable for the sickroom, nursery and cozy corners.

Procure about 4 to 5 porcelain lamp receptacles and mount these on a hardwood base. When you mount the receptacles remember that the width between them should be large enough to allow the lamp bulbs to be screwed in and out without trouble.

Connect receptacles in parallel as shown in drawing. The last socket is left without a lamp, as this one will receive the plug. The other end of the cord has also a plug for current connection. When all is finished so far, make from sheet tin or polished copper a hood as shown in drawing. The purpose of this hood is to reflect the heat which the lamps develop. The amount of heat can be varied by using higher candle-power lamps and the heat can also be regulated by partly unscrewing some of the lamps. The more lamps there are on, the more heat, and vice versa. Porcelain knobs are best screwed under the base to act as feet in supporting the heater above the floor. If the most cheerful effect is desired frosted globes can be employed.

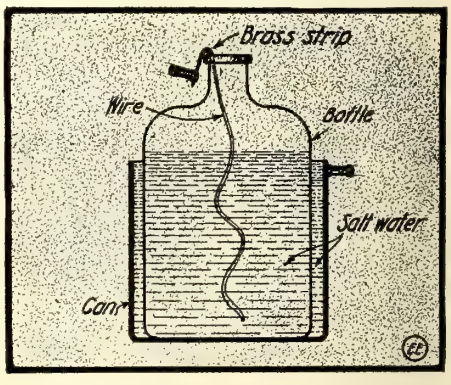


Electric Lamp Stove For the Chilly Evenings.

MAKING A HIGH SPEED INTERRUPTER.

In the accompanying drawing is shown an interrupter for producing extra high frequencies. This interrupter when properly made will interrupt circuits from 50 to 600 periods per second.

At A A are two magnets taken from an old electric bell which are supported on an iron yoke K, as shown. C is the armature, made from a piece of soft iron about No. 20 gauge. An ordinary steel pin H is riveted to the center of this armature. Two short pieces of brass spring D D are then riveted to the ends of the armature by two small rivets R R. The standards E E and J J are made of brass. Two holes I I are drilled through each standard J J. These holes are to be made large enough to let the brass springs D D vibrate freely. A small brass cup is taken from an old battery and should be fastened to the base, as shown at G. Now fill the cup about three-quarters full of mercury and connect as indicated. Any frequency may be obtained just by varying the tension of the two springs D D. Two No. 8-32 screws slip through holes in posts E, having clamping screws. Fine tension adjustment is affected by thumb-nuts F. This interrupter works very good in connection with medical wireless coils or X-ray coils.

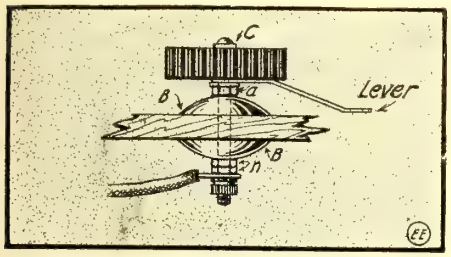


Extremely High Speed Vibrating Interrupter.

A CHEAP BUT EFFICIENT SENDING CONDENSER.

The parts needed for this condenser can be found in nearly every home. It consists of a tin can, a large bottle free from flaws, two binding posts, wire and salt water. Little need be said, as the diagram speaks for itself. The salt water acts the same as the tinfoil in Leyden jars. With one of these condensers, a 1-inch coil and no helix, I get a very good spark.

Contributed by RAY ATKINS.



Salt Water Type Leyden Jar.

A HOME-MADE SWITCH LEVER.

An efficient switch lever for use on loose couplers inductive tuners, etc., having a much neater appearance than the ordinary lever, can be constructed cheaply in the following manner:

A brass lever is cut from a piece of sheet brass 2" long, ½" wide at one end, ⅜" wide at the other; the narrow end is rounded slightly. A ⅛" hole is bored in the wide end.

The thumb screw is made from a black checker 1¼" in diameter; the plain side is turned up and a ⅛" hole bored in its center. A stove bolt 1⅜" long and ⅛" in diameter, threaded its entire length, is slipped through the checker and the brass lever secured firmly to the bottom of the checker by the nut "a," as shown in the

Switch Construction for Tuners, Etc.

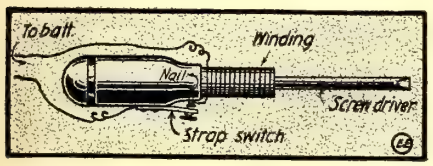


figure. A small washer had better be used, as shown at "c," to prevent the head of the bolt from pulling through the checker.

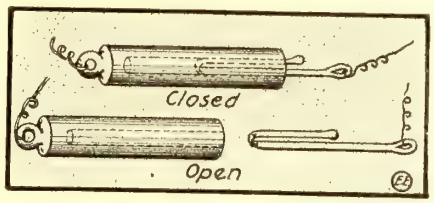
Two tin roofing caps "B," with ⅛" holes in their centers, are used to grip the surface tightly, of whatever they are attached to. Three nuts, "n,n,n," are now needed; one to tighten the bolt properly, the other for a check nut to hold the first, and the third to clamp the wire connection.

Contributed by
ARTHUR R. DARLING.

AN ELECTRO-MAGNETIC SCREW-DRIVER.

A magnetic screwdriver is very convenient in starting screws in places difficult to get at. The magnetic screwdriver herewith shown is simple to fit up. At first, wrap the steel shank with a layer of paper or tape and then wind evenly four layers of No. 24-gauge copper magnet wire,



This Screwdriver Holds Screws on Its End by Magnetism.

which can be obtained in any electrical store. After the wire has been wound, make a strap key of brass or other conductive material. A small rubber knob is next placed on the end of the strap key as shown. This key is then fastened to the handle by means of brass screws. A small tack or flat-head screw is hammered on the handle in order to make the second contact. One of the wires from the coil of wire is connected to this tack, while the other wire is brought to the end of the handle. Another wire is connected to the strap key and both of these wires are braided together. These wires are taped to the handle with friction tape as shown. Every experimenter and electrician should have a screwdriver of this kind in his shop or laboratory tool kit, as a great deal of time is saved with it. The drawing is self-explanatory. A few dry cells will supply the necessary current required.

A HANDY ELECTRIC COUPLING.

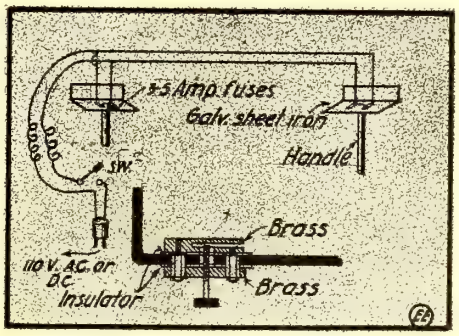
A very useful electric coupling can be made from a clasp such as that used in fastening bead necklaces. They are generally made with a small ring on each half for fastening to the necklace, and the electric wire can be easily twisted around these rings. Also it is easy to make similar

Easily Made Electric Connector.

couplings for battery circuits on the style illustrated from a piece of brass tube and flat brass spring bent U shaped.

METHOD OF PREPARING LEAD PEROXIDE.

Carefully treat "red lead" with pure nitric acid ($H NO_3$). Collect the remaining substance when the acid has been poured off; wash it well and filter it carefully, drying until it is a thick paste. Now mould it into pellets in a piece of glass tube with a wooden rammer. Dry and place in detector stand. Contributed by
A. D. R. FRASER.



ELECTRICAL IGNITER FOR FLASHLIGHT.

As there are many photographers taking photographs where considerable quantities of flashlight powder is to be used, the following description of a very simple electric igniter may not be amiss:

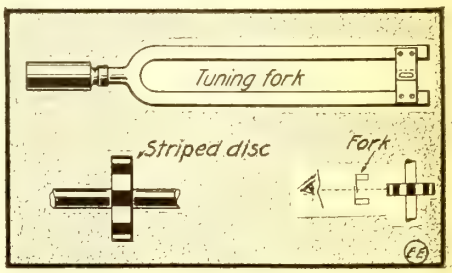
As the sketch indicates, a right-angled sheet iron tray is mounted on a handle and in the center of the tray is placed two insulated brass clamps or contacts. These contacts are electrically connected to a piece of standard lamp cord, which may be joined by an attachment plug into any electric lamp socket.

Some small lead fuse wire of about 3 amperes capacity, or better, 1 ampere size, is spread across the small space, about 1 inch long, between the connection clamps.

When the current is turned on by a switch in the circuit or the key on the socket into which the cord terminal is

Electric Igniter for Photo Flash Powder.

plugged, the fuse wire is melted and ignites the flash powder.



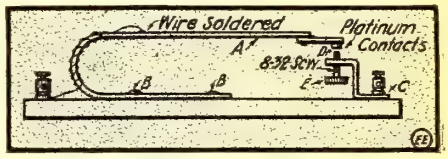
This arrangement has been used practically, with excellent results, by one of the largest commercial photographers in the country.

The New York-San Francisco telephone line is 3,390 miles long. There are two circuits, each using 6,780 miles of hard-drawn copper wire.

TUNING FORK AS SYNCHRONOSCOPE.

Probably one of the simplest ways of judging the synchronism of an A. C. induction motor, especially when the motor is of the synchronous type as used in talking picture machines, is here described.

This consists simply of a large tuning fork about 1 foot long, which is struck smartly on the hand, and at the two free ends of the fork two metal leaves pass each other in a vibratory manner. In these two leaves there are two slots about ⅜ inch long by 1/32 inch wide. To check the motor speed, which motor, by the way, has a rotating disc on the shaft painted alternately with black and white stripes about ½ inch wide, as shown in illustration, this



Tuning Fork Forms Simple Synchronoscope.

disc is viewed through the vibrating slits just mentioned. If the motor is in perfect synchronism with the A. C. supply and with the generator at the other end of the line, the stripes on the rotating disc appear to be stationary. If the motor is running faster than it should the disc appears to drift forward. If it is running too slow the rotating striped disc appears to move backward, or vice versa, depending upon the direction of rotation of the motor.

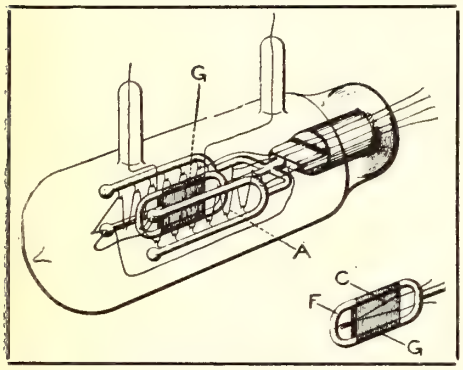
Of course the tuning fork used must be of the proper vibration note, corresponding to the frequency of the motor current, or rather the synchronous speed of the motor and the number of stripes on the disc. Any physics book gives these frequency equivalents.

A SIMPLE ELECTRIC FLASHER.

Here is a simple and cheap flasher for

A Thermostatic Electric Flasher.

use on battery circuits, for flashing small battery lamps or any other purpose that may suggest itself to the experimenter.



At A is a piece of steel ½x⅛x8 inches; B are two wood screws; C is a piece of brass; D, platinum contacts, and E, a set screw for adjusting this device. The winding is composed of about 8 feet of No. 36 single silk-covered wire. One end is connected to the binding post and the other end soldered to the spring, as shown.

When more than about 1½ amperes flow through the fine winding the latter heats up and causes the spring to bend so as to break the circuit at the contacts. When it cools off the spring straightens out again and closes the circuit.

This opening and closing action repeats itself every few seconds when the apparatus is properly adjusted. Different sizes of part A, and also the wire used, should be tried for various requirements until the best results are obtained.

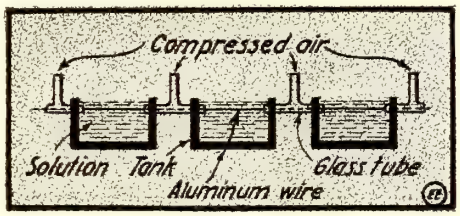
PURE ELECTRON DISCHARGE FOR WIRELESS TELEGRAPHY AND TELEPHONY.

The electron emission from heated metals at very low pressure has been investigated by scientists for many years, and the observations have been generally explained to be the result of chemical reactions with slight traces of gas. In the first half of an article by Dr. Irving Langmuir, and which is arranged in the form of a historical review, are related the experiments leading to the conclusion of the existence of pure electron emission in even the highest attainable vacua. After outlining the fundamental principles which govern this phenomenon the author shows how, through the medium of the *kenotron* (a hot-filament vacuum rectifier) and the *pliotron* (a new type of amplifier), both of which employ the pure electron emission from heated metals in extremely high vacua, a very simple and successful equipment has been produced to send and receive radio-telegraphic and radio-telephonic messages by trigger control of the tube. As much as 2 k.w. can be controlled in this way by an ordinary microphone.

The New "Pliotron" Vacuum Bulb Rectifier For Wireless Work.

In the construction of *pliotrons* it has been found desirable to make the wires constituting the grid of as small cross-section as possible. In this way, even when a positive potential is applied to the grid, the current that flows to the grid may be made extremely small. The use of very fine wire is made possible by using a frame of glass, metal or other suitable material to support the grid. Thus, in figure, the filament G is mounted in the center of a frame made of glass rods, on which the fine grid wire is wound by means of a lathe. The grid may thus consist of tungsten wires of a diameter as small as 0.01 mm., and these may be spaced as close as 100 turns per centimeter, or even more. —*General Electric Review.*

SPEED OF WIRELESS.



A paper presented before the French Academy of Sciences on the speed of propagation of the waves used in wireless telegraphy over the surface of the earth. The method used is as follows: Station 1 emits a signal to which Station 2 replies by a second signal. In Station 1 the time T_1 is measured between the departure of the first signal and the arrival of the second, and in Station 2 the time T_2 is measured between the reception of the first and the emission of the second signal. The time $T_1 - T_2$ is the time of transmission of the first signal from 1 to 2 and of the return signal from 2 to 1. The time $T_1 - T_2$ are measured by means of photographic microgalvanometers. By this method it is possible to measure the interval of time with an absolute precision which may become 0.00001 second. The wireless-telegraph waves are propagated over the surface of the earth with a speed apparently slightly less than the speed of light.—*Electrical World.*

ELECTROLYTIC INSULATION OF ALUMINUM WIRE.

An interesting use of the oxide film always present on aluminum wire and methods of artificially building up this film, which serves as an electric insulator, is described by C. E. Skinner and L. W. Chubb.

Numerous kinds of electrolytic baths were tried by the authors of the paper, and considerable practical results obtained. The film insulation, even after being built up, as explained, is very thin, and thus a considerable saving in the space factor is possible.

In the subsequent development continuous methods were employed in which the wire as an anode was drawn through a bath of electrolyte. In all the earlier methods of treating the wire passed over several sheaves with the result that it became hardened in the process. A straight-through method, as shown in the figure, was, therefore, tried and found to give very satisfactory results. Five tanks arranged in a straight line were used. The first and last contained hot water for washing and the middle three electrolyte. The wire passed from tank to tank through glass tubes and the solutions were kept apart by blowing air through a tube sealed to the center of the connecting tubes. In this method there was again no column of electrolyte at the point of entrance, and it was at first necessary to form the coating in two steps of 200 and 400 volts respectively. This was superseded by the present method in which the wire also goes straight through and the increase in voltage is again established through a small weir and spout through which the wire enters. This latest apparatus has the additional advantage of allowing the removal and starting of the wire without threading through.—*The Electrician,* London.

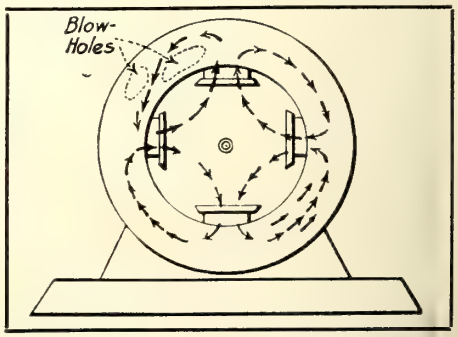
Method of Insulating Aluminum Wire Electrolytically.

ELECTROLYTIC PRODUCTION OF OXYGEN.

Several factories in St. Louis are now engaged in the electrolytic production of the commercial oxygen gas. According to the *"Engineer"* the electrolyte used is a 10 or 15 per cent. solution of either caustic soda or caustic potash. As direct current traverses the electrolyte the oxygen given off at one electrode is collected and compressed, while the hydrogen given off at the other electrode is allowed to escape. In one well-equipped oxygen factory in St. Louis it is claimed that the oxygen company can produce about three cubic feet of oxygen gas for each kilowatt-hour used.

GALVANIC CELL WHICH REVERSES ITS POLARITY.

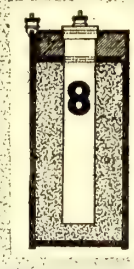
When two plates—one of zinc and the other of tinned copper coated on one surface with selenium and varnished with enamel over the remainder of its surface—are immersed in tap water the electric current through a galvanometer connected to the plates shows that in the dark the zinc is electro-positive to the selenium, while the result of light falling on the selenium is to increase the effect, says A. A. Campbell-Swinton in *The Electrician,* London. If, however, instead of zinc, carbon or copper is employed for the non-coated plate, the interesting result is obtained that, while the selenium proves to be electro-positive to the carbon or copper in the dark, it immediately becomes electro-negative to carbon or to copper when it is illuminated, this being easily shown by the deflections of the galvanometer in contrary directions as the light is turned on and off.



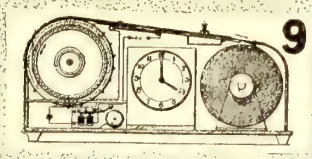
SLOW CATHODE RAYS.

In a recent lecture by Sir J. J. Thomson, at the Royal Institution, London, the electron discharge at different voltages, in a Coolidge type evacuated bulb were described. A curve was given which showed the relation between the voltage applied and the number of negative electrons radiated. The curve and also the experiments made, indicated that at least 15 volts was necessary to produce any appreciable radiation.—*The Electrician,* London.

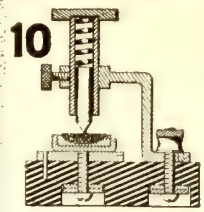
A horse is very sensitive to electrical shocks and nearly always succumbs to 550 volt current. About 1,800 volts is required to kill a man ordinarily in the electric chair.

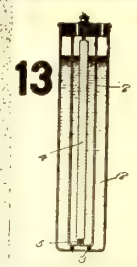


X-RAY TO LOCATE CAUSE OF BRUSH TROUBLES.



In electrical machines with cast iron or steel frames blow-holes may be present and may be large enough to increase greatly the reluctance of a section of the magnetic circuit. The reluctance being higher in one section of the circuit than in others will cause a lower voltage to be developed in a corresponding section of the armature, and local circulating currents will result. The blow-holes being concealed, it has often been found quite difficult to determine definitely whether or not they are the real cause of the trouble. According to E. H. Martindale, of the National Carbon Company, says *Electrical World,* steps are now being taken to use X-ray machines to search for blow-holes in machine castings whenever it is suspected that high reluctance in the magnetic circuit is causing brush trouble.





X-Rays Show up Blow Holes in Dynamo Castings.

A Brief Digest of the Latest Electrical Patents

LAMINATED IRON CORE (Fig. 1)—An arrangement of iron laminations in cores, making joints come in proper relation to magnetic flux path.

AUTOMATIC FIRE ALARM (Fig. 2)—A simple method to notify "Central" when a fire occurs at a subscriber's house. A fusible strip supports the receiver bracket, as shown.

TELEPHONE REPEATER (Fig. 3)—Improved form of telephone relay acting differentially. The magnet coil attracts armature, joined by levers to double action microphone.

ELECTRIC LOCOMOTIVE (Fig. 4)—This patent relates to the support of powerful electric motors above locomotive driving wheels, as shown, similar to the Pennsylvania Railroad type.

ELECTROLYTIC INTERRUPTER (Fig. 5)—Improvement in electrolytic interrupter consisting of one or more anodes, projecting upward as seen, in the bottom of the electrolyte container. Cathode enters at the top of container. This idea allows the gas bubbles to arise freely from the anodes.

SPARK-PLUG TROUBLE DETECTOR (Fig. 6)—A device to be used on motor cars, etc., connected in the sparking circuits, so that each spark may be observed as it passes through this series detector.

MAGNETIC VALVE (Fig. 7)—An electro-magnet is arranged to operate steam, gas or water valve, as shown, and also is provided with switch attachment, etc., for closing and opening circuit.

DRY CELL (Fig. 8)—Improvement in dry cell manufacture by which a rigid disc is placed tightly in the upper portion of cell against the mixture in order to retain same firmly.

ELECTRIC APPOINTMENT ANNOUNCER (Fig. 9)—A novel appointment announcer which operates by means of perforated paper strips, a clock, together with electric bell and battery.

RADIO DETECTOR (Fig. 10)—New "Pickard" detector, covering particularly the adjustment of contact point on mineral. Several movements are possible for the point.

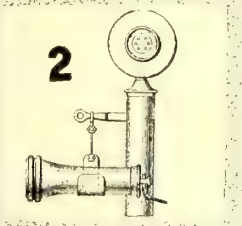
ATTACHMENT FOR TELEPHONE TRANSMITTER (Fig. 11)—A hinged cover is provided for use on telephone transmitter mouthpieces, presumably to keep the dust out, etc.

MAGNETIC SEPARATOR (Fig. 12)—Useful form of magnetic separator for removing iron filings from brass, etc. Brass sleeve (4) can be slid down by handle (6) so as to throw off iron after it has been attracted.

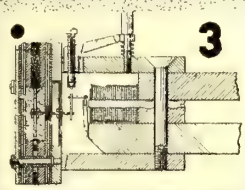
STORAGE BATTERY (Fig. 13)—Comprises an outer shell with zinc amalgam on the inner surface, constituting a negative electrode; also inner shell having an outer surface of copper amalgam for the positive electrode. Inner surface of inner shell is zinc amalgam with lead plate within it, constituting the negative electrode.

MAGNETIC CLUTCH FOR SHAFTS (Fig. 14)—Strong magnet coil controllable from switch and battery, etc., causes two parts of clutch to be held together magnetically and vice versa.

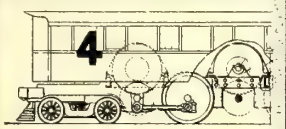
ELECTRIC HORN (Fig. 15)—Diaphragm is vibrated by means of tooth on center of same, coming in contact mechanically with revolving toothed armature of electric motor, as seen.



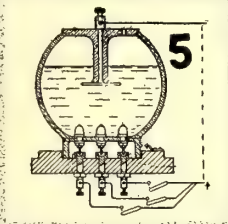
ELECTRO-PNEUMATIC HORN (Fig. 16)—A clever combination of electric and pneumatic horn, which is very compact. Can be actuated either by air bulb or electric button.



ELECTRIC WATER FOUNTAIN (Fig. 17)—Water fountain, having electric pump to circulate water through nozzle, etc., and also provided with electric lamp in center of water for illuminating effects.

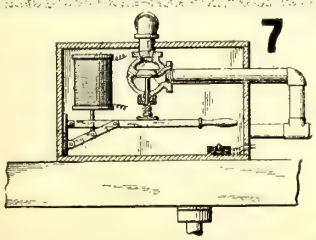


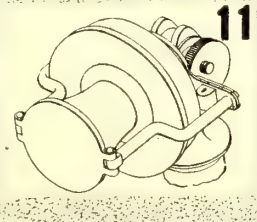
OSCILLATING FAN (Fig. 18)—Improved form of oscillating electric fan. Fan motor has gear attachment to cause same to be mechanically oscillated to and fro, in the usual manner.

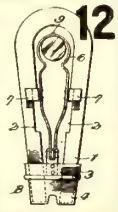


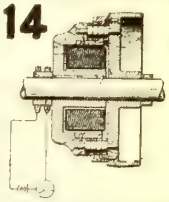
TELEGRAPH KEY (Fig. 19)—Vibrating form of speed telegraph key arranged to automatically close the circuit for certain length of time, as for dots and dashes.

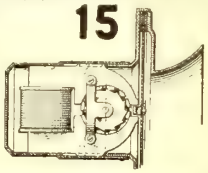
(Copies of any of the above patents will be supplied at 10c. each by the publishers.)

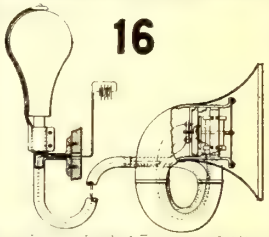


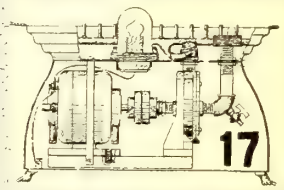


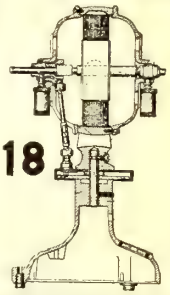


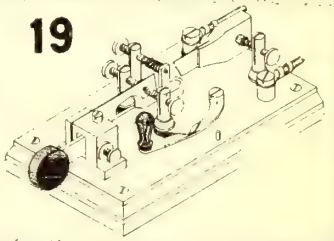












AMONG THE AMATEURS

AMATEUR RADIO STATION CONTEST.

Monthly Prize, $3.00.

This month's prize winner.

HENDRIX LABORATORY.

I am a regular reader of *The Electrical Experimenter,* and as I have made my wireless set what it is by reading this paper I would like to see a picture of my station in it. My aerial is 150 feet long, 105 feet above the ground at one end and 90 feet high at the other end. I have seven strands of solid copper wire No. 12 on 12-foot spreaders. The ground is a 12-foot galvanized iron pipe driven 11 feet into the ground.

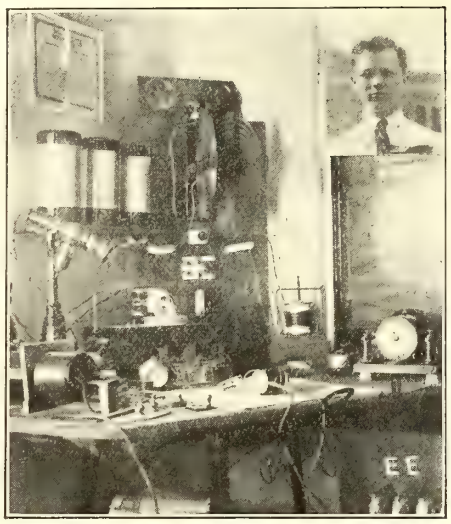
My receiving set is composed of loading coil, loose coupler which tunes to about 2,500 meters, a rotary variable condenser in the primary circuit of the loose coupler, and a tubular variable condenser in the secondary circuit. I have two pairs of 'phones, one pair of 3,000 ohms and one pair of 2,000 ohms; potentiometer for electrolytic detector; also E. I. Co. Radioson, Ferron, Turney crystaloi, galena and perikon detectors. These are arranged on a six-point switch. I have a fixed blocking condenser with switches for adjustment, and a fixed condenser with switch across 'phones. A buzzer test is also included in the set, which incorporates a common buzzer, an amplifier and battery and push-button. A single slide tuning coil is also shown in the picture, which, by means of

Mr. Hiram Hendrix Receiving Arlington Time Signals Via Radio.

a switch, may be thrown in as an extra loading coil.

Here is a list of a few of the stations which I receive from: N. A. A., Arlington, comes in very strong; N. A. R., Key West, comes in quite strong; I. W. C. O., Springfield, Ill., quite strong. I also get Tuckerton, Sayville and Colon sometimes on exceptionally good nights. *I would like to exchange photos of wireless sets with other amateurs.*

HIRAM HENDRIX.



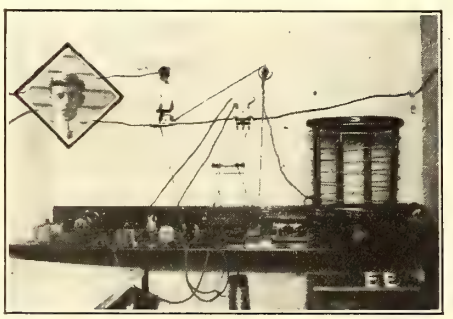
Wellsboro, Pa.

PHIL SCHMITT'S RADIO EQUIPMENT.

I am sending you a picture of my radio set. My transformer is ¼-K. V. A. I am using a quenched and rotary gap. The oscillation transformer is of Telefunken type. Almost all the instruments are my own make and style, made mostly from E. I. Co. goods. For an aerial I am using one wire about 500 feet long and 60 feet high. I am getting excellent results with it. The station is located in my bedroom, and the first and last thing when getting up or going to bed is to sit down and listen in or flash off a few "good mornings" or "good nights" to my radio chums. I have been a reader of *The Electrical Experimenter* ever since its first issue and it has been a great help for my experimental work.

PHIL SCHMITT.

New York City.



Phil Schmitt and His Excellent Wireless Equipment.

PARK SNYDERS RADIO STATION.

The transmitting set of my radio station consists of the following instruments: One-inch spark coil, wireless key, a large aluminum wire helix, two 1-quart Leyden jars and spark gap. The helix and the Leyden jars are home-made and the other instruments are factory-made.

My receiving set is composed of an Amco loose coupler, home-made loading coil, Brandes' 2,000 ohm head set, an E. I. Co. Universal mineral detector and a cat-whisker defector, a fixed condenser and a Murdock rotary variable condenser.

The aerial is 50 feet high at one end and 40 feet high at the other end, and is 85 feet long. It is supported at both ends by iron masts made of 1 and 2-inch pipes and is braced every 20 feet by three guy-wires. The aerial proper consists of four No. 14 aluminum wires, each 85 feet long and spaced 2 feet apart on 6-foot spreaders. These four wires are connected together at both ends. My lead-in is a No. 4 rubber insulated copper wire and is 20 feet long. This wire runs from the aerial to the

Park Snyder and His Wireless Transmitting and Receiving Set.

ground switch and from there a No. 14 copper wire runs to my instruments. I use two of the wires for sending and all four of them for receiving.

On the wall is seen my aerial switch and also a line switch. With this set I have no trouble in "talking" with other operators who live within a radius of 10 miles. I have had very good results in long distance receiving work and I hope to have better luck soon, as I am going to add another loose coupler and variable condenser to my set.

PARK SNYDER.

Connersville, Ind.

THE LEHIGH WIRELESS ASSOCIATION.

The Lehigh Wireless Association, with headquarters at Allentown, Pa., was organized Oct. 2, 1914. About a month ago the following officers were elected:

Earl Back, president; James Gardner, vice-president; Arthur Lentz, treasurer; Arthur C. Jacoby, secretary.

Almost all the members of the association have up-to-date transmitting and receiving sets and are also licensed operators. Meetings are held weekly at the home of the president.

The association has a 1-K.W. transmitting set, which can transmit about 100 miles, and messages have been received from NAR, NAU, NAW and WCC, and would like to communicate with other wireless associations. All communications are to be addressed to Arthur C. Jacoby, secretary, 517 Linden street, Allentown, Pa.

WIRELESS SET OF ARTHUR JACOBY.

Herewith is a flashlight photograph of my wireless station. Although I am not a

Arthur J. Jacoby and His Well Finished Radio Set.

subscriber I get the magazine every month in town. My aerial is 100 feet long, 70 feet high at one end and about 40 feet at the other end, composed of four strands of wire.

The station is equipped with a complete receiving and sending set. The receiving set consists of a loose coupler, two loading coils, three detectors, galena, perikon and crystaloi, one variable condenser, fixed condenser and a pair of 2,000-ohm 'phones.

The sending set consists of 1-inch spark coil, condenser, helix, spark gap and key, and can transmit about five miles. The station has a small switch-board with all the instruments wired to it.

The station has a receiving range of 1,000 to 1,500 miles day and night.

ARTHUR C. JACOBY.

Allentown, Pa.

ALBERT MEDAL TO MARCONI.

The Albert medal of the Royal Society of Arts, London, was recently presented to William Marconi. The medal was instituted in 1863, when the Prince Consort was president of the society. The medal is awarded annually for "distinguished merit in promoting arts, manufactures and commerce."

Phoney Patents

Under this heading we will publish hereafter electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore announce the grand opening of the

PHONEY PATENT OFFIZZ

For the relief of all suffering daffy inventors in this country as well as the entire universe.
We will revolutionize the Patent business immmediately and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of examiners to issue a Phoney Patent on your invention in a jiffy.

PHONEY PATENT OFFIZZ

ANANIAS GASBLOWER OF CHAUTOKA

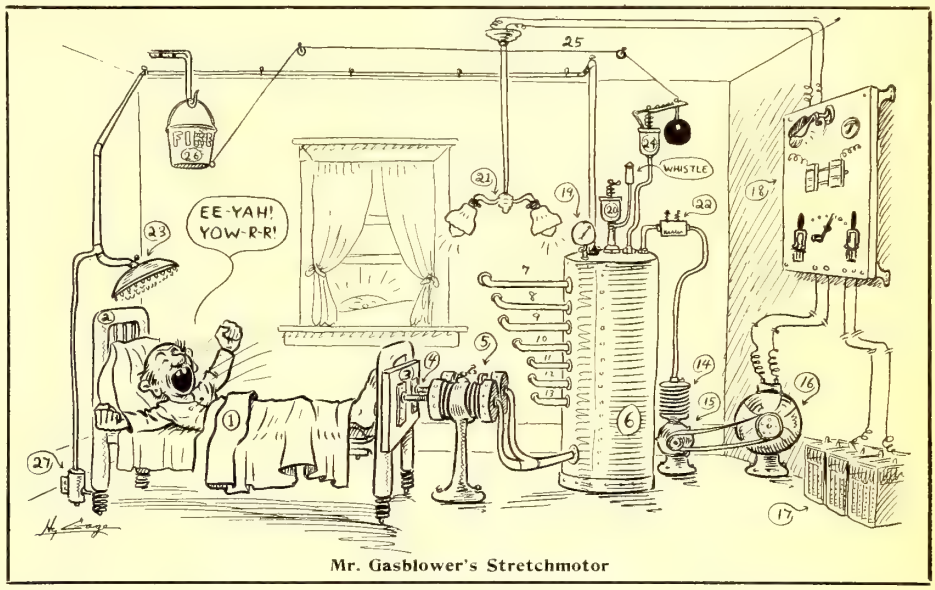
STRETCHMOTOR

No. 0009¼ **Potented June 63, 1915**

Specification of Phoney Patent
Application fired November 39th, 1769

TO ALL WHOM IT DOES NOT CONCERN:

Be it known that I, Ananias Gasblower, a resident of Chautoka, in the county of Ishkabibble, in the state of Wis., have invented a new and useful, revolutionizing means of conserving power, which since the beginning of the world has gone to waste.



The object of this invention is to provide a means of collecting and storing the tremendous amount of power expended when man stretches himself after awakening in the morning. Up to now this power has gone to waste, but my new invention which I term the Stretchmotor, will do away with all this. It has been estimated that a full grown man giving a healthy stretch produces an average pressure at the foot of his bed of about 120 lbs. Most individuals stretch themselves from 4 to 7 times in the morning, each stretch lasting about 4 seconds. This means that a total energy is developed that could lift a weight of from 480 to 840 lbs. about 2 feet above the floor—a tremendous power. Lazy people or those fond of stretching will even do better. My calculations show that if the entire stretching power of every citizen of a town of 100,000 people could be converted and stored of only one morning, the entire city could be lighted up with electricity for 4 days, 6 hours, 12 minutes and 19 seconds.

With this object in view my invention consists essentially of an individual, a morning, a bed, an air compressor, a dynamo, a storage battery.

In the drawings which accompany and form part of this specification I have illustrated in diagram several features which embody the subject of my invention, and how the stretchmotor is operated in practice.

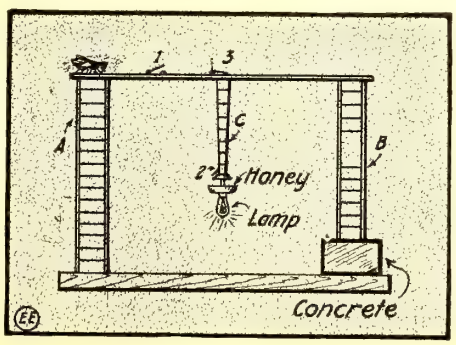
In the drawing (1) represents the individual, just awakening; (2) is the bed; (3) is the footboard; (4) are the connecting rods connecting the footboard with the piston of the air compressor (5); (6) is the compressed air tank in which the energy is stored; (7), (8), (9), (10), (11), (12) and (13) are pipes coming from the other bed-rooms of the house, each pipe being connected to a piston and a compressor, which in turn are attached to the other beds throughout the house. (14) Is the piston of the compressed air motor (15), which is belted to the dynamo (16), which in turn charges the storage battery (17); (18) is the switchboard and automatic cut-out; (19) is the air pressure gauge; (20) the safety valve. This safety valve has a whistle attached to it; thus if the members of the family generate too much energy the whistle will blow as a warning to all not to stretch themselves too long or too strongly. At (24) another valve is shown. This is a final emergency valve. It is technically called the Ultimatum valve. If the individual pays no heed to the sounding of the whistle and persists in stretching himself the pressure in the tank (6) may rise up to 12,000 lbs. per square inch. As soon as this happens the Ultimatum valve (24) opens, which in turn pulls down the string (25). This string runs over several pulleys to the water pail (26), which is upset thereby and its contents are poured over the individual (1), extinguishing him completely. (21) Are the electric lights, lighted from the storage battery (17). As soon as the pressure within the tank (6) reaches 6,000 lbs. per square inch, an automatic valve (22) opens and the compressed air flows in the piston (14), which operates the compressed air motor (15).

(23) Is a compressed air blast which starts automatically after the individual begins stretching. This air blast blows a strong blast of air in the individual's face, which is so disagreeable that he will get up and remain up. This discourages individuals from staying in bed once awake, and furthermore awakens them thoroughly. As soon as the occupant leaves the bed a spring (27) closes the airblast automatically.

Mr. Gasblower's Stretchmotor

In testimony whereof I have hereunto subscribed my name this 35th day of November, 1769.

ANANIAS GASBLOWER.



AN ELECTRIC FLY KILLER GUARANTEED TO WORK.

While there have been many electrical insect traps and annihilators perfected and patented, one of the most novel, perhaps, is described below by the aid of the sketch shown.

The inventor of this marvelous electrical "Fly Annihilator" has explained the principle of it as follows:

The fly is attracted to the device first by the odor of honey or molasses, which is placed in a small, inaccessible cup mounted over the incandescent lamp as indicated. The fly walks up the ladder "A" and along the footpath provided for his majesty at the top of the instrument.

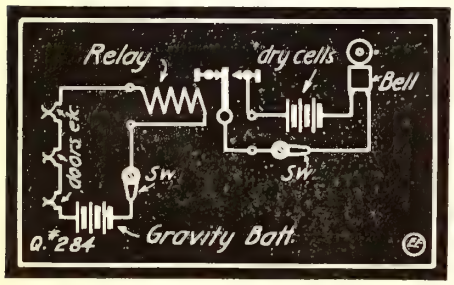
The illustration shows the fly walking toward an electrical switch "1," and when he passes over same in his quest for the honey the electric lamp is thereby switched on. He then proceeds to climb rapidly down the ladder "C" toward the honey, guided, of course, now by the illumination from the lamp.

When he reaches the trigger switch "2" the lamp is extinguished, and at the same time a small spring-actuated barrier "3" stands up vertically, thereby effectually cutting off his retreat.

The little fly now starts to walk back up the ladder "C," and when he arrives at the top he has but one alternative, and that is to walk along the footpath and down the ladder "B" to terra firma.

Sad to relate, there are about three steps missing in the ladder "B," and before he has time to "watch his step" he is precipitated violently onto the concrete block below and dashes his brains out.

QUESTION BOX



This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

CLOSED CIRCUIT BURGLAR ALARMS.

(284.) Leopold M.——, Brooklyn, N. Y., asks several electric burglar alarm questions:

A. 1. You will undoubtedly have to employ a closed circuit battery, such as the gravity cell, for your particular form of burglar alarm. Diagram is given showing how this is used with a relay, and if the wire in the main circuit is cut by an intruder at a window, for instance, then the

Closed Circuit Burglar Alarm.

battery current, of course, will be cut off from the relay and the armature of same will be released by its magnets; this allows the armature to drop back against the contact screw, as will be perceived, thus closing the alarm bell circuit.

The relay in this case should have a fairly high resistance of, say, 150 ohms' value; three to four gravity or crow-foot cells will be all right for the work. Ordinary dry cells can, of course, be used in the local (open) alarm bell circuit to the number of three or four for a medium-size bell, etc.

STATUS OF PATENTED ARTICLES.

(285.) William Foerste, Pelham Manor, N. Y., inquires as to the status of patents on wireless devices as related to manufacturing, etc.:

A. 1. You can manufacture or sell wireless and electrical apparatus as you mention without obtaining any license, except instruments which are patented and already sold under a license, etc. In this case you will, of course, have to take up the matter with the owners of the patent or the company who already builds the instrument. Otherwise you are liable to get yourself into no end of trouble. We may say in this direction that from many cases which have been settled in the past of such a character it has been the rule that invariably the party making apparatus without license rights from the patent owners have had to pay all the patent royalty accruing on the total sales of such instruments for the total period during which they were manufactured prior to court action.

A. 2. We are not familiar with the details of the wireless system utilized by Mr. Eugene Dynner, of Guttenberg, N. J., but you can, of course, write to him and he will be undoubtedly glad to give information you desire.

TRANS-ATLANTIC RADIO PLANTS.

(286.) Donald Rockwell, Wellsboro, Pa., wants to know why the powerful radio station at Arlington, Va., was not shown on the map of Transatlantic radio stations published in the March *Electrical Experimenter*:

A. 1. The reason why the radio station at Arlington, Va., was not shown in the recent Transatlantic Radio Map was due to the fact that Arlington is not considered, in the ordinary sense, a Transatlantic wireless station. While the signals from Arlington have been heard across the ocean it does not do this work regularly, as is the case with the German stations at Tuckerton, N. J., and Sayville, L. I.

We have no data on the operating range of the radio station at Colon, Panama, but it has been heard in New York City a great number of times by experimental wireless stations.

Want to Swap?

If you have anything to buy, sell or exchange and want to make sure of doing it quickly and at an insignificant cost advertise in the

Scientific Exchange Columns
OF
The Electrical Experimenter

You will find advertised in these columns:

Photographic supplies, Phonographs, Wireless Apparatus, Electrical goods, Bicycles, Motorcycles, Rifles, Gasoline Engines, Microscopes, Books, Skates, Typewriters, Etc.

The owners of these things wish to ***"swap"*** them for **something else, something which you may have.**

One cent per word (name and address to be counted) minimum space 3 lines. Average 7 words agate to the line. *Remittance must accompany all orders.*

The Classified Columns of the ELECTRICAL EXPERIMENTER GET RESULTS

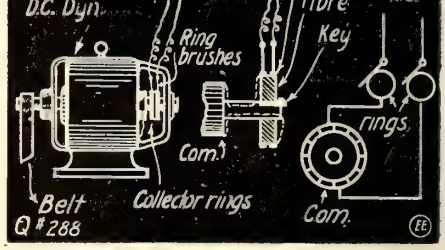
More than 35,000 Electrical Experimenters will see your ad.

STORAGE BATTERY TROUBLE.

(287.) Fred Taylor, Norfolk, Conn., says his storage battery will not hold a charge for any length of time and wants advice on his probable trouble:

A. 1. We do not know what your battery trouble may be, but possibly the cells need washing out thoroughly, as there may be some collection of sediment on the bottom of the jars. In this case the electrolyte should be poured out of the jars and they can then be filled with clean water and flushed out several times, till the water flows clean. The electrolyte should then be strained through a piece of fine cloth and replaced in the battery. Add distilled water to bring its specific gravity to proper point if high in density. Also add distilled water only in filling up cells to cover plates when exposed by evaporation of water in electrolyte.

In some cases the battery plates become covered with a white coating known as sulphate. If you are having trouble of this character the following directions for sulphation treatment will probably be of service.



For sulphation treatment charge the battery as rapidly as it is possible to send current into it without overheating. The resistance being greatly increased by the effect of the sulphate, the cell will become hot when charging. Use a thermometer in the electrolyte to test the temperature and maintain the current at such a value that the temperature of the cell does not exceed 110 degrees F. Continue this charge until the plates begin to gas freely, then reduce the rate of charge to the eight-hour rate and continue this until the plates again begin giving off gas. The rate of charge should then be reduced to half the eight-hour rate and continued until further gassing again occurs. The cell should then be partly discharged and the treatment repeated. This cycle of operation may have to be carried on for some time, but should be continued until the negative plates show at least 0.10 volts between a cadmium electrode and the negative plate, the cadmium being positive to the negative.

ALTERNATING CURRENT FROM D. C. DYNAMO.

(288) G. L. La P., Iowa, wishes to use some form of mechanical interrupter on his 110-volt D. C. dynamo circuit (3 K.W.) instead of an electrolytic interrupter, for operating his wireless set.

A. 1. We do not know anything to suggest in the matter of operating a couple of ½ K.W. transformer coils on 110-volt D. C. circuit with some form of mechanical interrupter. We would further advise that it is not generally satisfactory to use a mechanical interrupter for 110-volt circuits in the way you propose.

A suggestion for you in this direction,

A. C. From D. C. Dynamo.

and we believe you would find it the best of all, is cited below; besides, this would enable you to use a rotary spark gap of the synchronous type.

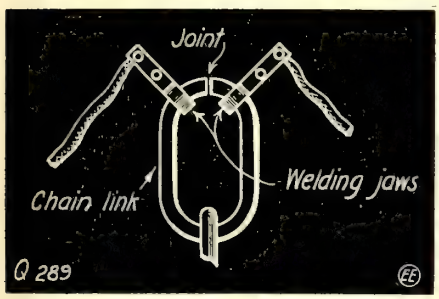
The sketch depicts this suggestion in detail, and it simply consists of placing two brass collectors on your dynamo shaft, with two brushes placed in contact with the rings, from which to take alternating current. These two rings are connected to

diametrically opposite commutator segments, as the diagram shows, and you can in this way obtain about 75 to 80 volts alternating current, if your direct-current dynamo rating is 110 volts.

The dynamo is driven in the regular way by belt, and also you can arrange your rotary spark-gap disc or arm on the end of the shaft by extending same, if necessary, and you will then have a synchronous spark-gap outfit similar to the Fessenden style commercial sets.

With this arrangement you may use a closed-core wireless-type transformer, etc., or you might make up an open-core transformer from three ½-K.W. transformer coils.

Instead of the rotary gap you can also very readily employ a quenched spark gap. We presume your D. C. dynamo is a two-pole machine, and you will then get in the neighborhood of 60 cycles frequency A. C. with the armature running at 3,600 R. P. M.



The commutator is left the same as it now is, and if you desire to take A. C. only from the machine, and if there is not sufficient room to place the collector rings and their fiber drum between the commutator and the bearings, you might arrange to mount this drum and rings on top of the commutator. A local machinist can do this for you at small expense.

Another scheme in this direction is to mount the collector-ring drum on the outer end of the shaft beyond the bearing, and to bring the two wires to the collector rings from the commutator through a small hole bored through the center of the armature shaft, as the sketch shows.

ELECTRIC "CHAIN" WELDING.

(289) John Burkett, Madoc, Ont., Can., asks several questions.

A. 1. There have been no recent developments in the use of iron cores for high-frequency tuning coils, etc., and the reason why they are not used for this purpose is due to the fact that the iron tends to lag behind the magnetizing current in its magnetic reversals of polarity, etc. This creates a very bad power-factor and occasions, therefore, considerable losses in the coil.

How Chain Links Are Welded Electrically.

A. 2. Answering your second question regarding the welding of wire fencing and chain links, etc., by electricity, would say that this takes place on the basis that the electric current will always, of course, take the shortest or lowest-resistance path through a conductor, and you can thus see that by proper arrangement of the welding-machine jaws and contacts the shortest path for the current will, for instance, in the case of a chain link be through the joint in the link, as the sketch herewith shows.

Special arrangements of the contact jaws of the welding machine are made use of in electric fence welding.

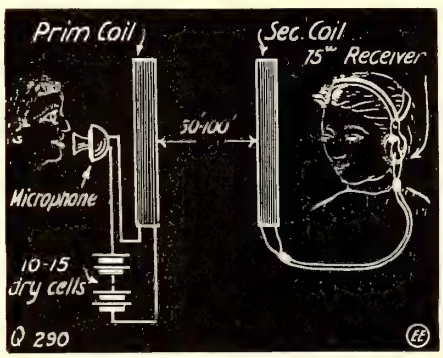
Present Occupation _____



The theory of this work is that the electric current will always, as aforesaid, take the path of least resistance through a conductor, and as the greatest amount of current will thus pass through the shortest part of the chain link, for example, it is patent that this part of the circuit will become the hottest and will thus be welded electrically, as the heating effect in a circuit is due to the value of the current in amperes, squared, multiplied by the resistance in the circuit in ohms.

INDUCTIVE SYSTEM RADIOPHONE.

(290) Edward L. Jewett, Sullivan, N. H., inquires about building an inductive-type wireless telephone using two large coils of wires acting on each other by electro-magnetic induction.

A. 1. Regarding the inductive type of wireless telephone, would say that of course the large the coils are made, other things being equal, the better this arrangement will talk. It is, however, only adapted, generally speaking, to short-range demonstration work and the like.

The wire you mention for the coils is all right and it is well to make the receiving coil of finer wire, as suggested, as the receivers of course have a higher resistance and cannot be benefited by the heavy

Inductive Type Wireless Telephone.

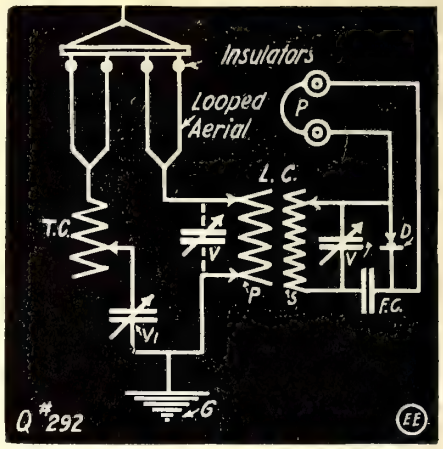
current generated in a coil of large-size wire.

You are correct in assuming that it is the ampere-turns in the coils which count most; but of course the various parts of the circuits should be properly related to each other in any case. This matter is fully discussed in H. Gernsback's 25-cent book, "The Wireless Telephone," supplied by our book department.

RADIO QUESTIONS.

(291) L. B. Wilcox, Angola, Ind., asks us several wireless questions on spark gaps, etc.

A. 1. The rotary spark gap you mention should be all right. To properly break the detector circuit with break-in system, as you mention, the detector should be short-circuited by means of automatic switch or by extra contacts on the transmitting key, whenever the transmitting set is excited.



We do not recommend an iron-filings refer you to the February, 1915, *Electrical Experimenter*, wherein you will find curves given for reading wave lengths direct.

We do not recommend an iron-fillings core for your transformer, but a sheet-iron or an iron-wire one will prove superior, we believe.

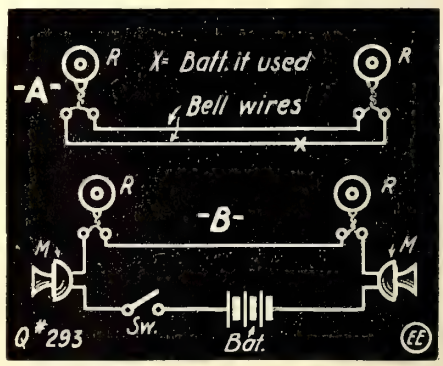
The wireless station at Key West, Fla., sends time signals and weather reports via radio at noon, Eastern time.

VARIABLE CONDENSER CONNECTION.

(292) Austin Hewes, Crete, Ill., wants to know how to hook up a variable condenser to his radio receiving set, and he

Looped Aerial Connections.

also complains of severe static signals in his 'phones.



A. 1. The variable condenser may be connected across the secondary of the loose coupler. The diagram here shown has been used by several of the commercial radio companies and you will find this arrangement will enable you to tune out a great deal of static, etc., through the static tuning loop, comprising a tuning coil T.C. and variable condenser V_1, as observed.

SERIES TELEPHONE.

(293) H. J. Brown, Cleveland, O., writes us regarding the use of two 75-ohm telephone receivers on a bell circuit for telephone purposes.

A. 1. We give you herewith diagram (at "A") showing you how to use a couple of telephone receivers of the 75-ohm type for carrying on conversation over a bell wire circuit, etc.

It sometimes improves matters a great deal to connect a couple of dry batteries in the circuit, and you will vastly improve the efficiency of this arrangement if you connect in a couple of regular microphones

Series Telephone Hook-Up.

"M." You will then have what regularly constitutes a series telephone circuit, capable of talking over a number of miles. The battery should be cut out when through talking by a switch.

Note: On July 1 the subscription price of THE ELECTRICAL EXPERIMENTER goes to $1.00. Don't fail to take advantage of the present low rate. See page 95.

PATENT ADVICE

Edited by H. GERNSBACK

Shall He Patent Detector?

(1) Alfred Smith, Waukegon, Wis., submits a drawing and plans of a wireless detector stand; he wishes to know if we advise him to apply for a patent on the instrument.

(A.) As a general rule would-be inventors of detector stands could save a lot of money and energy by not trying to patent such devices. While we do not say that a patent could not be obtained on the detector stand described by our correspondent, we certainly will say that such a patent would assuredly not be of much commercial value.

It should always be borne in mind that it is a rather simple matter to obtain a patent, but it is another thing to exploit the same patent commercially. After all, a patent is not obtained except to exploit it commercially; it is no honor to have a long list of patents that lay idle and on which much money has been expended, if such patents are not utilized commercially. In the case of the detector stand of our correspondent the article no doubt has some original points, but none of them is novel enough or strong enough that it could not be evaded by a clever constructor. There have been so many detector stands described in the current literature that it is almost impossible to find any kind of a detector movement that is novel and that could not be easily modified by anyone.

We strongly advise would-be inventors not to spend money in trying to patent detector stands or similar appliances.

"Patent Applied For."

(2) Henry Schneider, Milwaukee, Wis., asks us if he can market an article on which he has applied for patent some time ago, but on which the patent has not as yet been granted.

(A.) We strongly advise against marketing any article which has not been patented. The mere reason for applying patent does not mean anything whatsoever and affords no protection for the following reasons:

If your article, on which you have patent applied for is put on the market, and if a competitor should market a similar article it will be impossible for you to bring any action against him because you have no patent. Also, if your competitor wishes to do so he can file a patent application covering the identical article. This means that there would be in the Patent Office immediately what is technically called an *"Interference."* The Patent Office will then throw the two applications out and will let the two contestants fight the case out between themselves. This usually is quite an expensive procedure and unless the invention is quite valuable it is not feasible for the two contestants to fight it out in court. Most of the time the patent case is dropped all together, while the original inventor must either go on fighting his opponent or else allow him to manufacture the same article. Another feature is that it is impossible to foretell how soon a patent will issue even if no "Interference" is recorded at the Patent Office; your patent may not *issue* for years.

In the meanwhile a competitor could establish a growing business and while you might collect back royalties from him afterwards, if your patent is finally proven valid, it invariably means expensive law suits. Besides, if your competitor has once obtained a start it is usually very hard to stop him.

For these reasons we would advise all inventors to be very cautious and not to market an article until the patent has been granted by the Government.

Once you can show that the patent has been allowed and your label or literature is sent out with your merchandise calling attention to the patent, most people, unless they feel sure of their grounds, will not attempt to manufacture the same article. This is where a patent usually protects.

Is Switch Patentable?

(3) Alfred B. Duck, Richmond, Va., has sent in a rough sketch of a switch and wishes to know if we advise him to patent the invention.

(A.) The sketch is so rough and incomplete that it is impossible to tell just how this is supposed to work; also, the description is not clear enough for us to form an opinion of the function of the supposed invention. We would ask our correspondent to send in a better sketch and a better description.

We publish this merely as a request to inventors to make their sketches as clear as possible when sending drawings to this department. This will do away with a great deal of delay and will make it possible for this department to publish the answer at once. It should be borne in mind that this department does not answer patent questions by mail, but publishes all information of this kind for the benefit of all readers.

Search for Patentability.

(4) Fred P. Opp, Cleveland, O., asks us how much it costs to have an attorney make a search in the Patent Office in order to find out whether an invention is patentable.

(A.) There is no fixed charge for work of this kind to our knowledge. Some attorneys do not make any charge whatsoever if they have an order to patent an invention. Others charge small sums from a few dollars upwards, all depending upon how much work has to be expended.

At the Patent Office most inventions are filed in classes, thus, for instance, there is a class for wireless detectors, another class for non-refillable bottles, another class for electric lamps, etc. It is easy to understand that if a patent attorney must consult several thousand previous patents the charge will be very much higher than in the case of a new art; as, for instance, a wireless detector, of which not over 200 have been patented. For that reason it will be seen that it is impossible for anyone to say how much the fee will be, and the best thing in this case is always to consult a patent attorney and find out. Such information is gladly given by all attorneys.

Patenting a Hook-up.

(5) William B. Nelke, San Francisco, Cal., has sent in a blue print showing the hook-up or diagram for a wireless telephone and wishes to know if we think that he can obtain a patent on this invention.

(A.) Nothing new is seen in the hook-up which our correspondent has submitted

Our New Book Catalog

will be off the press on

July 15th, 1915

This catalog is particularly complete and up-to-date. Every book is illustrated and exactly described as to number of pages, size, bindings, illustrations, etc.

This valuable catalog will be sent on receipt of 2 cents to cover postage.

"BOOK DEPARTMENT,"
Experimenter Pub. Co., Inc.
233 Fulton St., New York

17 FREE SCHOLARSHIPS

ARE NOW BEING OFFERED

LEARN TELEGRAPHY and WIRELESS FREE

The confused condition of the commercial world has created a vast increase in the use of wire and radio. We believe that students who start now will reap the advantages of great opportunity created by the war.

This contest requires no study or special knowledge; anyone with mind enough to learn telegraphy competes on an even basis. Send us 25c (now) for necessary contest sheets, entry blanks, etc., and our book on "Telegraphy and Wireless as an Occupation." You'll enjoy the entertainment this novel contest affords.

BOSTON SCHOOL OF TELEGRAPHY
18 Boylston St., Boston, Mass.

New York Electrical School

THE only school in the world devoted to teaching every angle of Electrical Industry by "actual practice." All ages from sixteen to sixty enter this school on the same level and are shown "how" and "why" in a manner that ensures absolute success.

No preparation needed to become a "learner" in this school. You can start this course any day of any week throughout the whole year.

We particularly desire to have it known that all VISITORS are heartily welcomed at this unique training institution.

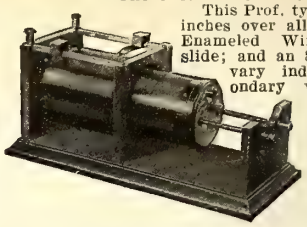
to us. While the arrangement of the choke coils and the connection of the microphone differs somewhat from existing connections, we do not think it would be a wise thing to attempt patenting this hook-up, as we are quite positive that no patent could possibly be obtained.

We advise against attempting to patent any kind of a hook-up because it is one of the very hardest things to obtain a good patent on mere connections or circuits. Unless some novel instrument or other features are made a part of the patent a circuit alone will not be of much value, as most anyone could use such a circuit anyway, privately or otherwise, and it would be almost impossible for the patentee to know whether anyone was infringing on his patent or not. There are, of course, a good many circuits or, as they are usually termed, systems patented, but we doubt if there are many of much commercial value.

BARON MÜNCHHAUSEN'S NEW SCIENTIFIC ADVENTURES.

(*Continued from page* 90.)



"tasted" exactly like sulphuric acid fumes, similar to the fumes given off by a storage battery when it is "gassing." After a few minutes we became accustomed to the sharp atmosphere, but we found it very hard to breathe at first. Then our bewildered senses became conscious of the fact that we felt a warm glow all over our bodies and in a few minutes we became exhilarated as if intoxicated. For three-quarters of an hour we were actually drunk, and it was exceedingly hard to think clearly during that time. This effect, however, wore off too, and at the end of the second hour we could breathe fairly easy, although our lungs pained terribly and we spat blood at frequent intervals.

An analysis of the moon's atmosphere made by us shortly thereafter explained our odd behavior and the strange effects of the new air upon us. To begin with, the moon's air is very thin, only about 1-16th the density of the earth's atmosphere. Where the earth's atmosphere is composed of about 79 per cent. nitrogen and 21 per cent. oxygen, the moon's atmosphere contains 26 per cent. carbon dioxide, 24 per cent. nitrogen and 50 per cent. oxygen. The carbon dioxide caused us to cough so violently while the invigorating oxygen in its prepondering proportion in the air intoxicated us. If the moon's air were as dense as that on the earth I doubt if a human being raised and brought up on earth could survive. But by being 1-16th as dense as the terrestrial atmosphere, together with the fact that oxygen is very beneficial to the respiration, it becomes possible to endure the moon's thin air comfortably. It is interesting to note that if vitally necessary human nature will adapt itself successfully to even the most difficult surroundings. This we found out speedily; within 48 hours we not only breathed with comfort and wholly without pain, but we found the new air so enjoyable as well as invigorating that we looked forward with dread of again inhaling the stuffy terrestrial atmosphere. After one grows accustomed to the singular smell of the moon's air one comes to cherish it. It acts like a powerful tonic, the oxygen no doubt being largely responsible for this.

At first, of course, we found it very difficult to walk on the moon's surface, for the reason that we weighed so little now. The earth being 50 times as large in bulk and 1.66 times denser than the moon, it naturally attracts all bodies with much greater force than does the moon.

INDUCTIVE TUNER

There Is None Like It.

This Prof. type Tuner, 7x7x15 inches over all, is wound with Enameled Wire, has double slide; and an 8-point switch to vary inductance of secondary winding. Price, $7.00.

Parts of this Tuner, unassembled; wood work stained, tubes wound, taps made, etc., $5.50.

Our latest catalogue has 64 pages, and over 100 illustrations; and deals entirely with Wireless Telegraph Apparatus.

You should note our Rotary Spark Gaps. Also parts of same sold separately, if desired. Everything else equally interesting, especially prices. Send 5 cents in stamps for this large new catalogue B-B-24. Positively none sent otherwise.

SEND FOR COPY OF OUR

New Wireless Manual No.9

Its pages contain simple formulas for calculating the natural period of an antenna; capacity of a receiving or transmitting condenser; spark frequency of rotary spark gaps; tables for calculating the correct amount of wire for the construction of magnets and tuning coils; tables for ascertaining the spark lengths of different voltages; the Federal regulations regarding the restrictions of wave lengths for amateur stations; instructions for the installation, maintenance and operation of wireless stations; directions for learning the code, workable diagrams and a complete list of up-to-date wireless instruments and accessories, together with other features of interest to the amateur or professional wireless enthusiast.

Containing as it does a fund of valuable information not generally contained in a catalog it approaches nearer a text book in the fascinating field of wireless telegraphy.

It is printed on good stock with a heavy paper cover in two colors. No expense has been spared to make it accurate and reliable.

We make a charge of 10 cents for it which amount will be allowed on an order amounting to $1.00 or more.

Send for our Pocket Catalog W 28

It contains over 240 pages, with over 1,000 illustrations, describing in plain, clear language all about Bells, Push Buttons, Batteries, Telephone and Telegraph Material, Electric Toys, Burglar and Fire Alarm Contrivances, Electric Call Bells, Electric Alarm Clocks, Electrical Batteries, Motor Boat Horns, Electrically Heated Apparatus, Battery Connectors, Switches, Battery Gauges, Wireless Telegraph Instruments, Ignition Supplies, Etc.

CRYSTALOI

The New Permanent Wireless Detector

NEW NEW

EXTREME LONG DISTANCE

MICROMETRIC ADJUSTMENT

This WONDERFUL LITTLE DETECTOR is the height of Mechanical and Electrical achievement and will simply astonish you in its performances.

IT WILL NOT BURN OUT OR GO DEAD and will last indefinitely. All elements are sealed in the little cyinder which is revolved to secure finest adjustment. The "Crystaloi" is positively the **most sensitive** and thoroughly practical detector ever designed. It is not a make-shift. It is a precision instrument in every sense of the word, and is beautifully finished.

EACH "CRYSTALOI" is tested for extreme long distance at our station, which insures the one you get being absolutely perfect or money refunded. WRITE TO-DAY for full information. Immediate delivery.

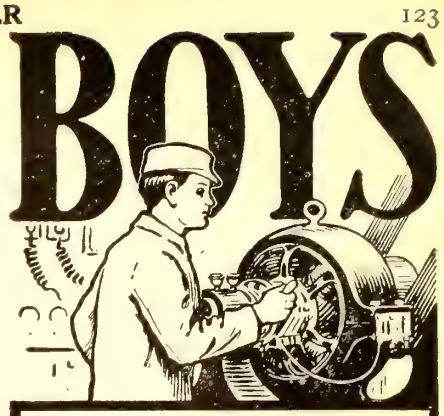
fitting you for positions paying good salaries with wonderful chance to travel the world over. It's the most interesting profession known and the demand for skilled operators is increasing Send for catalog giving facts.

NATIONAL RADIO SCHOOL, 1403 U St. Washington, D. C.

Thus a stone weighing one pound on earth weighs but 0.167 lb. on the moon, which is just one-sixth of the weight the stone has on earth. My own weight on earth being 170 lbs. it naturally follows that I could weigh but 28 lbs. on the moon. Buster, who weighs some 10 lbs. on earth, weighs but 1½ lbs. on the moon. He found this out soon when he began to jump about. On earth he would not have jumped higher than about 4 feet. On the moon his 1½ lbs. carried him six times higher, for he expended as much muscular energy in his jump as he was accustomed to do on earth. Consequently he went up some 24 feet into the air. This frightened him considerably, for he had never jumped so high in all his life. As in the *"Interstellar,"* he became more careful thereafter and limited his jumps to 10 or 15 feet in height.



Flitternix, as well as myself, amused ourselves in a jumping contest for some time and it was astonishing to us how high we could jump. Twenty-five to 30 feet was easy of accomplishment, and we did not come down hard either, for we weighed so little. One thing, however, we found out speedily. The moon's atmosphere even at the little elevation of 30 feet becomes so thin that it is impossible to breathe. For that reason we discontinued our high jumps soon and preferred long horizontal jumps after that. Subsequently we established the following facts:

The only atmosphere in which any kind of living creatures could exist extended but 20 feet above the surface of the moon. Sixty feet above the moon there was no trace of atmosphere. Here the vacuum of space begins. On earth, it will be noted, no atmosphere exists beyond 35 miles above sea level. Thus we found it impossible to scale the lunar mountains or even a low hill.

There being so little atmosphere on the moon, no clouds whatsoever, and but very little wind, it follows that the temperature of the moon's surface must be rather comfortable. We measured 78° Fahrenheit in the shade of the *"Interstellar."* Nor did this summer heat subdue during the long day of nearly two weeks. (The length of the day on the moon is almost two weeks, the length of the night being of the same duration.) This intense sunlight also made it impossible to walk about without some form of protection, but as we had brought our tropical sunshades along we were but little troubled on our long tramps, despite the heat. Without this precaution our hands and face blistered rapidly, due no doubt to the effect of the sun's ultra-violet rays through such a thin atmosphere, which offered but little protection.

After several hours immediately following our landing we concluded to leave the desert in order to investigate the nearest chain of mountains some 60 miles distant. Re-entering the *"Interstellar"* we started our tractor machinery and the big globe began to roll on its wide landing belt over the hot sands of the moon at a comfortable speed. In a few hours we came to a dead stop in the shade of an enormous mountain rising some 16,000 feet above the surface of the moon. No vegetation or any sort of life could be perceived anywhere, but curious marks on the ground convinced us that there must be indeed some form of life on the earth's satellite.

Arming ourselves with our large caliber guns we set out to follow the tracks. Buster, who ran ahead of us with his nose to the ground, had become excited and within a ten minutes' walk we entered an immense canyon with almost perpendicular walls several thousand feet high. This canyon was nearly closed at the top and

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large —promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

it was probable that the sun never reached the bottom. There was but little light and we had to advance cautiously, guided by Buster.

The temperature was rather comfortable, about 50° Fahrenheit, as our subsequent investigation proved.

As we walked on, the canyon seemed to become lighter, but we soon observed that it was not sunlight. The color of the light was of a pale green. We were very much puzzled at this and not a little excited, so we pressed on forward. We finally rounded a projecting corner and beheld a sight such as no humans had ever seen before.

The canyon, which by this time had become entirely closed at the top, suddenly widened out into a colossal cave of immense proportions. We found out later that the cave was roughly 12 miles in length and 8 miles in breadth. Although entirely closed at the top it was almost as light as day inside, the light, however, being of a vivid green. Almost the entire bottom of the cave was taken up with a lake and the light came from the lake itself. Within a few minutes we had reached the edge of the water and we saw immediately why the lake gave forth such a strong light.

We stood fascinated for some time at the sight which presented itself to our eyes. The lake was crowded as far as the eye could reach with a sort of eel fish —*and each fish was luminous.*

You have, of course, seen the common firefly during a hot summer evening. Take your firefly, extend it about four feet to the size of an eel, put it under a clear limpid water, and you have a good description of our lunar luminous fishes.

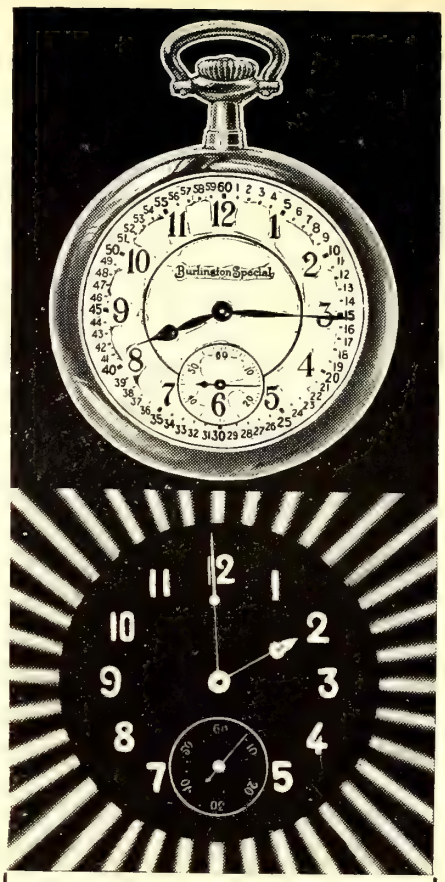
The sight of these strongly illuminated eels darting back and forward under the water with lightning speed is magnificent; it offers a wonderful spectacle. You can follow each fish to a considerable depth, for the light which they emit is very powerful. We found out that each fish produces some 60 candlepower of light. Here at last we are face to face with an exceedingly practical application of "cold" light, which our terrestrial scientists have been searching for for decades. We also observed that the fishes are luminous only while in motion. As soon as they stop swimming the light vanishes instantly. We have since observed that the light is produced by the friction of the fish's body against the water. Flitternix is not sure as yet whether the action is electric or chemical.

We marveled how nature always finds out a way to favor life, even under the most difficult surroundings. As life was manifestly not possible on the moon's surface on account of the blistering heat (and the extreme cold following) nature promptly produced it *under* the surface. As the higher forms of life require light for their existence and as there was no light under the moon's surface, nature saw to it that its life carriers were equipped with light themselves!

We were naturally overjoyed at our discovery. We knew now that there was at least water on the moon, despite all our scientists' theories. Buster was the first to try it and after a few cautious licks he decided that it was really water. We followed suit and immediately noticed that the water was slightly tart in taste, which, however, made it an excellent thirst quencher.

We discovered later that all of the moon's subterranean waters tasted alike, the tartness undoubtedly being produced by the ever-occurring sulphur which seems to abound on the moon.

We found it was comparatively easy to catch one of the luminous fishes, which was almost 4 feet long, and after killing it we decided to take it along to test its edibility. During the next few hours we also killed several luminous turtles of enormous size. As we did not see any other living creatures on the shores of the lake we decided that it must have been one of these turtles whose footprints we had seen outside of the canyon.



A survey of the cave showed that its southern wall was composed almost entirely of some form of coal similar to our terrestrial anthracite. We knew now that we were in no danger of starving. We had the water from the lake, meat from the fishes, as well as the turtle, and fire from the coal. We naturally felt highly elated, so Flitternix as well as myself decided to extend our visit to the moon as long as practical in order to fully investigate this newest world.

During the next few days (by this I mean a day of 24 hours' duration) we explored the entire cave and we came across many queer animals, mostly of the turtle type. We found few hairy or feathered types and nothing that approached even distantly the human form, as, for instance, the monkey type of our earth. We found that there was quite a little vegetation inside of the cave, mostly of the fungus type; there were also low shrubs and some dwarf forms of a peculiar bread tree. This bread tree is very similar in many respects to the terrestrial bread tree (*Artocarpus incisa*) as grown in some of the Pacific Ocean islands. We found its fruit, after baking it, highly nutritious as well as exceedingly tasty. The turtle meat was excellent and the fishes tasted somewhat like eels, with a fresh-water trout flavor. We found many varieties of mushrooms, some of enormous size and mostly edible. There was, furthermore, an abundance of various curious nut bushes and, with a few exceptions, all were very tasty.

You see we do not starve on the moon, even if it does look dead through a telescope. On the contrary, we are well provided for and could extend our stay indefinitely if we were so inclined. As a matter of fact we are in no hurry just now to return to mother earth, we like it so exceedingly well here.

We discovered soon that there were thousands of caves such as the one which we first discovered scattered all over the moon. These caves are all much the same, all illuminated, by means of their luminous animals. The caves vary, of course, much in size as well as in shape; some of them are hundreds and some even tens of thousands of feet below the surface of the moon. This is quite natural. The moon is a cold world unlike the earth, which is still in a molten state in its interior. The further you descend in the moon's bowels the colder it gets, but the atmosphere becomes denser also. Equipped with electric lanterns, we visited a cave several hundred feet below the moon's surface. The cold was intense, and we saw no living being of any sort, nor any plant life. What had been water once, myriads of years ago, was ice now, frozen down to the bottom. The sight was so desolate and so depressing that we hurried back to the surface as soon as our investigation was completed. We decided not to visit any more caves except those located near the surface of the moon, where the solar heat still could make itself felt.

During the next few days we found immense deposits of various metals, such as platinum, gold, copper as well as iron ore. There seems to be an abundance of these metals on the moon. We also found a curious metal (or it may be an alloy) which melts at a temperature as low as that of tin, but is as hard and flexible as steel.

U. S. PATENT OFFICE 2388E

We named it *Busterium* in honor of Buster, my fox terrier, who was the first terrestrial being to land on the moon.

But now, my dear Alier, I must terminate our chat for this evening. This is moving day for us. The sun is chasing us rapidly and Flitternix says we have only three hours before the *shadow* overtakes us."

"I do not quite follow you, my dear Münchausen; won't you be a little more explicit, please?"

"Certainly, my boy. You know that the moon revolves on her axis once in about 27 days. Her term of daylight must therefore be the half of 27 days, or nearly two weeks, and her night must consequently be of the same length.

"At the present we are somewhat in the neighborhood of the moon's equator. Within a few hours the spot on which I sit will be in the dark—it will be night—the beginning of the lunar two weeks' night. Already the sun is low in the heavens. As the temperature will fall below zero as soon as night sets in, and as we do not cherish to be frozen we have no other choice but to move our present position. We will, therefore, break up our camp shortly and will board the "*Interstellar*" once more. A few hours' ride will bring us to the other side of the moon, where it is now morning. Once we reach that spot we can make camp again for two weeks, the duration of the lunar day.

"Well, I must hurry, my dear boy; anyhow, it is one o'clock for you now and I have an idea that your bed is calling you. Therefore, *au revoir* till next time."

Keee-ee-ee-ee, Zeee-ee-ee-ee-ee. Zeee-eee-ee-eee é é é é é eeh-blob-blobb-flum-, and he was gone. The ether was quiet once more.

ELECTRICITY, THE POWER BEHIND THE SUBMARINE BOAT.

(*Continued from page* 105.)

base on board a German warship or a land station.

The general lay-out of the electrical equipment on board the submarines, and particularly the storage battery unit, is such that when cruising, or when lying to, the oil engine can be used to drive the dynamo by suitable throw-over mechanical gear and the dynamo then charges the storage battery so the vessel will be ready for the next dive under water.

The storage battery supplies electric current for a large number of different apparatus on board, including several electric motors for driving water tank and submersion pumps; also the current for operating electric heaters placed about the walls of the submarine, electric lights, the radio transmitting set, compressed air pump, small ¼-h.p. motor for turning the sighting periscope, through which the commanding officer obtains his view of warships, etc., on the surface of the sea, as the illustration shows, et cetera.

Also other uses of the electric current include that for heating the stoves or ranges for cooking the meals of the crew, electrical triggers or release mechanisms for discharging the torpedoes through the torpedo tubes, and which are propelled out of the tube by compressed air from an air storage tank in most cases. Also a small but powerful electric searchlight is provided on the upper deck of the submarine, which can be used when she is cruising on the surface, and duplicate installations are made; on the upper deck as well as on the inside central control deck where the commanding officer stands

KENNEY INK FONT 50c

Most practical ink-well made. Ink suspended by vacuum. No sludge forms. No dust nor dirt. Pen will not soil. Base and body handsomely nickel-plated. Heavy glass container.

Worth $1.00—**Price 50c. postpaid. Double font for red and black ink—$1.00. Agents Wanted.**

A useful gift. A necessity for dining room, bedroom, bathroom, kitchen.

LAVA HEATER
Patented, Trade Mark Reg.

Tungsten lamps give about three times as much light for the same current cost as carbon lamps.

ACCEPT THIS BOOK FREE
IT'S INVALUABLE YET CAN'T BE BOUGHT

Just as you will receive it, cloth bound, size 7 x 10¼ ins., 160 pages, 20 lessons, 350 illus., 30 tables, with every bit of information on Wireless you can possibly want, besides valuable information on Electricity, Magnetism and Theory of them **—and it's FREE as explained.**

Will you take a 20 lesson Wireless Course absolutely FREE—even postage charge prepaid?

A course that tells you everything you can possibly want to know about "Wireless" starting off in Lesson No. 1 by explaining the Principles of Electricity. The Second and Third Lessons are devoted to magnetism, motors; generators and wiring. And then, by simple easy stages this wonderful Course takes you into "Wireless." The mysteries of "Wireless" are unfolded to you by the use of such simple language so skillfully used, that of necessity you must understand every word. The subject is not treated superficially, however, for there is a whole lesson devoted to the Theory and Mathematics of this epoch marking subject. To lend charm to the Course, the last Lesson (No. 20) is devoted to a history of Wireless and the men who developed it. The wireless course positively cannot be bought, but will be sent absolutely free with a full year's subscription (12 numbers) of the Electrical Experimenter at $1.00. It's the biggest dollar's worth you can ever buy anywhere at any time. Send for it to-day enclosing $1.00. Send **now** before you forget.

The coupon below is a convenient way. **But do it now.**

HENRY ZUHR

32-34 Frankfort St. New York City

of the latest type electrically-driven gyroscopic-compass.

The submarine also has suitable running and signaling electric lights at her masthead. The steering is done by electric motor control and the boat carries an electrically driven capstan and other refinements such as electrically vibrated submarine signal to be used in case of distress, etc., and which sends out powerful vibrations through the water which may be picked up by the mother ship of the flotilla.

The modern submarine is, furthermore, equipped now with a complete telephone installation as well as speaking tubes from the officers' central control deck, so that orders may be transmitted from the commander's position before the periscope to any part of the boat instantaneously. It is now common practise to fit the submarine with an auxiliary electric lighting system equipped with 6-volt portable lamps and storage battery as well as dry battery, in order to operate same for several hours in cases of emergency.

In time of war it is thus seen that the submarine commander has a very highly perfected and centralized means of control which is at his fingers' ends, so to speak. When he has sighted a warship of the enemy which is to be torpedoed, which sighting is done by coming to the surface for a few minutes so that the periscope projects above the water a foot or so, he then gets the range and swings the submarine so that one of her torpedo tubes is pointed in the proper direction at the enemy ship. He can then press an electric button which controls the compressed air discharger of the proper torpedo tube, and he will then, and generally does, submerge instantly.

All of this may sound complicated, but as a matter of fact it only requires a few seconds, or at most a few minutes, to bring the submarine torpedo tubes into the proper angle to hit the enemy's ship, momentarily rising to the surface so that the periscope will give a view of the target for range-finding so as to accurately discharge the torpedo.

In most cases, before the gun pointers of the warships can discharge any shells at the submarine it has sunk from view, and the next minute they may be hit by the terible torpedo, which has the power, in most cases, to quickly sink the most powerful and heavily armored dreadnought afloat. The torpedoes fired have a range of two to three miles and even more in some types. It should be noted that our illustration does not show every detail, such as chairs, tables, bunks, etc., as these are outside the scope of this treatise.

MARCONI INJUNCTION HOLDS.

Judges Lacombe, Ward and Rogers, sitting in the Circuit Court of Appeals, handed down a decision recently affirming the order of Judge Hough granting a preliminary injunction to restrain the de Forest Radio Telephone & Telegraph Co., the Standard Oil Co. of New York and Lee de Forest from infringing the fundamental Marconi and Lodge patents relating to wireless telegraphy.

It had been urged by the defendants that it was unfair that they should be restrained from the use of the de Forest system pending the determination of the patent action brought by the Marconi Wireless Telegraph Co., on the ground that the Marconi people had recently raised the price it charged steamship companies for the use of its system to $100 a month for each vessel.

Opportunity Exchange

YOU will probably find more opportunities and real bargains in these columns than anywhere else in the country. Most good things in life are hard to find and worth going after—these little ads illustrate that point; you alone will be the real loser if you don't take the time to scan through these columns.

Advertisements in this section 4c. a word for each insertion. Count 7 words per line.

Name and address must be included at the above rate. Cash should accompany all classified advertisements unless placed by an accredited advertising agency.

Ten per cent. discount for 6 issues, 20 per cent. discount for 12 issues from above rate. Objectionable or misleading advertisements not accepted.

Advertisements for the August issue should reach us not later than July 10th.

Brooklyn, N. Y., April 15, 1915.

Gentlemen:—The results obtained from my advertisement in the "Electrical Experimenter" really surprised me; in fact the demand for a certain instrument of mine exceeds the capacity for manufacturing and it is all through the "E. E." To date, 79 inquiries, 12 orders. Might state last week filled a $50.00 order netting me a profit of $18.75. As to the exact value of my orders to date, I prefer not to give figures; however, you will always see my ad, month in and month out. I can truthfully say that the "E. E." has it on them all, viz., for quick results, interesting reading matter, etc. Very truly yours. HARRY Y. HIGGS.

2—¼-IN. Coils, good Punching Bag and Platform, 1 Vibrator, 1 Magneto. Want most any good radio instrument. Want offer. Ross J. Plaisted, Penn Yan, N. Y.

FOR SALE—Complete 1 K.W. Transmitting set, $20. Under ordinary conditions this set will send 50 miles. This set is similar to that of the Electro Importing Co.'s No. S.O.-200 outfit and is in excellent condition. Also have a 1½-in. Bulldog Coil, $3. Would like to exchange photos of radio station. Cecil Bridges, Louisville, Ill.

EXCHANGE—E.I. Variable Box Condenser, good as new. Will exchange for transparent 43 plate Variable Condenser. Louis L. Brandmeyer, Jr., Watertown, Conn.

FOR SALE—4 H.P. Steam Engine, horizontal style, $25; worth double; Rayfield Carburetor, fine condition, $9; new loud Auto Horn, $4. Bargains. Peter Nowak, 941 Merrill St., Milwaukee, Wis.

THE NEW
MURDOCK SPECIAL No. 55
WIRELESS RECEIVERS

With Regular Head Band

Complete 2000 Ohm Double Head Set

ONLY

$4.00

With Coronet Head Band $4.50

Absolutely high grade real wireless receivers, equal in sensitiveness, quality of materials, and dependability to any obtainable anywhere at many times the price.

We will, upon receipt of price, deliver a Murdock Special set, with the privilege of fourteen days trial. If for any reason the purchaser is dissatisfied, either with the receivers or our claims, the purchase price will be immediately refunded upon return of receivers.

WM. J. MURDOCK CO., 55 Carter St., Chelsea, Mass.

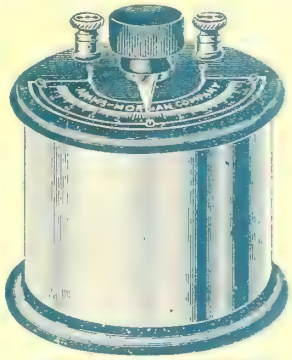
STOP!

We hereby present one of the greatest bargains in electrical literature ever offered.

A complete Volume of the *Electrical Experimenter*, bound in rich, dark green linen, stamped with gold letters at the extraordinary low price of

75c.

Volume contains twelve numbers (from May, 1914, to April, 1915), **240** pages, **350** complete articles, **550** illustrations, **396** questions and answers.



A world of electrical information; the entire electrical Progress for one year; the greatest reference book on current "Wireless"—all at a price as low as the *unbound* copies would bring. Mind you, the book is durably bound with heavy covers. You will be proud to have it in your library. We have only a few hundred copies, therefore be sure and order today. Shipping weight 2 lbs. Add a sufficient amount for postage.

Sayville

SAYVILLE and Tuckerton are at present the only links connecting the American Continent directly with the German Empire. Both stations can now receive and transmit wireless messages to and from Germany, without any relaying means, at any given hour of the day.

First Tuckerton and now Sayville have been taken over by our watchful Government with the evident intention of preventing the two stations from committing an unneutral act, in conformity with international law practice.

The layman will immediately ask, that if the United States Government takes over the wireless plants, why does it not also take over the various transoceanic cable stations? He furthermore cannot see what harm the wireless stations can do, because they have been required for some time to use plain English or plain German, no code messages having been allowed since the outbreak of the war.

The answer is simple enough. A cable message during the time of its dispatch stays on the cable. It has only one destination; no one can "tap" the message without serious difficulties. Not so with the "wireless." Its waves being propagated in every direction, a thousand stations, or more, if properly equipped, can catch the message anywhere within the receiving radius of the sending station.

No doubt the far-seeing shrewd German Government long ago foresaw the possibility of a war with England and the inevitable isolation of the empire which would result in consequence thereof. It clearly foresaw the cutting of its cables by the enemy and it acted accordingly. Sayville and Tuckerton was the answer. Thus when England actually did cut the German cables early in August, 1914, Germany was by no means isolated telegraphically. Thanks to the wireless, which a wise government had long before planted on foreign soil, telegraphic traffic between America and Germany goes on the same as before, with the difference that the messages now travel over the very heads of Germany's enemies. With the inauguration of the German submarine warfare, the German Admiralty doubtless found a powerful weapon in the shape of the Sayville and Tuckerton wireless stations. The two stations being controlled almost entirely by German capital, it was reasonable to expect that they would support the German navy and its submarines to the best of their ability. Before the United States Government took over the Sayville station, early in July of this year, we had been reading a lot of nonsense as to some new devices being employed at that station which were supposed to be used in sending out messages by means of a special time-spacing system between the dots and dashes, as well as by varying the length of the dots and dashes themselves, which latter make up the telegraphic alphabet. Such a thing is, of course, not impossible, but why should it be done if much simpler means are at our disposal?

Let us imagine the following: A German spy is located on the ocean liner *Adriatic*, headed for Liverpool. When the ship is two days out the spy learns that the ship, on account of submarine danger, will not dock at Liverpool but at Greenock (Scotland) instead. This is important information. Within ten minutes he has sent a wireless to a stockbroker in New York as follows:

H. P. Frye & Co.,
235 Wall Street, New York.
Sell at once 2,000 *shares U. S. Steel at* 58.
John Miller.

When Frye & Co. receive the message they consult their code book and find that it reads thus:

Adriatic will dock at Greenock.

Within twenty-five minutes after John Miller handed his message to the operator on the *Adriatic* Sayville has received and dispatched the following message to its Nauen (Germany) station:

F. S. Schneider & Co.,
Friedrichstrasse, Berlin.
Cannot dispose 2,000 *shares U. S. Steel at* 58. *Are bid* 55½. *Advise.* *Frye & Co.*

This message is promptly received by the German commander of the submarine U-69, bobbing up and down not far from the south coast of Ireland.

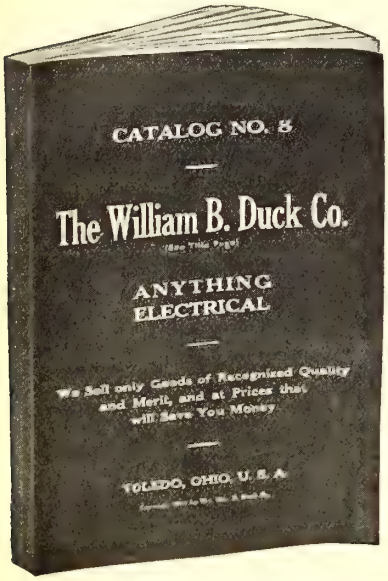
He also consults his code book and deciphers the harmless message thus:

Adriatic will dock at Greenock next Tuesday.

With this intelligence the German submarine commander is enabled to change his course in order to successfully hunt his quarry.

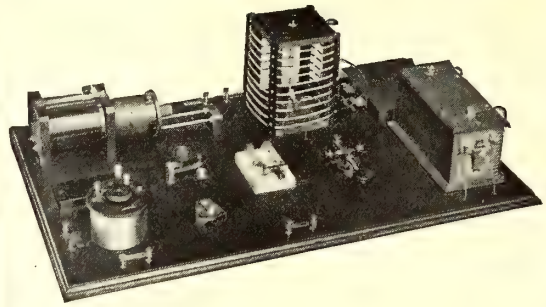
This is only one of the ways how the wireless stations at Sayville and Tuckerton can be used successfully to violate our neutrality; there are undoubtedly scores more.

In view of the above it is not quite clear how the United States Government, even by exercising the greatest care in censoring messages, can hope to prevent at all times the dispatch of unneutral wireless messages.

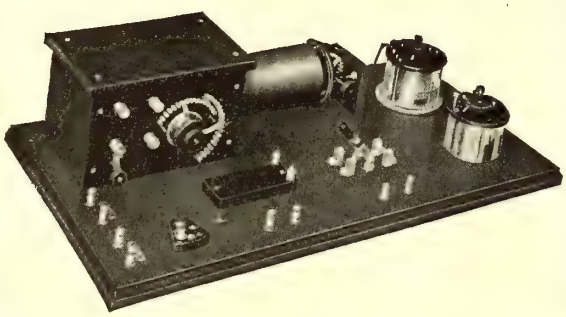


H. GERNSBACK

THE GREATEST SALE OF WIRELESS INSTRUMENTS IN THE HISTORY OF WIRELESS



Ninety of our most popular instruments including 16 new complete transmitting and receiving sets are to be sold at 25% to 35% below regular prices until August 15th.



SEND FOR PAMPHLET TODAY SHOWING THESE WONDERFUL VALUES. IT'S FREE.

SEE OUR BIG SEVEN PAGE WONDER ANNOUNCEMENT IN THE AUGUST ISSUE OF WORLD'S ADVANCE MAGAZINE, which contains the special prices on these instruments with cuts, descriptions and prices on all the new mounted sets.

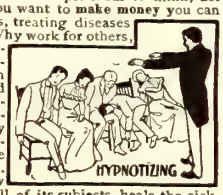
Have you this unrivaled catalog, the largest and most elaborate and comprehensive wireless and electrical catalog published? Contains 320 pages. Mailed only upon receipt of 8c. in stamps or coin (the wireless section only containing 125 pages, upon receipt of 4c. in stamps), either of which amounts may be deducted on first $1.00 purchase. Great cost of catalog and low prices prohibit distribution otherwise.

WHY SUCH PRICES

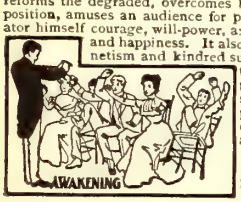
The reasons for this unusual sale are set forth at length in our 7-page announcement in the World's Advance. Briefly, the reasons are to create a greater interest in wireless among the masses of the people; to introduce our new unrivaled combined mounted transmitting and receiving sets, which could not be put into our next catalog until the fall, and to emphasize the facilities we have for taking care of our enormous patronage.

OUR NEW MOUNTED SETS

We know that we strike a popular chord among wireless enthusiasts in putting out our new mounted combination transmitting and receiving sets. To our knowledge there are no first class sets of this type on the market. Practically all the instruments in these sets are among our most popular sellers and will be found described at length in our No. 8 catalog. To make these sets in every sense popular we have put prices on all of them that are within the reach of the average experimenter. In fact a reference to the list prices in our No. 8 catalog of all the instruments in these sets show that very little extra is added for the base, wiring and mounting of the instruments.



The cuts do not begin to do these sets justice. All the instruments are mounted on a beautifully finished mahogany base. The finish on the most inexpensive sets selling as low as $10.00 is equally as good as the finish on the most expensive sets. All the wiring is concealed in slotted grooves underneath the base. A double pole double throw switch is provided on each set for connecting from transmitting to receiving set. Switch is also provided on all the transmitting and receiving sets for short circuiting the detector when the transmitting set is in operation. Etched brass name plates are provided at all terminals showing the various connections.



THE WILLIAM B. DUCK CO. 230-232 SUPERIOR ST. TOLEDO, OHIO

HYPNOTISM!

Be a HYPNOTIST and MAKE FUN and MONEY!

It takes but a few hours to learn. The study is both easy and fascinating. Hypnotism is an endless source of fun and wonder. If you know how to Hypnotize you can perform some of the most marvelous feats imaginable. You can do a hundred amazing things that other people cannot do. You can surprise your friends and make yourself popular. You can place others under this strange and mystic spell. You can compel them to think, act and feel just as you wish. If you want to **make money** you can do so by giving entertainments, treating diseases or teaching the art to others. Why work for others, when you may master this money-making profession so easily? Investigate **NOW!** You may learn at your own home. I will send you my **free treatise** for the asking. It tells you about Hypnotism and how you may easily learn it. It is profusely illustrated and is written in a simple style easily understood by all. Anybody may learn from it of how the Hypnotic Spell sways the will of its subjects, heals the sick, reforms the degraded, overcomes bashfulness, helps to trade or position, amuses an audience for profit, and gains for the operator himself courage, will-power, and a means to health, wealth and happiness. It also treats fully on Personal Magnetism and kindred subjects. Remember, this treatise is **absolutely free.** Simply write for it, and it will be sent by next mail, all charges paid. Don't send any money or stamp, but send your name and address **today.** Address:

M. D. BETTS,
Sta. 563, Jackson, Mich.

MORE MONEY FOR YOU

Television, or The Projection of Pictures Over a Wire

By H. Winfield Secor

PROBABLY there is no more interesting, and as yet unperfected, branch of science than that of *Television*, or the process of transmitting and reproducing a scene or a person's likeness over a wire, such as a telephone circuit, so that, for instance, a person telephoning over a line can see on a screen in front of him the person to whom he is talking.

There have been many attempts made to solve this fascinating problem. Several European scientists, including the late E. Ruhmer, of Berlin, succeeded in constructing such an arrangement for the simultaneous transmission and reproduction of living pictures over a wire by utilizing a great number of selenium cells, mounted very compactly in a small flat area.

Selenium, as we know, changes its electrical resistance proportionately to the amount of light thrown on same. Therefore, as every picture is made up of light and dark shadows, it is evident that if such a picture is properly projected on a group of selenium cells that the different cells will change their electrical resistance proportionately to the amount of light projected on them and corresponding conjointly to the light and dark shadows of the view before the instrument. Simply explained, this system works as follows:

Each selenium cell on the transmitter would be connected up with its individual lamp (very small, of course), and thus it is perceived how, at the receiving station a picture or view could be reproduced in black and white and intermediate tones, for the reason that each selenium cell would allow a different amount of current to reach its individual lamp.

This may seem a little ambiguous or complicated to those not familiar with the subject, but what we are driving at may be the more readily perceived or understood by inspecting Fig. 3A. The portrait photographed, reproduced by the half-tone process, exhibited at Fig. 3A, is photographed onto the copper plate used in printing the reproduction on this page, through a finely ruled glass screen. This screen therefore causes the original photograph to be broken up into many small dots. The illustration here referred to, for instance, has about 140 dots to the inch. By looking in an ordinary manner at the photograph here reproduced, no distortion is noticeable, and the picture appears quite natural. Nevertheless, *it is made up entirely of dots.* You can convince yourself of this by inspecting our illustration with a good lens. This brings out the logic of the argument previously referred to, viz., that it is possible, theoretically and practically, to make a machine that will reproduce a picture by such an arrangement of dots or points; whether all of the dots necessary in building up the picture are simultaneously thrown on the screen of the Television apparatus, or whether these dots are successively or very rapidly thrown on the screen, one after the other.

The second view, at Fig. 3B, shows a largely magnified portion of the (marked) eye on the face of the half-tone cut. This shows how the reproduction of the face is made up of small dots, and by closely looking at any newspaper illustration, which is usually photographed through a coarse screen, this *dot make-up* of the picture will be very evident. Some illustrations in magazines and books, which are reproduced on highly polished and specially coated paper, are photographed through such a fine screen that the keenest eye cannot perceive any break-up or dot formation.

As aforementioned, a number of work-

Fig. 1, at Left, Shows Image of Man at Right Being Transmitted and Reproduced on Screen in Front of Lady. Her Face is Transmitted and Reproduced at Fig. 2 (Right) Before Man. Mr. A. A. Campbell-Swinton's Scheme.

THE ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is $1.00 a year in U. S. and possessions. Canada and foreign countries, $1.50 a year. U. S. coin as well as U. S. stamps accepted (no foreign coins or stamps). Single copies, 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of THE EXPERIMENTER PUBLISHING CO., INC. If you change your address notify us promptly, in order that copies are not miscarried or lost.

All communications and contributions to this journal should be addressed to: Editor, THE ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York. Unaccepted contributions cannot be returned unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

THE ELECTRICAL EXPERIMENTER. Monthly. Entered as second-class matter at the New York Post Office, March 1, 1915, under Act of Congress of March 3, 1879. Title registered U. S. Patent Office. Copyright, 1915, by E. P. Co., Inc., New York. **The contents of this magazine are copyrighted and must not be reproduced without giving full credit to the publication.**

ers have endeavored to solve this problem of "seeing over a wire," as it is commonly referred to, and one of the best methods tried in a laboratory, on a crude scale, is that of making use of a large number of selenium cells.

However, there are several drawbacks to this solution of the problem, some of them being enumerated below.

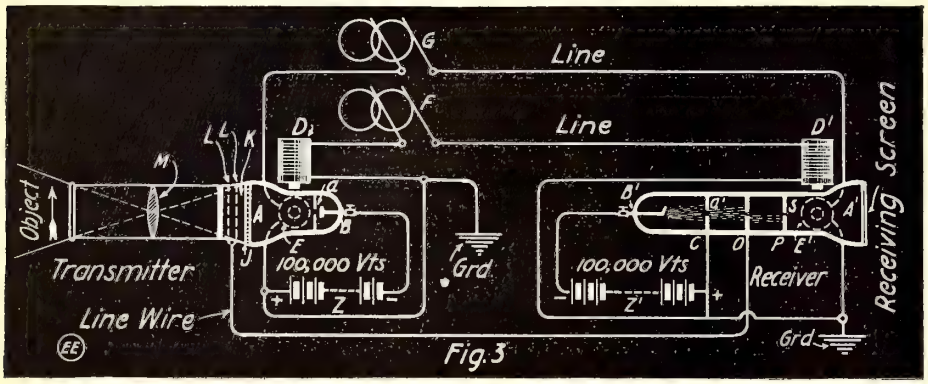

Fig. 3. Diagram of Proposed "Television" Scheme.

Selenium cells manifest a quality known as "time lag" in their electrical operation or action, and this means that it is difficult to build any such apparatus, as we now have under consideration, to act in an anywhere near perfect manner, when the selenium cells will show varying degrees of "time lag," or, in other words, when they tend to be sluggish in their action of changing from high to low resistance, etc. This lag is small, of course, and it must be understood that in considering the basis of this whole process that with the dot formation, even though made up of a vast number of small lamps, compactly grouped at the receiver end of the line, that the changes in the lamps' intensity, which is of course primarily dependent upon the action of the selenium cells on the transmitter, must be quite rapid, and this may be more readily understood when it is known that in the ordinary motion picture, with which we are all familiar, there

Fig. 3A. This Picture Is Made of Many Small Dots, Although You Wouldn't Think so. Note Marked Eye in Fig. 3B.

are from 16 to 20 different pictures projected on the screen per second. This has been found to give us a fairly steady picture owing to the "lag" of the human eye in perceiving an object in motion. That is to say, the eye does not loose its impression simultaneously, but the object's impression on the retina of the eye remains for a fraction of a second, and this explains how motion pictures are made possible by the present methods in vogue.

It has been estimated by a well-known English authority and scientist, who has worked along the line of Television, that if the selenium cell process was to be used to give good close-grained results on a surface only two inches square, there would be required 150,000 wires, 150,000 selenium cells, 150,000 lamps. While even to obtain an effect no better than that used in the coarsest process blocks, as used by ordinary daily newspapers, there would be required at least one-tenth that number of selenium cells, lamps and wires.

Working on this basis, but reducing the number of cells, etc., to be used, to a figure of 90,000, this scientist calculated that the cost for a 100-mile transmission circuit, including apparatus at both ends, would amount to the staggering sum of $6,250,000. This considers simply a monochrome reproduction in black and white only of the view or object over the circuit. If the apparatus in question should have to be triplicated, so as to give a colored picture, by the well-known three-color process, then the cost would naturally rise to three times the amount stated.

From this figure it is to be seen that evidently such a solution of the problem is far beyond us and not capable of industrial or practical applications, in the strict sense of the word.

Some workers in this field have also devised or advocated at different times very clever and ingenious methods, which seem quite good theoretically, for using a less number of selenium cells, lamps, etc., but to gain the same effect as if a large number of cells were used, by suitably moving a beam of light over the various cells successively at very high speed, and some similar arrangement being used at the *lamp* end of the circuit, where the picture is to be reproduced. This would act upon the principle of the retina retention of impression, as previously mentioned, and such ideas are based upon the theory that with proper apparatus, which unhappily is nearly impossible to construct from a mechanical standpoint, that each cell could be used for a fraction of a second.

One of the latest and most promising (theoretical) systems of Television—the *Telephot*—or the instrument for "seeing over a wire," makes use of a stream of cathode rays, which can be deflected and changed in their direction of production very rapidly, and moreover, these rays possess an infinitesimal amount of momentum or mass. This method has been brought forth by an Englishman, Mr. A. A. Campbell-Swinton, president of the Röentgen Ray Society, of London.

The apparatus based on his descriptions and ideas are shown in the illustration at Figs. 1 and 2. In this picture detailed apparatus only is shown for transmitting pictures one way, or, in this case, from right to left; the detailed receiving apparatus being then at the left of the picture and the transmitting apparatus with high frequency A. C. generators, etc., being shown at the right. Both transmitting and receiving tube openings are shown, however. It is evident that one can easily, and without any awkward motions, glance slightly upward to view the reproduced face in the smaller upper screen, which is shown placed at a small angle. A dictagraph or super-sensitive telephone transmitter is probably best for such instruments and is observed under the *television screens.* Six wires are required to transmit pictures both ways.

We may now briefly consider the operation of this apparatus advocated by Mr. Campbell-Swinton, and which has been favorably received by the scientific world, *although as yet not practically demonstrated.* The schematic diagram, Fig. 3, will help the reader to understand the diagnosis of its operation. Three line wires are necessary between the apparatus, as observed from the illustrations at Figs. 1 and 3. At the *transmitter* end of the line there is used a focusing lens barrel "X." The object whose reproduction is to be electrically transmitted over the line is arranged at the tube opening, as at "N." A Crooke's vacuum tube is used at "A" and at "B" is the cathode electrode of the tube, from which the cathode rays are shot forth at an incredible velocity and which have

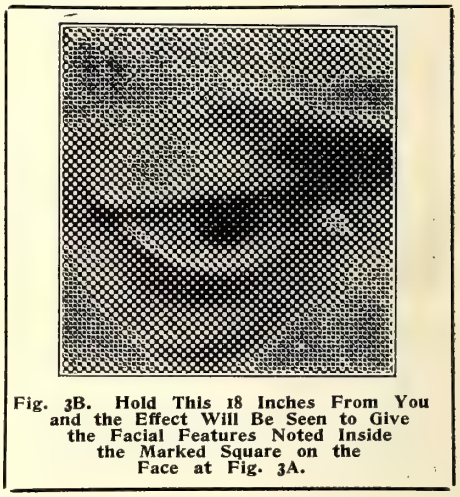

Fig. 3B. Hold This 18 Inches From You and the Effect Will Be Seen to Give the Facial Features Noted Inside the Marked Square on the Face at Fig. 3A.

practically no mass or momentum. An anode "C" of circular form is placed in the tube, which has at its center a small aperture or opening "a." Through this opening a small stream of cathode rays may pass; these rays being produced by a high potential *continuous current* from a source "Z," giving in the neighborhood of, say, 100,000 volts. Placed at right angles about the tube "A" are two electro-magnets "D" and "E," and these are energized by alternating currents from the A. C. generators or dynamos "G" and "F." These magnets allow of readily controlling or deflecting the cathode rays stream in a vertical and horizontal direction, respectively.

At "J" in the transmitter tube is placed a special screen, the whole surface of which is searched out by the stream of cathode rays, every tenth of a second, under the combined action of the A. C. electro-magnets "D" and "E." It should be mentioned here that the dynamos "G" and "F" produce *widely different* frequencies of alternating current; one of them producing, say, 1,000 complete positive and negative alternations per second, and the other 10 such complete alternations per second. The special screen "J" is proposed to be a gas-

(*Continued on page* 172.)

Submarine "Wireless" Signaling

THE subject of safety of submarines at sea is of vital importance, especially in the present submarine warfare, in which many of these under-sea fighters are participating.

It is well known that wireless telegraphy is now the most important factor of communication on our present ocean steamers and battleships, which aids their navigation and safety at sea; but when we come to the submarines, the wireless used on these craft cannot now be directly adapted to the under-sea fighters, as the etheric waves produced by the ordinary wireless apparatus cannot travel very far in water, and therefore other means of signaling becomes necessary. Many forms of apparatus were invented and used with considerable success, such as the submarine bell, which is still in service; but the distance traveled by the sound is so small that it is practically useless.

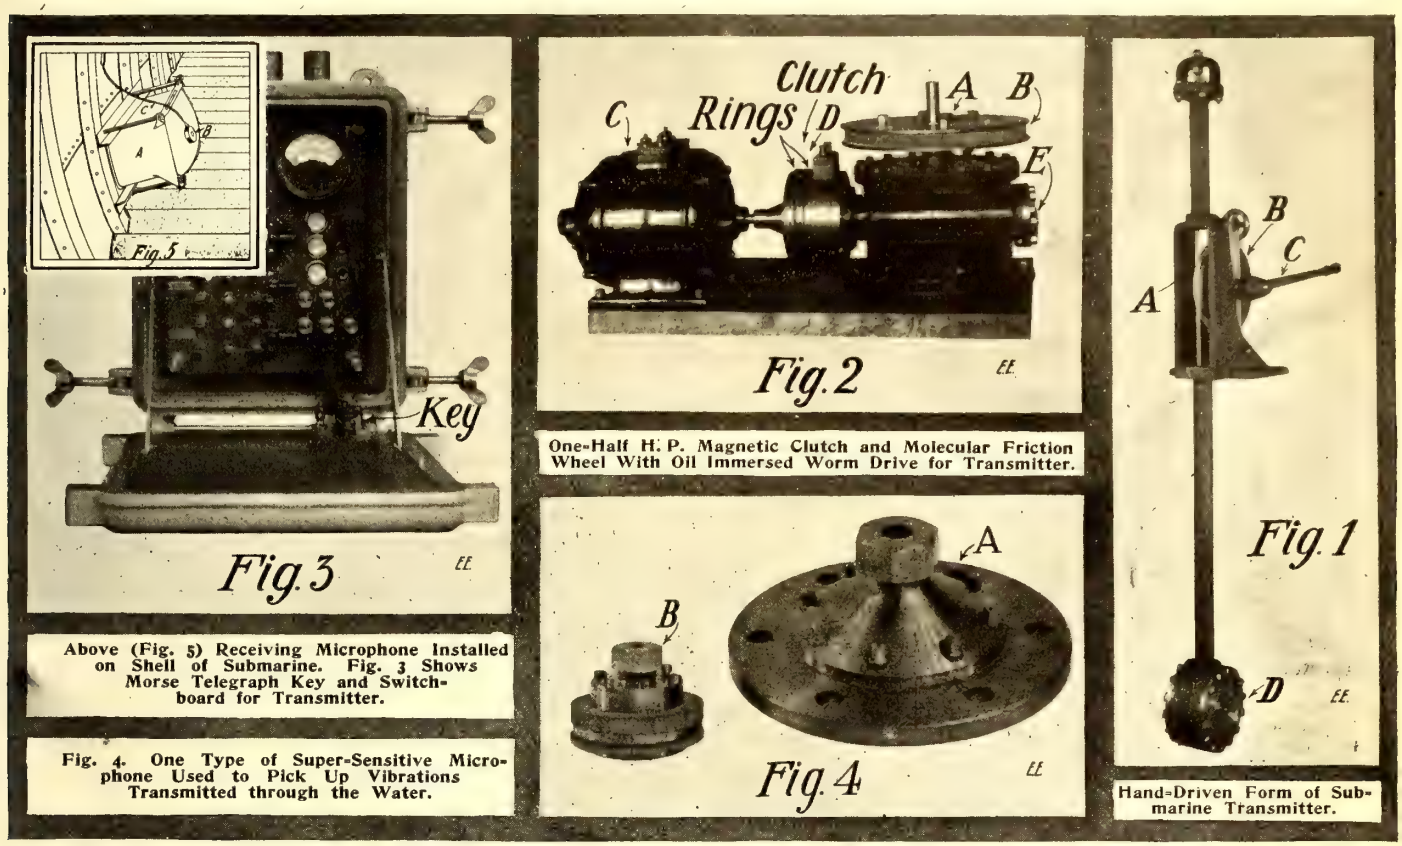
These methods were rarely used, however, until finally an Austro-Hungarian physicist, H. Christian Berger, who realized the necessity for an efficient means of submarine signaling between moving under-sea vessels, devoted his talents to the solution of the problem. He finally solved the problem by using the principle of longitudinal vibrations in a steel wire or strip set into vibration by frictional means.

His first transmitter consisted of a piano wire, as at A in Fig. 1, which is here shown a ribbon of only 2 millimeters diameter, set into longitudinal vibration by a hand-driven silk wheel B moistened with alcohol; D is a sounding chamber, which is immersed in the water. With this apparatus Morse dot and dash signals were clearly heard for 3 kilometers (1.86 miles). The sound had the qualities of the ordinary etheric wireless, and it has therefore been called submarine wireless.

These experiments were conducted on the United States submarine E-1, and were so successful that the United States officials were encouraged to build a large apparatus, using a ½-horsepower electric motor C, Fig. 2, to drive the exciter, and also the wire was substituted by a flat metallic ribbon having a thickness of 1/8 inch and a width of ½ inch.

The complete apparatus is shown in Fig. 2. A commercial type Morse key, Fig. 3, operates a magnetic clutch D on the shaft by pressing the key, thus supplying current to the electromagnets in the clutch and connecting the worm gear in case E, which is connected in turn to the felt-edged wheel A. This wheel contains a reservoir inside it, in which alcohol is placed in order to feed the felt continuously.

The operation of same is as follows: The clutch is connected and the steel ribbon is next stretched and placed near the felt wheel so it touches same. The motor is next started by pressing the Morse key. The felt wheel is set in motion, according to the current sent through the magnetic clutch, which is operated by the key and consequently produces friction on the ribbon, which is caused to rapidly vibrate. These vibrations are sent out on air waves and cause the hull of the boat to vibrate, and finally are communicated to the water. The water is thus also set into vibration and these vibratory tones are received by another vessel containing the proper receiving apparatus. The distance that these waves travel depends entirely upon the number of vibrations which the steel wire or ribbon emits.



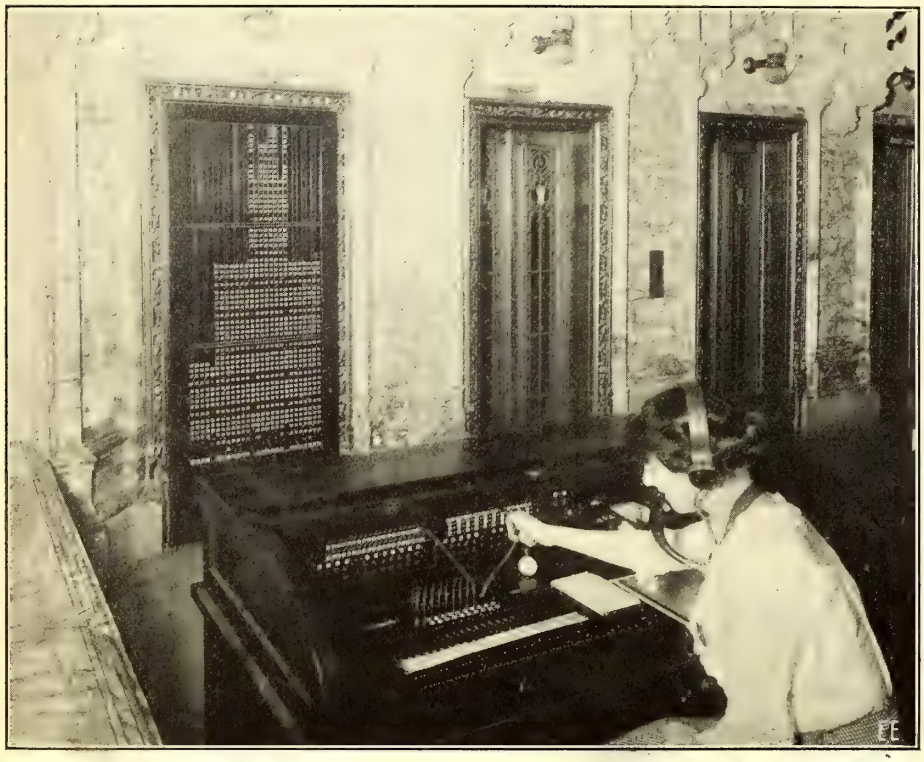
The receiving apparatus consists of a receiving tank, super-sensitive microphone, telephone receiver and battery. The receiving tank is placed on the hull of the boat as shown in Fig. 5 at A, and it is filled with water. The microphone transmitter B, Fig. 5, is placed in firm contact with the receiving tank and connected in series with a telephone receiver and battery by water-proof copper wires. The transmitter is then covered with a thick steel plate A. See Fig. 4.

The incoming waves or vibrations caused by the transmitter are caught by the receiving tank, and the microphone intercepts these faint vibrations, which vary the resistance in the telephone circuit, thereby giving the exact sounds as produced at the transmitting station. The water in the tank acts as a conducting medium between the hull of the submarine and the sensitive microphone transmitter, just as the ether acts as a conducting medium in aerial wireless telegraphy.

With this system signals were audibly read at a distance of 10 knots. The secret of the extraordinary efficiency of this system lies in the fact that the vibrations used are longitudinal and the stresses set up molecular. Unlike a plucked violin string, where the pitch depends on the tension, the pitch in longitudinal vibrations is independent of its tension.

As friction is always rhythmic, the exciter or felt wheel throws the wire into intense longitudinal oscillations, and a clear and absolutely uniform musical note is produced in the water. In order to produce a note of 1,000 vibrations per second, most suitable for microphones, the wire is cut for one-half a wave length. As the velocity of sound in steel is about 16,000 feet per second, the wire would be 1/2,000, or about 8 feet in length, and this would generate a sound wave of about 4.7 feet in water. So it must be quite evident that to transmit these vibrations for eight or 10 miles a longer wire must be used, or else a shorter wire having a greater tension. Therefore more power is required to set this wire in vibration.

This method of signaling has been approved by marine officials, and many of these apparatus are being used by Uncle Sam's submarines, with good success.



Above (Fig. 5) Receiving Microphone Installed on Shell of Submarine. Fig. 3 Shows Morse Telegraph Key and Switchboard for Transmitter.

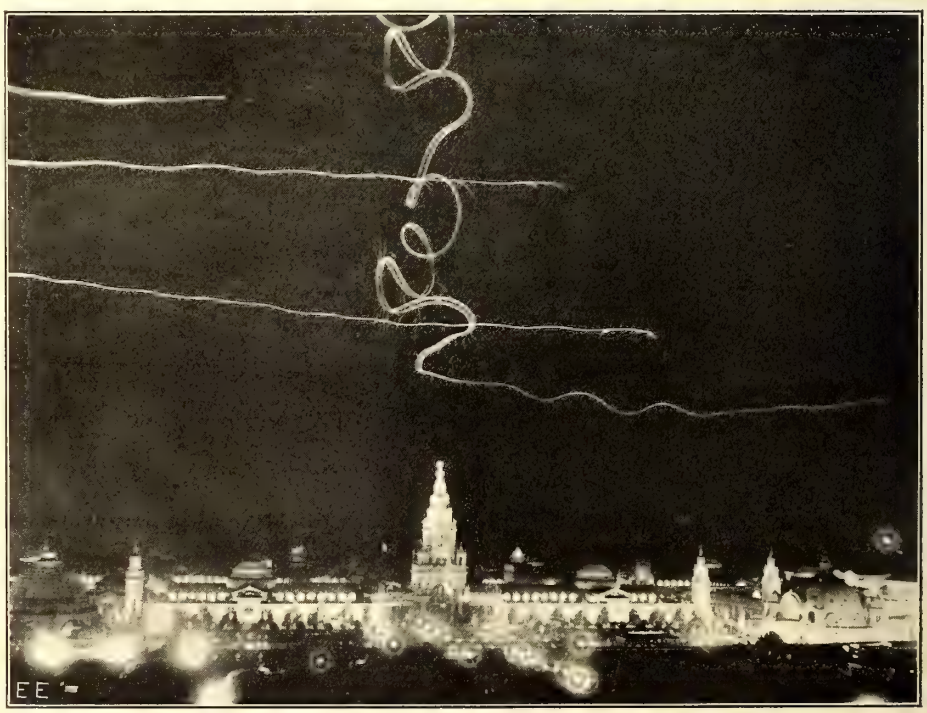
Fig. 4. One Type of Super-Sensitive Microphone Used to Pick Up Vibrations Transmitted through the Water.

ELECTRIC ELEVATOR CONTROL AT THE WOOLWORTH BUILDING.

One of the most striking objects at the Woolworth Building, in New York City, is the automatic elevator control, which is depicted in the accompanying photograph. The switchboard here seen is not a control board, similiar to that in an ordinary power house, but entirely new. It contains many small electric lamps, placed in a number of vertical rows, each row corresponding to an elevator, and the number of lamps in a row corresponding to the number of floors which that particular "car" covers. In this way the operator can readily see just where any of the 27 cars are located in all sections of the building. There are also a number of jack switches on the desk connected to telephones installed in each car, by means of which communication with any particular motorman is easily effected.

This system is very simple and works splendidly in large buildings where many elevators are in operation. Elevator dispatching is thus reduced to a science in the modern skyscraper.

This Girl, by Means of a Lamp Signal Board as Shown, Has Complete Control of the 27 Elevators in the Woolworth Building, New York City.



ILLUMINATED AEROPLANE GIVES SPECTACULAR EFFECT.

This is a bona fide negative taken of an illuminated aeroplane flight made by Art Smith, the "Upside Down Aviator," flying at night over the Panama-Pacific International Exposition in San Francisco. The picture was made from a single timed exposure on the night of May 27, and is now published for the first time. The shutter was exposed during the period of the flight.

The picture is unique, as it is the first photographic record of an aeroplane's course ever made on a single negative. While the course of an aeroplane may be recorded by a cinematograph film, a night exposure obviously is the only one capable of recording the course of an aeroplane on a single plate. A daylight exposure would show the aeroplane at but one point.

Owing to the high speed of the aviator's flight and the fact that only a portion of the aeroplane was illuminated the course of the flight only is marked on the negative, the aeroplane itself having escaped the camera. The parallel lines were made as Art Smith flew back and forth over the exposition grounds while gaining a height from which to loop the loop and turn the side spirals of which he is a master. These parallel lines apparently start or end in the dark, as from time to time the aviator shuts off the light from his aeroplane. The trail of light is caused by the flow of brilliantly illuminated white smoke and a discharge of white fireworks from a non-explosive smoke pot at the back of the aeroplane.

The lines above the Tower of Jewels, in the center of the picture, were taken as the boy aviator, with his aeroplane fully illuminated so that the thousands below might observe his flight, looped toward the earth. These lines show four distinct loops, in which the aviator turned complete circles in courses vertical to the earth and one back "upside down" loop.

Illuminated Aeroplane Describes Wonderful Effects Against Night Sky of 'Frisco Exposition.

HOW ELECTRICITY KILLS.

Ever since electricity was first used it has been known that under certain circumstances it was deadly, but just what these circumstances were and how electricity kills took almost endless experimenting to find out. The mystery of electricity's deadly power seemed to be one of those unanswerable problems which deal with the question of life and death, but now, thanks to the tireless energy of many scientists, the various results of their observations have brought the answer.

In the case of an electric shock severe enough to kill, death usually results from one of two causes—either from paralysis of the respiratory organs or from contraction of the muscular fibers of the heart. In the former case, the victim may occasionally be literally brought back to life by artificial respiration, but there is no known remedy in the latter case.

The effect of direct and alternating currents vary with the current strength, the duration of contact and the path through the body.

Lower animals are much more susceptible to electric shock than mankind, dogs being frequently killed by a direct current as low as 70 volts. The average man can take a direct current of 100 volts and scarcely notice it; 200 to 400 volts give rise to muscular cramp, while respiration is suddenly stopped at 550 volts. At 600 volts both contraction of the heart and respiratory paralysis begin, but at 2,300 to 4,800 volts the effect is usually confined to the respiratory organs. The electrocution records of various American penitentiaries show that two to seven amperes at 1,500 volts, 15 to 50 cycles per second, always stops the heart when continued 45 or 50 seconds.

A NOVEL DENTISTS' SIGN.

A clever advertising sign was recently made for an Eastern dental parlor. It is indeed unique and never fails to arrest the attention of the passing crowds.

This sign is an electrically operated *human jaw,* as seen in the photograph Fig. 1, and it consists of two parts, namely; the lower and upper jaws. They are constantly opening and closing. This is done by means of a one-eighth horsepower electric motor connected to a suitable gear which is linked up to the lower jaw frame. A large number of incandescent electric lamps encircle tis sign, which are lighted at night. Fig. 2 shows the sign when the jaws are open.

The size of the sign is 30 inches high, five feet wide and five feet deep, and the distance between the jaws when they are fully opened twenty inches. It weighs 400 pounds. Photos by courtesy of the Federal Sign System.

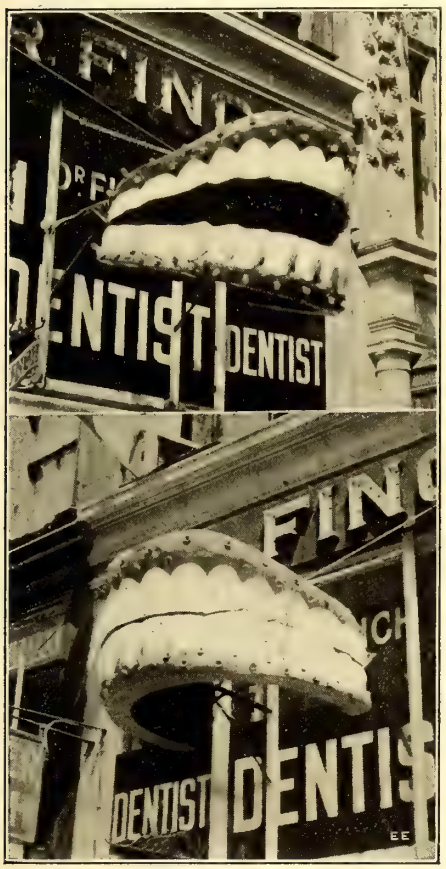


Fig. 2 (Above) Shows New Electric Dental Sign With Jaws Opened. They Open and Close Repeatedly; Fig. 1 (Below) Showing Them Shut.

CORRECTION ON TALKING PICTURE ARTICLE.

With reference to the article entitled "Talking Motion Pictures and Selenium," published in the June, 1915, issue of *The Electrical Experimenter,* we are informed by Ignatius H. McCarty, of San Francisco, a well-known wireless and electrical engineer, that he has done similar work to that mentioned by S. Wein in his treatment of the subject, and also he suggests that many details not mentioned in the article have been worked out by himself and his associates, necessary to the successful commercial application and adaptation of this ingenious scientific idea.

Mr. McCarty has been granted a basic patent on this method in France on September 26, 1912, the number of the patent being 448,757, and his United States basic patent bears application serial No. 701,219.

It is also stated in his communication that, in the apparatus used in his system, the speech accompanying the motion pictures is so perfect that it does not at all resemble a phonograph, and does not possess that "tin-canny" effect always so noticeable when the usual phonograph is used with a horn on same, or even when a number of horns are used. Also, this inventor claims to have invented a telephonic transmitter suitable for wireless and other work, which does not use any carbon, but instead a compounded product developed by himself, and which substitute is pronounced absolutely free from carbon, after chemical analysis. It is said to be far superior to the ordinary carbon transmitter, and is shortly to be tested out over the New York to San Francisco long-distance telephone circuit. It has also been tested with wonderful results over circuits 75 to 100 miles long, and works better in every way than the common carbon-grain transmitter.

Edison 3,000,000 C. P. Storage Battery Searchlight

Profiting by an experience of firemen in fighting the $3,000,000 fire at the Edison Works at West Orange, N. J., on Dec. 9, 1914, Thomas A. Edison has perfected another invention which he took to his home in Llewellyn Park recently to try out.

A few minutes after Charles Edison began operating the device for the edification of his father, people living in the valley east of Llewellyn Park telephoned Police Headquarters and asked, "What is that terrible light shooting out of the park?"

A policeman found Mr. Edison and his family enjoying the wonders produced by a new 3,000,000-candle-power searchlight, capable of throwing a ray several miles, the most powerful portable searchlight yet invented. It is very small and the power is supplied by storage batteries.

In the fire at the Edison plant the yards were thrown in darkness when the power was shut off. Mr. Edison conceived the idea of a portable searchlight, and two days after the blaze he had designed a working model. Now he announces the perfection of his idea.

It was said at the Edison laboratory that the lamp will be very useful in mine rescue work, at fires, and on ships, aeroplanes and locomotives. It can produce light in any volume desired, involving a new principle and making it of marvelous efficiency. A specially made incandescent lamp of high candle power is used in it.

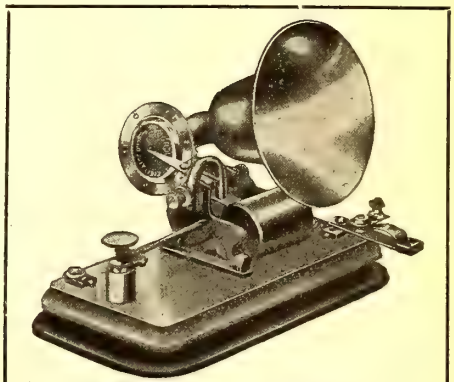
Thomas A. Edison Inspecting His New 3,000,000 C. P. Storage Battery Search Light.

MAKING TELEGRAPH RELAYS ACT AS SOUNDERS.



This is an age of improvement; new inventions for the betterment of the conditions of mankind and for his convenience are of almost daily occurrence.

Until quite recently, however, they have seemed to labor under the impression that the electric sounder had reached the perfect stage—that the local battery was a permanent fixture.

The new diaphragm telegraph sounder does away with both electric sounder and local battery. It is attached to the relay, and works from the main line battery.

Many devices have been employed with a view of making the relay loud enough to read without a sounder, but the device here pictured is claimed to be the only instrument that actually creates additional sound and intensifies it to practically any degree desired.

The concussion takes place within the air-tight diaphragm starting the vibration through the intensifier similar to the reproduction of the human voice by the phonograph. It has a strong, easily read, non-metallic tone that can be read with accuracy at a distance of a city block, and the adjustments may be so varied that no two instruments need sound alike.

New Amplifone Horn Converts Any Telegraph Relay Into Sounder.

Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

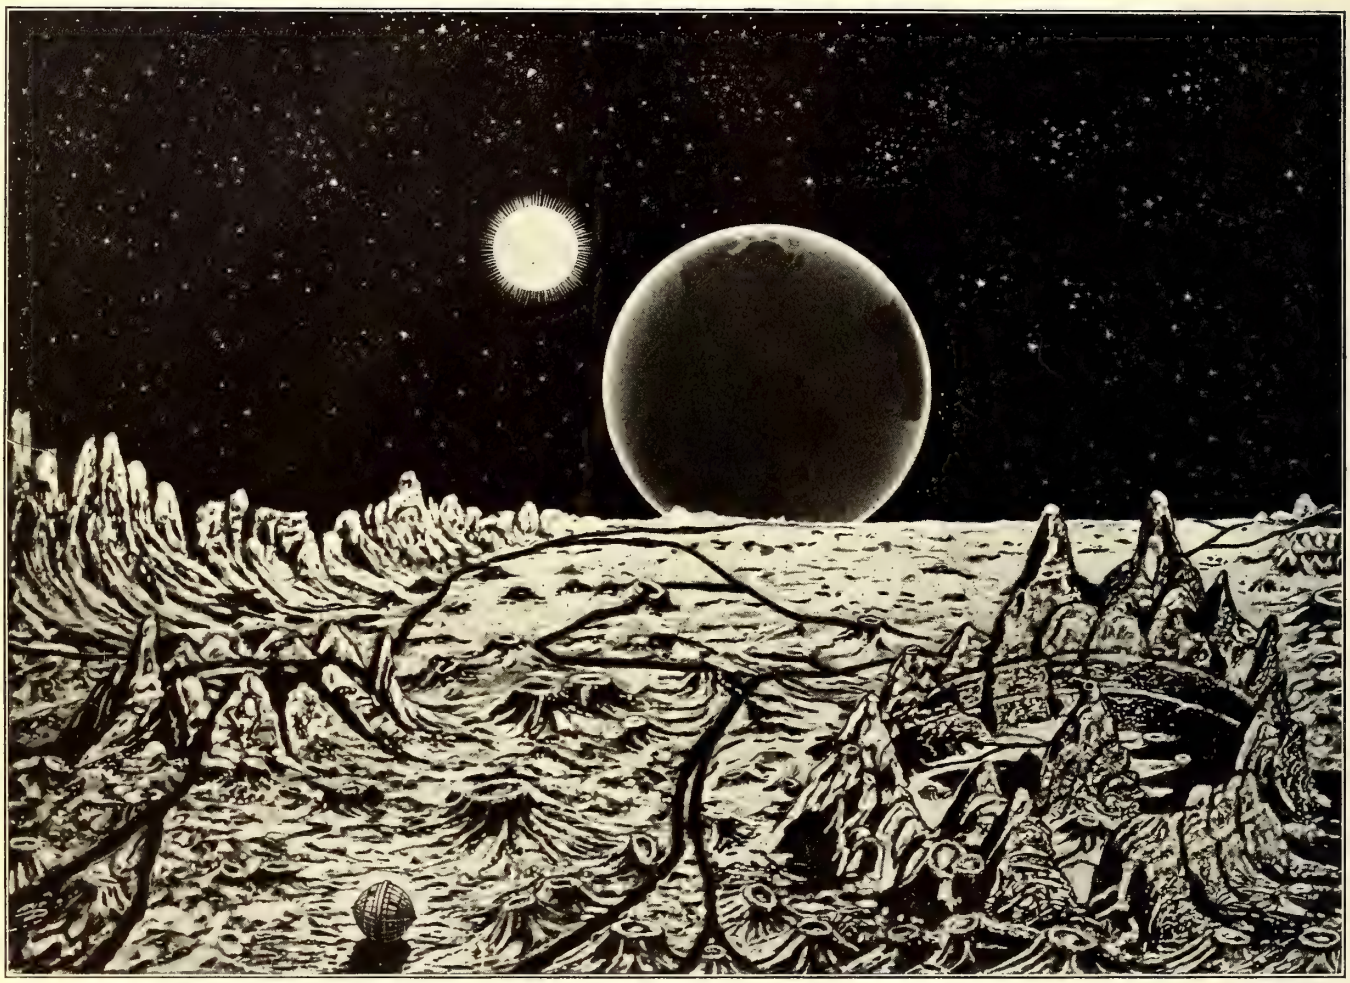
The Earth as Viewed from the Moon

I am in receipt of the following letter, postmarked Red Dog, N. M. It runs as follows:

deer (?) *mister i. m. alier,*

i am onely a uneducatet cowboy & perhaps i aint much sens but hear i have been reeding those gosh-darned münchenhaus storys of yourn & i am all het up about em i an my pal mike cokkleberry has tryed making hed or tale out of em but it aint no use

the first storys werent kwite so bad but they getting fierse as you rite more of em but you kapped the klimaks as mike sais when you rave about this graviti busness an try to mak us believ that a objeck between here and the moon weihs nothin at all a pound is a pound isnt it anywere? an mike sais that he lernt in scool that a lb of lead weihs as much as a lb of fethers, so mike figgered if that is true well then how coud you weih 28 lb on the moon if you weih 170 lb on the erth a lb is a lb isn't it? gosh darn nonsens it is thats what i sais it is an you now it is we may be igorant out hear in the wooly west but we aint that kracked yet by a darnsite that aint all, when mike & i red about that münchenheimer of yourn shoting rocksalt at them germins so they had to skratch themselfs which made them throw up their hants we sure thoght that it was a grate trik an we tryed it on bad man rogers when we sees him last weak we didnt wish to kill him ded just wanted to hav some fun & watch him skratch hisself when the rock-salt got under his skinn



so we lays for rogers near bulfinsh crik when he koms riding that there evening on his way to ed sweezys place sos he woudnt now from where we ambushd him we had fixt a maksim silenser on our rifels an insted of bulets we use your rocksalt to shoot at him well everything goes loveli he koms all stuck up as usal on that fool hoss of hisn an when he is jest bi we pot at em mike at his leg i at his bak the guns go fss-sst—fss-sst and thats all but he must have herd the klik of our guns and he weels around in his sadel but instead of skratchin hisself in a agoni as he should he sneeses and sneeses and sneeses fack is he almost sneest his fool hed of after a wile when his sneesing gets weeker an his swaring louder he looks around suspishes like but he dont see us an so he rides on after awhile

mike an i looks at each other flabergastet like and mike sais sais he, i had my suspishen of that feller alier now i now he is a fake darn his hide i thoght so to so we tryd it again & shot the salt again our windo pane when we git home wel would you believ it the salt never even touched the pane at all but when mike goes to inspeck the windo he almos sneeses his hed of that put us wise to it that when you shoot rocksalt from a gun it pulverises instinktly and the fine salt hangs in the aire around like a cloude of snees powder an when you git near it it gits in your nose an then you snees till the cows come home.

well maibe our salt wasnt as good as your frenchy kind & maibe we shoudnt of used a silenser on our guns but jest the same as a frend i adwise you never to kom out here to red dog for mike an i wont try rock-salt on you we'll use *reel* rocks

yours in disgusd

Bill snikeltree

* * *

When I had established my wireless connection with Baron Münchhausen that evening I immediately read the above letter to him and demanded an explanation. The Baron merely chuckled softly and said:

"My dear Alier, you ought to know better by this time than to doubt my word. I am always glad to give details of any general statement I might make at any time. In this instance let me state that your correspondent, who seems to have but a limited education, is, of course, right as far as he goes. My first experiments with shooting rocksalt were exactly as stated by your cowboy friend: the salt *does* pulverize before reaching the enemy—that is, *ordinary* rocksalt does. Not the kind, however, that I used for the French and English Allies. For when I found out that ordinary salt went up in dust when shot from a gun I promptly set out to remedy this defect. I simply ground up the rocksalt and by means of a chemical binder I formed a stiff paste; this was then compressed hydraulically in dies under an enormous pressure into little sharp-pointed bullets about ½ inch long. After drying, the bullets were ready to be used by our soldiers. These compressed rocksalt bullets did not pulverize, and while they had not the great penetrative power of an ordinary bullet, they accomplished the purpose for which they were intended very well indeed. I hope I have satisfied you and your correspondent's curiosity."

I apologized meekly to the Baron for having doubted his word, after which I added:

"The public down here, Your Excellency, has been very much impressed with your recent adventures on the moon. I am daily in receipt of correspondence from people from all parts of the world desiring particularly to know what the appearance of the earth is as seen from the moon. Many wish to know if large cities and rivers can be seen, and some even go as far as to ask if you can see trains and people move about the surface of the earth. Large bets are being made by people on the above subjects and the newspapers are being besieged for information day and night. They all have now put it up to me to procure first hand official information from you, and I trust you will be good enough in helping me to relieve the abnormal tension."

I heard Münchhausen laugh softly before he replied:

"Well, well! I would never have believed that people take such an interest in astronomy, but it certainly shows signs of progress by the human race and it is worth encouraging.

Without desiring to deliver a dry, astronomical lecture, I think it best to state a few fundamental facts in order that I can make myself better understood. Anyhow most people's astronomical knowledge is rusty nowadays. Therefore I hope I shall not bore you unduly.*

HAS it ever occured to you how the earth would look to you if viewed from the moon? Did you know that it is *new earth* on the moon when it is full moon on earth? If you don't know these things—and you certainly should know them—let Münchhausen tell you.

In this instalment he gives you true scientific facts in plain English. The story makes twenty minutes of pleasant as well as instructive reading.

The moon is about 240,000 miles distant from its primary, the earth. It revolves about the latter in 27¼ days, always turning one side to the earth. For this reason the inhabitants of the earth can never see more than one of the moon's hemispheres. Thus the moon revolving around the earth in 27¼ days turns just once around its axis during this time. Consequently the length of the moon's full day is 27¼ terrestrial days, which gives it a night of almost two of our weeks, as well as a day of like duration.

Now let us turn our attention toward the physical aspect of the earth as viewed from the moon. I am now sitting at the foot of a precipitous mountain close to the bulwark *Ptolemäus*, which is near the moon's equator. When I lift my eyes earthward I am presented a wonderful spectacle such as no other human eye has ever beheld. At this minute it is *New Earth* for us on the moon, i. e., the sun, earth and moon are in line, in the order named. As the earth is almost between us and the sun we naturally cannot see much of the former. For inhabitants on the earth it is *full moon* at this minute of speaking. In other words, when it is full moon on earth it is *new earth* on the moon; when it is *new moon* on earth it is *full earth* on the moon.

(To make the above plainer for the reader the author has inserted the accompanying diagram and the following explanation:

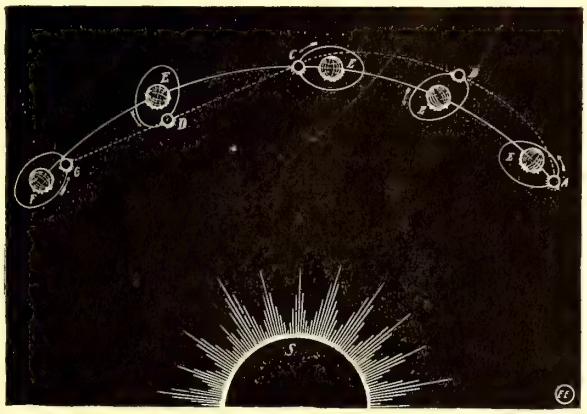
The plain line represents the orbit of the Earth; the dotted line represents that of the Moon.

At point A the Moon crosses a point of the Earth's orbit which the Earth has already passed. At the expiration of about one-fourth of a lunation she arrives at B, at which time the Earth is between the Moon and the Sun, consequently it is *full* moon; pursuing her course she is now in advance of the Earth and crosses her orbit again at C. From C she continues on her course till at D she is between the Earth and the Sun, consequently it is *new* moon; from D she approaches near and nearer to the orbit of the Earth till at G she again crosses it 240,000 miles behind the Earth. This completes one lunation or revolution of the Moon around the Earth.

In order to show how the Earth and the Moon are lighted up by the Sun the zig-zag lines around part of the Earth and the Moon in the diagram represent the portions which are lighted. Thus it will be readily seen that at A the Moon is in its *first* quarter as respects to the Earth, while the Earth is in its *last* quarter as seen from the Moon. At C this order is reversed.

Again at F we see a duplication of the phases exactly as occurred when the Earth and the Moon were in the position as shown at A.)

Now, then, as the sun shines on our full moon the sunlight is reflected down to the earth, half of which naturally is dark. i. e., night. It is now night for you, the moon lighting up your landscape. For this reason it is possible for me to *just faintly* make out the outlines of the American continents. But it is mostly blurred and very indistinct.



A little to the left of the earth I see the sun—a wondrous sight. As there is practically no atmosphere on the moon the earth as well as the sun sail in a pitchblack sky. For the sky on earth is blue only due to the terrestrial atmosphere and its diffused sunlight. On the moon there being practically no diffusion our sky is naturally black all of the time. The sun, as well as all the stars, shine with a tremendous brilliancy never seen on earth, for our little atmosphere cannot soften the penetrating glare of the heavenly bodies as does the earth's thick atmosphere. Neither do the stars flicker as seen from here, for the "twinkling" is not of the star's making, it is but a product of the earth's air which brings about this phenomenon.

Again gazing earthward this is what I see:

A big almost black disc appearing to me about 14 times as large as does the full moon on earth; old mother earth assuredly is an imposing sight. Around the circumference of the dark disc I see a wondrous pink fringe—it is the earth's atmosphere illuminated from behind by the sun's rays. It

*The balance of this instalment is based upon actual facts, according to tne latest lunar researches.—AUTHOR.

Explaining the Phases of the Moon and the Earth.

How Telephone Men Are Trained

TO the layman a telephone instrument is a rather mysterious contrivance. He knows that he has merely to signal the operator in order to talk into the transmitter and send his voice over the wires thousands of miles and through the receiver listen to another voice from many miles away. But the operation of the telephone system is not like that of a locomotive or street car, for example, because we can't see the wheels go round.

So when a telephone man comes to our office or residence to install a telephone or inspect and repair one which may be out of order, we may be pardoned for exhibiting a little curiosity as he deftly does his work. It all seems quite simple to him, however, because he has been carefully trained for this work, and every step has been taught him in a systematic and practical way.

The New York Telephone Co. maintains a plant school at 30 Gold street, New York City, where employees of the plant department are instructed in the work of installing and maintaining telephone instruments and the various methods of wiring, etc. It has been in operation since 1903, when it began in a small way as more or less of an experiment. It has grown steadily and taken its place as an important part of the company's organization, and many telephone men have received their first instructions in the principles of telephone practise here.

The object of the school is to interest and instruct the employees of the plant department in the telephone business, develop their ability to learn circuits and provide them with a suitable foundation upon which to build their knowledge of telephone practise as they gain experience in the field.

The period of instruction covers from 10 to 12 weeks, four weeks being spent in the school. The capacity of the school is sufficient for 50 students.

Three views of the highly developed plant training school maintained by the New York Telephone Co. are shown herewith. The illustration at Fig. 1 shows a general view of the school. Each student sits before a small switchboard with the proper devices on same specially arranged to teach him in the shortest time how telephone switchboards work, and also it is possible for the instructors in charge to throw a multitude of "faults" or troubles on the boards, and the time is then checked carefully which it takes the student to "clear up" all of these troubles. In some cases several hundred "faults," such as short-circuits between wires, grounded wires or cables, bell troubles, relay troubles, etc., can be simultaneously thrown on such a board, and the student is required to quickly clear up these artificially made "faults."

A closer view of students performing this testing and *trouble shooting* on switchboards is seen at Fig. 2. The students, as will be observed, are given personal instruction, and this of course conduces to their rapid education and training. A corps of telephone experts are in charge of the school who are men of wide experience in such matters.

In the illustration at Fig. 3 several students may be observed wiring telephone branch exchange circuits, this being *third grade work*, as it is termed in the school. This is very important work and must be learned exactly and the student must show considerable skill in handling the soldering iron, as many hundred small joints between wires and connecting studs are to be soldered in a very neat and workmanlike manner; or, in other words, the job must be done perfectly from a mechanical and electrical standpoint. A loose joint, caused by improper soldering, can cause a telephone circuit to be worthless for transmitting speech over. Hence, the great importance of training these men to do their work as perfectly as possible. They must know the why and the wherefore of everything.

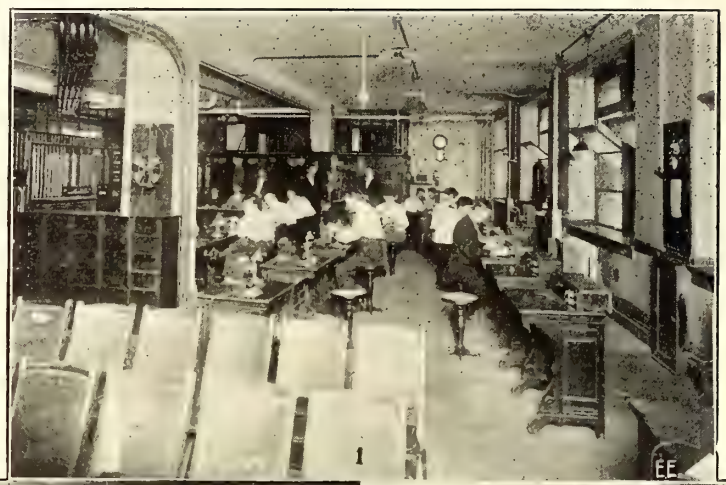

Illustration Fig. 1. Shows General View of the New York Telephone Co.'s Plant School. Fig. 2. Students Testing Sub-Station Instruments For Trouble—Second Grade Work. Fig. 3. Learning How to Wire Up Branch Exchange Circuits—Third Grade Work.

TO HONOR WIRELESS HEROES.

The dedication of the Jack Philips *Titanic* memorial fountain at the base of the tower of the United States Barge Office, New York City, took place last May.

President McAneny, of the Board of Aldermen, received the memorial on behalf of the city. It consists of a cenotaph shaft 8 feet high with seats on each side and a fountain in the center, all of granite, and a background of cypress trees.

The funds to erect the Philips Memorial were collected by the wireless operators on Atlantic and coastwise steamships on both oceans and amounted to more than $3,000. It is intended to have the names of all operators who have lost their lives while on duty inscribed on the cenotaph as a record of their bravery and to inspire others to emulate their example in the time of danger. The names on the memorial are:

George C. Eccels, s.s. Ohio, Aug. 26, 1909; Pacific Coast.

Stephen F. Sczepanek, s.s. Pere Marquette, Sept. 9, 1910; Lake Michigan.

Jack Philips, s.s. Titanic, April 15, 1912; Atlantic Coast.

Lawrence Prudhunt, s.s. Rosecrans, Jan. 17, 1913; Pacific Coast.

Donald Campbell Perkins, s.s. State of California, Aug. 18, 1913; Pacific Coast.

Clifton J. Fleming and Harry Fred Otto, s.s. Francis H. Leggett, Sept. 18, 1914; Pacific Coast.

Adolph J. Svenson, s.s. Hanalel, Nov. 23, 1914; Pacific Coast.

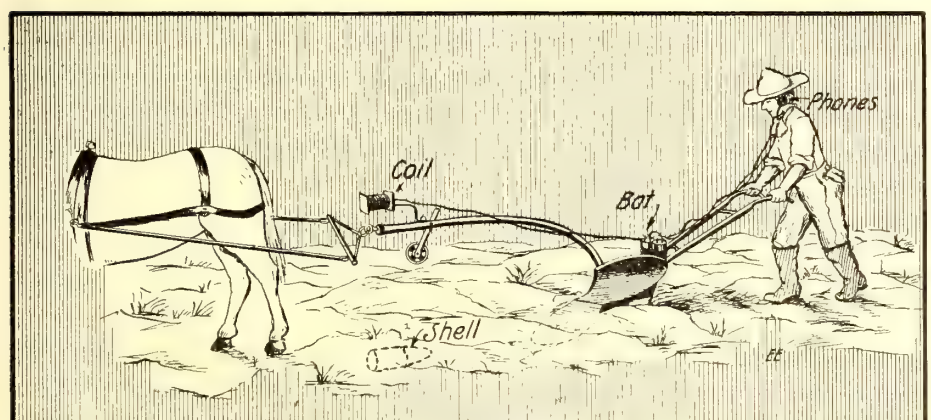
Ferdinand Kuehn, s.s. Monroe, Jan. 30, 1914; Atlantic Coast.

Walter E. Reker, s.s. Admiral Sampson, Aug. 25, 1914; Puget Sound.

Space is left for the addition of other names in the future.

NEW THERMOPILE FIRE DETECTOR.

A fire alarm system consisting of a number of thermopiles which are distributed throughout the building to be protected and which are connected in series to a galvanometer cabinet has recently been placed on the market. Connections are also made from the cabinet to fire alarm bells and to a trouble buzzer. The cabinet contains, in addition to the test resistors, the special galvanometer which is connected to the thermopiles. A break in the circuit, a drop in battery voltage or a total failure of the



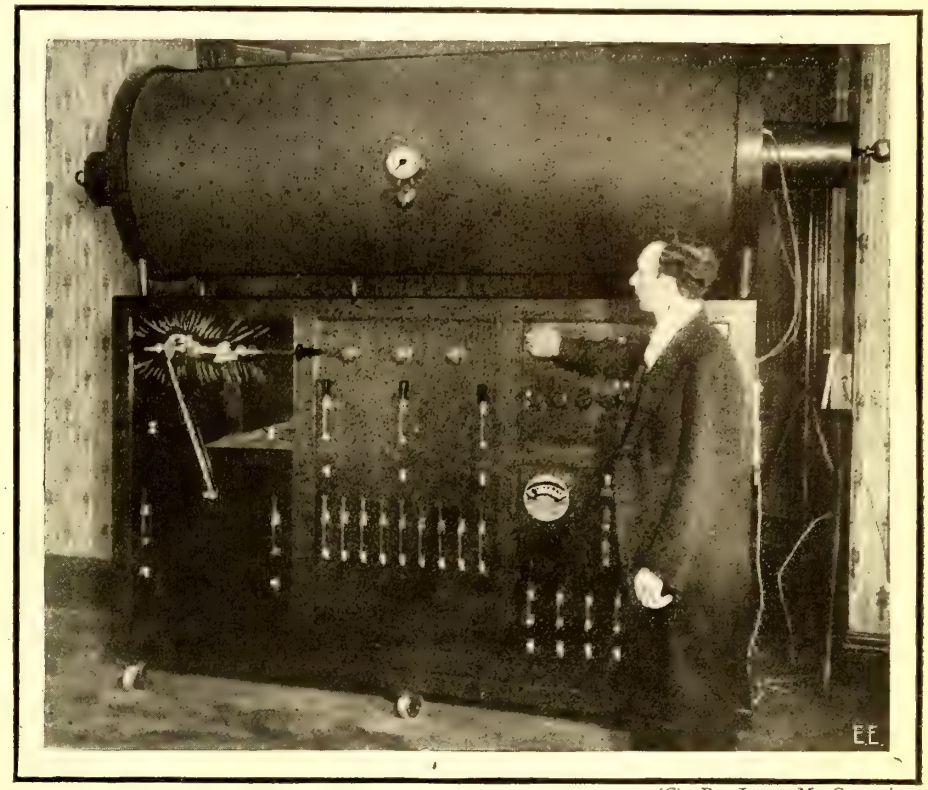
New Thermopile Fire Alarm.

battery will cause the operation of a trouble alarm, which continues until the trouble is remedied. The deflecting pointer of the galvanometer is held in its normal position by the test current in the thermopile circuit. When suddenly energized by current from the thermopiles the pointer is moved into contact, sending in a fire alarm, and when de-energized the pointer is moved into contact for the trouble alarm. The thermopiles consist of cubes of dissimilar metal connected in couples and mounted in porcelain. The joined ends of the couples are exposed, while the other ends are concealed in the base. According to the manufacturer, a temperature rise need not be more than 10 degrees Fahrenheit, but must take place within 60 seconds in order to operate the fire alarm. The alarm will be operated just as quickly whether the temperature of the room at the time of the fire is at zero or at any higher temperature. A single thermopile is designed to operate throughout a maximum floor area of 400 square feet. The maximum distance between centers of thermopiles in general is recommended to be about 25 feet, and in corridors 40 feet.

FINDING UNEXPLODED BOMBS ON EUROPEAN BATTLEFIELDS BY ELECTRICITY.

One of the most dangerous propositions the European tillers of the soil have to contend with under the present war conditions

The Plowman on European Battlefields Uses An Exploring Coil, Attached to the Plow, to Determine the Presence of Unexploded Shells.



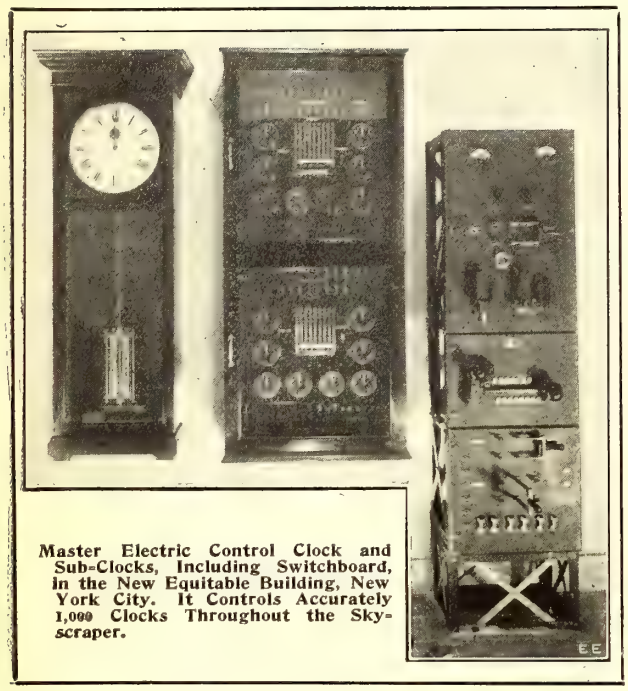
is that of running their plow into an unexploded shell. Most of these shells are exploded, as is well known, by coming in sudden contact with some other body, and, of course, a moving plow forms an ideal means by which to explode such shells, which may have buried themselves several inches in the soil.

To obviate this, there is now being used in France an electrical exploring coil, arranged to extend two or three yards ahead of the plow by being suitably supported on a small arm mounted in front of the plow, the coil being properly excited by a buzzer interrupted current from a battery carried on the plow frame. The man doing the plowing wears a set of sensitive telephone receivers on his ears, and whenever the coil, and conjointly the plow, comes within a couple of yards or so of such unexploded shells (which are made, of course, with a magnetic or steel jacket) a difference in the tone of the interrupted current in the head phones is perceived. He then knows that he should examine the ground carefully.

New Harmless Ray To Do X-Ray's Work.

Every person who has had experience with X-ray work knows of the severe burns which the ordinary X-rays give when worked with constantly. These defects are now overcome by the discovery of a new *ray* by Charles H. Stanley, of New York City. This new ray can be put to the same uses as the X-ray and more, and produces very satisfactory results. It is harmless and does not necessitate the operator "screening" himself in order to perform his work safely, as is the case with the old and dangerous X-ray.

Fourteen years of experimentation and research were expended before this new and harmless ray was perfected. The photograph herewith presented shows Mr. Stanley, the inventor, standing near his apparatus, which consists of a specially designed high frequency coil, producing a tension of one million volts and a discharge between two terminals, which can be separated 39 *feet apart*. This coil is so made that several different frequencies are sent to the X-ray tube, so that the production of the X-rays in the evacuated tube is constant and not flickering, as in the old tubes, using ordinary coils or high frequency machines. Note the immense size of the apparatus. This new ray cannot be developed with smaller apparatus, it is stated. Various kinds of current, such as Tesla, high tension, static, Oudin, etc., can be produced by this machine just by changing the switches, shown on the front of the apparatus.



(C) By Janet M. Cummings.

Marvelous New X-Ray Machine Capable of Producing Sparks 39 Feet in Length. Its Inventor, Charles H. Stanley, is Shown in the Picture.

So powerful is this ray that X-ray pictures can be readily taken 35 feet from the tube and strong effects are also produced on a fluoroscope. It has also a great healing effect on cancer, tumors and similar diseases which the ordinary X-ray has not, or at most to a very small extent. Therefore, this new invention may prove a wonderful remedy for the now incurable diseases. It is called the "Stanley Ray," after its inventor.

NEW ELECTRIC CLOCK SYSTEMS OF THE EQUITABLE BUILDING.

The most difficult problem of to-day in modern office buildings is the regulation of the clock system. The photograph here presented shows the complete mechanism for controlling one thousand electric clocks in the new Equitable building, New York City.

Master Electric Control Clock and Sub-Clocks, Including Switchboard, in the New Equitable Building, New York City. It Controls Accurately 1,000 Clocks Throughout the Sky-scraper.

The master clock is shown at the left, which is connected to two sets of relays mounted on a panel shown in the center of the picture. These relays are connected electrically to 16 different lines in the building to which all the secondary clocks in the separate offices are connected. The 16 secondary controlling clocks herewith shown in the panel are connected in parallel with each line. This is done to indicate to the operator the condition of the line. If any one of them stops he can readily see which line is out of order and thereby save time in finding the trouble. Each line has a set of fuses, and also the master clock circuit is properly protected by circuit-breakers on the main panel seen at the right of the photo.

The current used for this system is supplied by a storage battery of 24 to 30 volts, controlled by a switchboard seen at the extreme right. An end cell switch is provided for regulating the battery voltage. The clocks are electrically wound and synchronized by means of a step by step magnetic method. This clock system represents one of the finest and most accurate ever installed in this country. Compare this masterpiece of an "automatic electric timekeeper" with her 1,000 wards to the accuracy attainable if the old-time clockman regulated each of the 1,000 clocks by hand. —Photo by courtesy of *Architecture and Building.*

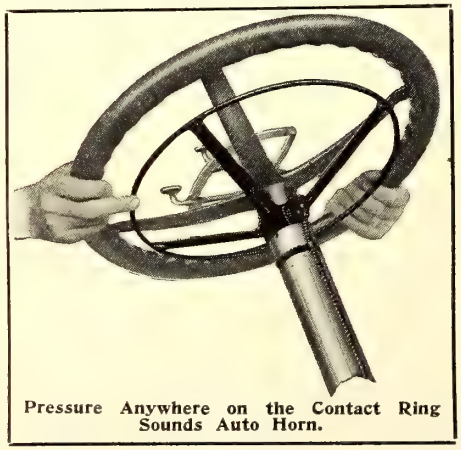
INSTITUTE OF RADIO ENGINEERS MEETING.

At the last meeting of the Institute of Radio Engineers before closing for the summer holidays and held on June 9 at Columbia University, New York City, two excellent papers were read as follows:

"Engineering Precautions in Radio Installations," by Mr. Robert H. Marriott, B. Sc., and the second paper was entitled "Static Elimination—Some Suggested Methods," by Prof. Dr. Alfred Norton Goldsmith, of the College of the City of New York Radio Laboratory.

Both of these papers were well received and contained some new and vitally interesting points on radio matters.

Mr. Marriott's paper dealt at length with the proper installation of all wiring on shipboard for radio sets, such as grounding or iron pipes containing wires and the grounding of all auxiliary metal parts in some cases. It was recommended that all metal members on the vessel be grounded, especially when powder or highly combustible or inflammable materials were to be carried. He explained at length that practical tests had shown that sparks would be produced between various metal parts on the ship and other metal parts, which latter might be grounded, or even between two insulated metal parts. In some cases even the rails around the decks have become charged by induced radio currents, and therefore all metal fittings should be well grounded to the metallic hull of the ship.



Prof. Goldsmith's discourse was rather hyper-scientific and quite difficult of practical demonstration or adaptation. It related to shielded aerial wires, etc.

Some interesting discussion was indulged in by those present, and Prof. Ferdinand Braun, of Germany, the famous radio authority, took an active part in same, as did also Mr. Weigant, designing engineer of the Marconi company.

IMPROVED SIGNAL-HORN SWITCH FOR AUTOS.

The new Seng switch recently developed for operating electric signal horns on automobiles, and shown in our illustration, possesses considerable merit, it seems, as no matter at what point of the steering wheel the hands grip same, it is always possible to operate the electric horn by just touching the "complete" contacting ring, which is shown mounted below the steering wheel proper.

German silver contacts are used in the make-up of this special switch and it should find a wide application among motor car owners and drivers of same.

Pressure Anywhere on the Contact Ring Sounds Auto Horn.

The switch is so made that it can be attached in a few moments' time to any steering wheel head, and it is provided with a length of flexible conductor with substantial insulated covering on same.

ELECTRIC HOUSE WIRING TROUBLES.

By W. F. Bennington.

PROPERLY installed electrical apparatus is the safest and healthiest means of providing heating and illumination. If improperly installed, however, it often becomes a source of extreme danger. The rules which govern the installation of electrical apparatus in this country are issued by the National Board of Fire Underwriters and are exceedingly rigid. To the average man they seem extreme. The matter of safety depends to a great extent on the honesty of the electrical contractor in properly installing the wiring and apparatus in accordance with rules of the above board. To receive the approval of the National Board of Fire Underwriters any electrical apparatus must pass a series of rigid tests before the approval is granted to the manufacturer. Wire is put through an exceptionally rigid test for insulating properties. Although the use of "approved" apparatus and wire may help to prevent trouble, the greatest source of danger lies with the electrical contractor and the help that he employs. A carelessly installed wiring system will sooner or later cause trouble and necessitate endless repairs and annoyance.

Perhaps the greatest source of trouble is *loose connections,* which cause heating and eventually the destruction of the connection itself. The heat from a loose connection will start any woodwork smouldering that is in contact with it. As a general rule these connections are out of sight and the trouble may continue for weeks without giving any warning. Suddenly there is one of those fires that seem to start from nowhere and are due to the fact that some careless workman neglected to tighten a screw or left a joint poorly soldered. Very often, however, a loose connection will give evidence of its existence by the flickering of the lights. This should have immediate attention, as it is sure to mean that something is the matter. As a general rule people blame the lighting company and talk about "inefficient service." Sometimes this is the cause, but don't take chances—find out. Turn on all the lights in the room and see if they flicker. If they do turn on all in the house and see if they are affected in the same way. If you find that one room alone is affected go to the distribution box and see if the fuses that control that room or part of the house are loose and tighten them up if necessary.

Loose fuses are often the cause of flickering lights. Should you find that all lights in the house are flickering and that the connections to the service are all tight, then call up the lighting company and tell them about it. If the trouble seems to affect only one room or part of the house and you cannot locate any loose connections or fuses, call in an experienced electrician and your troubles will soon be past. Make yourself familiar with your lighting system and know just where the fuses for each part of the house are situated and also keep a supply of spare fuses handy. This will save you a large amount of trouble and inconvenience, as it is unnecessary to call in an electrician every time there is a fuse blown. A few moments' explanation by a man familiar with house wiring and you can install your own fuses.

Don't overfuse your circuits. If a circuit is intended to carry a current of 10 amperes, don't put 30-ampere fuses in. The fuse is similar to the safety valve on a steam boiler, and putting 30-ampere fuses where 10-ampere should be is exactly the same as setting the safety valve of a boiler at three times the pressure that the boiler will safely carry. By putting in fuses of a

higher capacity than the circuit is wired for you stand an excellent chance of causing trouble that will be expensive to repair.

We come now to one of the most common troubles and one that is little understood by those not familiar with electricity. A copper wire will carry only a limited amount of current with safety. Should you exceed this amount the wire will begin to warm up, and the more current you cause it to carry the greater the rise in temperature, until finally it will come to the melting point and "blow out." Overloaded wires are the cause of many fires that "cannot be accounted for." The permissible amount of current for a wire of any size is determined by the regulations of the National Board of Fire Underwriters and should never be exceeded without special permission. This is a subject for the electrician to determine. The capacity of your wiring should be sufficient to carry all that you would be likely to use and also to allow for any future additions that you might wish to add. The trouble comes when Mrs. Smith or Mrs. Jones buys some of the modern electric heating devices, such as flat irons, toasters, percolators, etc., brings them home and screws them on the socket. If the circuit is fused just enough to carry the lighting circuit of that room the addition of the new device will blow out the fuse if the current it takes is in excess of the fuse capacity. Perhaps the fuse capacity is too large, and then she may add one thing after another until the wires are carrying more than they can stand and then they will "blow open" or overheat and cause a fire. The best way is not to take chances, but when you wish to install some of the new heating devices call up the electric company and have them look the circuit over.

And now a few words regarding "shocks." The average lighting circuit is about 110 volts, and one might almost say harmless as far as injury from a shock is concerned. All apparatus made to-day for home use is carefully insulated and the danger of receiving a shock slight, but this does not mean that little Willie can take a screwdriver and try to dissect the anatomy of your table lamp. He will not be injured by the shock, but it is almost certain that he will give himself a nice burn and in all probability spoil the lamp, if not the fittings to which it is attached. This applies not only to lamps and sockets, but to electrical apparatus in general.

My advice to any man who does not understand his lighting system is to let it alone. Your effort to avoid a bill from the electrician may result in burned fingers and spoiled apparatus. Call the man who knows just what he is doing, and the chances are that the trouble is small if your house has been properly wired. Let it alone—it pays.

Porcelain sockets should be used in any place where there is a chance of moisture, or where people are likely to get into contact with the ground. The "ground" means water or steam pipes or any metal that is connected to the earth. Bathrooms and cellars are places where porcelain sockets should be used—the bathroom especially, as there people often stand in their bare feet, with wet hands, and water is an excellent conductor. Death has been known to result from turning on an electric light while in the bath, though deaths from the average lighting circuit are very rare indeed.

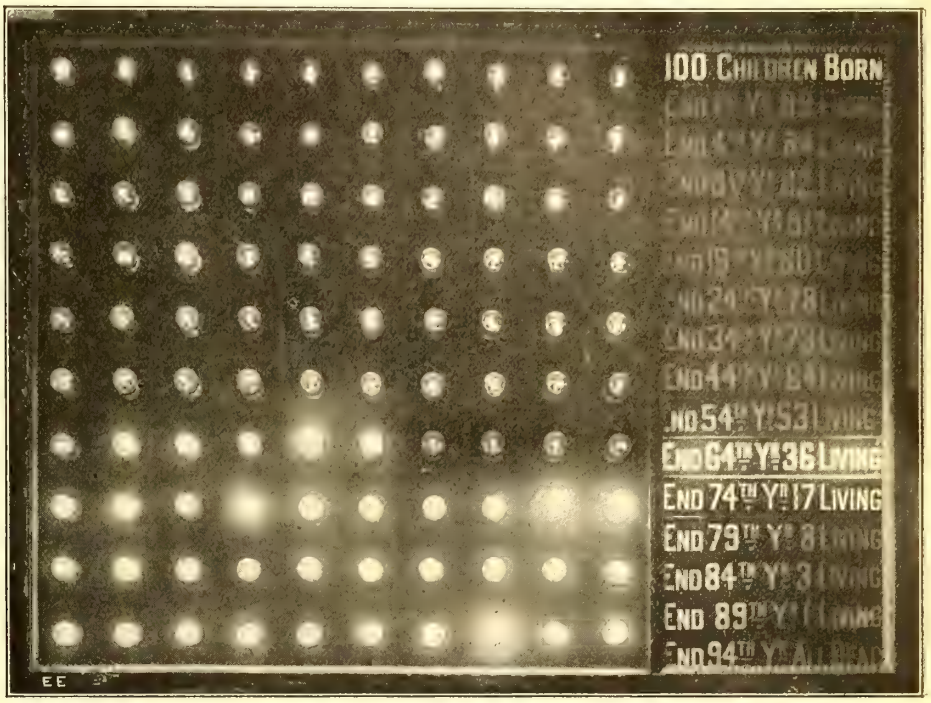
Familiarize yourself with your lighting circuit, observe the above suggestions and you are sure to save time, trouble and expense. There is no mystery about house wiring or apparatus. Spend an hour or so with your electrician, let him explain to you how it works and you will find it an excellent investment. Remember! Safety first.

ELECTRIC CHART TELLS PERCENTAGE OF DEATHS IN NEW YORK CITY.

It is pointed out that of every hundred children born in New York City 11 die within a year, in a recent number of the *Edison Monthly* magazine, and only one attains the age of 90. The city no longer produces centenarians.

A short time ago the Department of Health conducted a statistical study of the ages of the persons dying in New York. This detailed study covered a period of 13 years and involved 225,000 deaths, the figures here quoted being based on this record.

In the illustration is seen the novel method employed to graphically show the rise and decline of the population in the city. This electrical lamp-board is exhibited at the department's museum on Centre street, in the metropolis. In all, there are 100 incandescent electric lamps mounted on the lamp-board, in rows of 10. A specially arranged automatic flasher lights all of the lamps first; then at intervals of several seconds the flasher extinguishes the lights, until the chart, in a very striking manner, shows that all have died before reaching the age of 94.



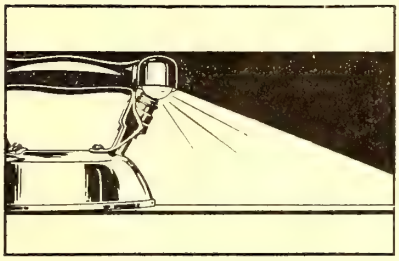


Photo Courtesy of New York Edison Co.

Electric Lamp Chart Depicts in Graphic Manner Mortality of a Great City.

This idea can very well be applied to many other branches of city departments, or also in many industrial corporation offices where records are to be studied by a number of interested people simultaneously. Besides, this method has a very striking effect, not made posible by any other means of indication.

ELECTRIC IRON CARRIES HEADLIGHT.

An electric iron with a feature that is entirely new has recently been developed by a Pittsburgh concern. This feature is a small *Mazda* lamp attached to the iron in front of the handle. On account of the presence of this lamp, the iron has been named the "Hedlite Iron." Due to the fact that the lamp is only a few inches above the surface to be lighted, it gives more light upon the ironing board than would be obtained from several large lamps located in a ceiling fixture.

Electric Sad-Iron Carries a Head Light.

The lamp is provided with a metal reflector, which has a shield to keep the light from striking the eyes of the operator, both when ironing and when the iron is at rest in a vertical position. The lamp socket is supported by the front handle bracket and the supply wires from the lamp are carried through a metal tube to the interior of the iron.

The lamp burns whenever the current flows through the iron and thus acts as a warning signal if the current has been left on by mistake. The current consumption of the lamp and iron is 500 watts. The iron is made in both tilting and stand types. The lamp is especially desirable and efficacious where there is only one outlet, as is frequently the case in apartments and small dwellings.

LIGHTNING RODS REDUCE PROPERTY DAMAGE.

In the annual report of W. E. Longley, State Fire Marshal of Indiana, attention is called to the fact that, as a result of the increasing use of lightning rods on farm buildings, only 453 cases of lightning damage were reported in Indiana during 1914, compared with 1,006 during the preceding year. "Lightning rods properly placed afford certain protection," declares the fire marshal, "for only seven buildings equipped with rods were struck during 1914. In these seven instances investigation showed that the rods either had gone a long time without proper attention or were not properly grounded."

Some Famous Electrical Laboratories.

PROBABLY there is no electrical concern who maintain a finer or greater variety of testing and research laboratories of every description than those of the General Electric Co., whose main plant is at Schenectady, N. Y., and who also maintain extensive plants at East Lynn, Mass., and several other cities.

The views shown herewith are those taken of some of the principal laboratories of this company at Schenectady. The portrait in the center of the group is a likeness of Dr. Charles P. Steinmetz, chief engineer of the General Electric Co.

eventually reach some satisfactory solution of their multifarious problems, thanks to the brilliant staff of specialists they maintain, and also to the extremely fine laboratory facilities afforded.

In Fig. 1 of the illustrations here presented is seen a section of the chemical laboratory, where all kinds of acids, salts, rare metals and oxides, etc., are kept ready for any kind of research work encountered. In the illustration at Fig. 2 is seen a corner of the special research laboratory, where various kinds of new lamps, vacuum bulbs, etc., are electrically tested out. A desk fan a million cycles per second or more.

Another view of one of the chemical laboratories is shown at Fig. 4, and here is observed also a set of electric ovens used for heating and other purposes. These electric ovens have rheostats located on the bench beneath them, so that the heat may be very finely regulated to any required temperature desired by the chemists.

Every modern appliance is at hand in these wonderful laboratories and they are probably the best equipped in the country to-day, if not in the world. No problem is given up until all of the research staff have

Several Views of the Wonderful Research Laboratories Maintained by the General Electric Co., at Schenectady. Center: Chief Engineer Dr. Charles P. Steinmetz.

This renowned engineer and scientist has associated with him some of the leading scientists and research workers of this country, and in this brilliant array appear the names of Irving Langmuir, Sol Dushman, Coolidge, and many others of whom perhaps we have not heard much in a popular way, but who are hard at work solving the many problems confronting such a vast corporation as this. Every imaginable kind of research work is done in these laboratories, including the fields of physics, mechanics, optics, all branches of electrical science, X-ray and incandescent lamps, chemistry, etc., ad infinitum. This will be the more impressed upon the reader's mind when it is said that the General Electric Co. never attempts to do a thing half way, but always goes to the bottom of any problem tackled. Also they, in most every case, may be observed mounted on a portable stool and blowing a draught of air on a special electric tube, noticeable just to the left of the "danger sign." A second tube of this type is also shown, illuminated, toward the left of the picture.

In Fig. 3 is depicted a section of the high voltage testing laboratory. Here extra high voltage insulators and insulating materials, etc., are tested for break-down strain or electrical resisting strength. Great care must be observed by those working in these high voltage laboratories and danger signs are kept posted, marked with proper warnings. X-ray tubes are tested out in this laboratory also. High voltage alternating and direct current is available for this class of work, and practically any voltage desired for tests here conducted is available at any frequency desired from 60 cycles up to half

had a try at it, and many marvelous inventions have been developed in these always busy "think factories."

TO LIGHT NIAGARA WITH SAN FRANCISCO EXPOSITION SCINTILLATORS.

A movement has been organized in the sister cities of Niagara Falls, N. Y., and Niagara Falls, Ont., to acquire the battery of electric searchlamps now being used for the scintillator illumination at the Panama-Pacific Exposition at San Francisco, and to provide for the electrical illumination of the Falls during a number of months of each year.

Are you a subscriber? Better decide now so you will not miss the many good things in the forthcoming September issue, 64 pp.

How Telephone Transmitters and Receivers Are Made

Do you know of the vast research work back of the telephone instrument you use daily? Telephony has grown to be one of the most highly specialized of applied sciences. How the separate parts of every instrument are exhaustively tested is explained in this article.

LITTLE does the average person, using the modest-looking telephone of to-day in its neat black dress, dream of the stupendous amount of money and engineering end of the game. We shall in this brief discourse endeavor to look into some of the more interesting aspects of the making of the telephone instruments. The

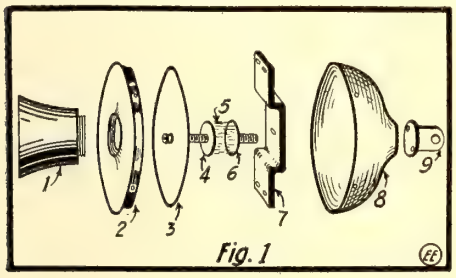

Fig. 1. Parts Making Up the Telephone Transmitter.

wonderful history of its inception and perfection have been well cared for in the extensive literature of the day and we will not take up the reader's time with such matters here, as space does not permit. Those interested would indeed do well to read Herbert N. Casson's wonderfully interesting treatise, "The Romance of the Telephone."

The Transmitter.

There are, of course, many different styles of telephones on the market, but as all are made up of essential parts, known as the *microphone,* into which we talk, and the *receiver,* which reproduces our speech, with more or less auxiliary attachments, we shall consider the most important parts, viz., the microphone and the receiver.

The "Bell" instruments used in this country are manufactured by the Western Electric Co., and as these have been simplified and standardized to a remarkable degree the greater part of the work here mentioned is that performed on "Bell" type sets.

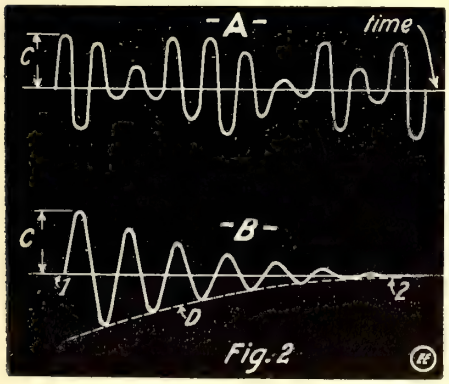

Fig. 2. At A, the Varying Voice Waves. At B, the Decay of Diafram Vibrations From Maximum Amplitude to Zero.

Take first the modern microphone, which picks up our spoken voice air waves and transforms them into undulating electrical currents, which are carried over the line to be retransformed into air or speech waves at the distant receiver. Its principal parts are observed in Fig. 1. The spoken voice sets up air waves which are projected into the mouthpiece and against a thin iron diaphragm 3, supported tightly all around its rubber-bound edge in the brass plate 2. The diaphragm 3 has secured at its center a small screw and nut, the inner end of the screw or stud carrying a polished carbon disc 4. A similar disc, carried by a metal bridge bar 7, forms the microphone chamber 5, which contains a small quantity of carbon grains. The transmitter parts being quite delicate, of course are contained in a strong punched-brass shell 8. A swivel or trunnion lug 9 is secured to the base of the shell, thus allowing it to swivel up or down in the manner we all know.

This will give a clear conception of the most important parts of the microphone, or transmitter, as it is termed. Each of the parts outlined and making up the complete instrument is the final result of vast technical research in the storehouse of Dame Nature.

The mouthpiece No. 1, for instance, although it looks very simple, has a history of its own. In the first telephone the mouthpiece was simply a hollowed-out portion on the wood front of the cabinet. Later a wooden funnel was introduced. This progressed through various stages of fibrous and hard-rubber composition, and some of the latest tried out were of glass and porcelain. Glass is very sanitary, but extremely fragile. Porcelain is still going through the test stage. "Condensite" is one of the newer synthetic compositions being tried out for the mouthpiece and possesses many good qualities, notably strength. It may be dropped on the floor without breaking. The mouthpiece is an important part indeed, and its shape and "sound" qualities are always going through research tests to find something better. That, in truth, may be taken as the slogan of the telephone specialist: "Something better." The search is everlasting and constant.

Consider the front plate of the case, or part No. 2. For many years this was composed invariably of a cast-brass or alloy plate. Now it was found, by observation and exhaustive trials, that it was practically impossible to produce a cast plate for this purpose which could be polished and nickel-plated, that would show up absolutely smooth and free from blemishes due to air or "blow-holes" in the casting.

Hence a staff of technicians were started to work on this problem, with the result that the plate is now made of a special bronze or brass alloy, made to a specified chemical formula and rolled in sheet form. The discs are blanked out in massive punch presses, electrically operated, and after passing through several punching and bending stages, we have the finished part ready for nickel-plating. Only a certain alloy will permit of the many and intricate bending and forming operations necessary to give it the proper shape. Sometimes a whole "lot" of sheeting cannot be used, owing to a slight difference in its chemical make-up, etc., causing it to crack while being punched and formed. Even the nickel-plate on the surface of it is scientifically investigated and the heaviest plating ever used is applied to give maximum "wear resistance."

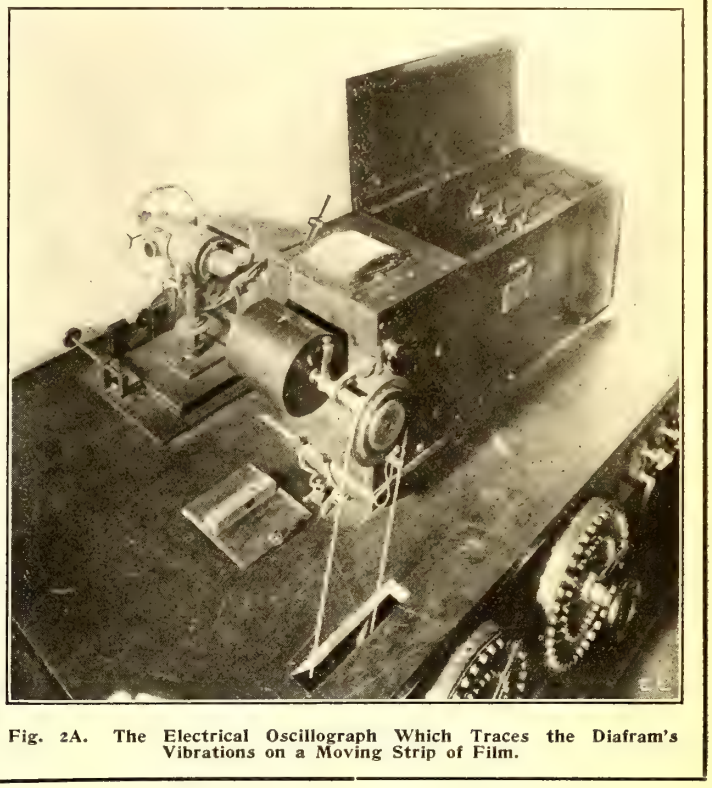

Fig. 2A. The Electrical Oscillograph Which Traces the Diafram's Vibrations on a Moving Strip of Film.

The diaphragm 3 is the part the average user of the telephone never sees, because it is hidden behind the plate 2 and perforated mouthpiece 1. This is one of the most closely studied parts in telephone science. Bell and Watson, in the early days, tried out all sizes and thicknesses of diaphragms, and the research in this direction has gone on ever since. The transmitter diaphragm need not be magnetic in character, and many different materials have been exhaustively experimented with, such as mica, gold-beaters' skin, fiber, brass, etc.

The present "Bell" diaphragm is made of a certain quality sheet iron, the thick-

ness being specified in thousandths of an inch, as well as its chemical constitution. To prevent rusting, they are treated in various ways. Some of these methods consist of "Sherardizing," electro-deposits of zinc, coating with Japan enamel, etc.

This covers some of the physical sides of the problem. When the finished dia-

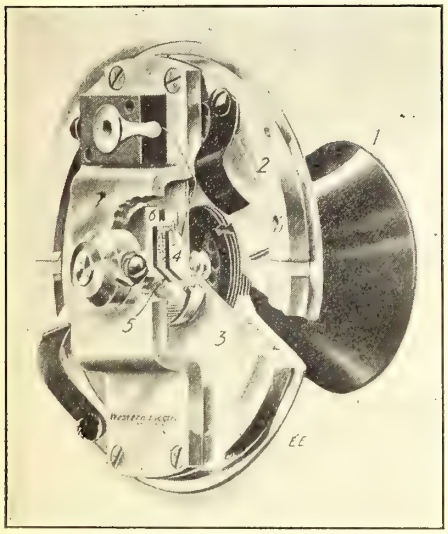

Fig. 3. Assembled View of Telephone Transmitter, Showing Carbon Grains, Etc.

phragm is ready for the electrical laboratory it undergoes a thorough and relentless test for various properties such as its elasticity and ability to follow faithfully the voice-wave undulations or vibrations. The voice waves are of many forms and frequencies and it is very important that a microphone diaphragm shall be able to pick up all the more important "speech-component" frequencies in the great numbers of complicated wave forms occurring in the average voice.

For the study of the diaphragm's vibrations an electrical oscillograph is utilized. This device records the vibration characteristics of the diaphragm when used for "speech" functions and also the time-period of its decay to a neutral or zero-vibration period after it has vibrated to maximum amplitude. Oscillograms of these vibrations are depicted at Fig. 2. The upper set of waves or ripples "A" are those of voice vibration, while the lower waves "B" show how the diaphragm's natural vibrations decrease from a state of maximum amplitude or vibration "C" at 1, to a zero vibration point at 2.

The balance of the microphone comprises, electrically, the carbon grains 5

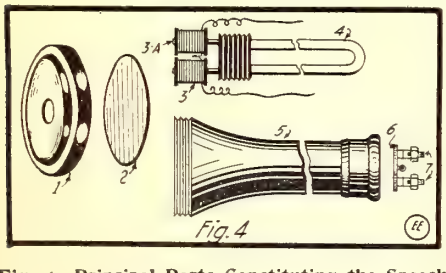

Fig. 4. Principal Parts Constituting the Speech Reproducer or Receiver.

(Fig. 1) and two carbon discs 4 and 6. The carbon used for this purpose is made in a special laboratory devoted to the purpose. Special furnaces are installed and all kinds of temperature and other measurements are taken while the grains and discs are being fired and annealed. The carbon mixture is the closest-grained product ever perfected and is susceptible of taking on a very high polish.

The grains are quite small, but regular in size and quality. The discs 4 and 6 are secured firmly to the brass sub-discs and supporting studs for attachment to the metal shell members. The carbon disc faces are polished like a mirror in specially designed rotary polishing machines driven by electric motors. Each machine will polish a great number of discs in a short time, owing to the unique arrangement of the machines. It may be remarked that mostly girls are employed in making up the parts, and especially in the assembly department.

The complete transmitter is illustrated at Fig. 3, and behind that innocent-looking little device is a battery of the foremost scientists in the electrical and mechanical realm, still banging away at the problem of "something better."

The Telephone Receiver.

The receiver on the telephone we use has, oddly enough, remained about the same as Alexander Graham Bell's original

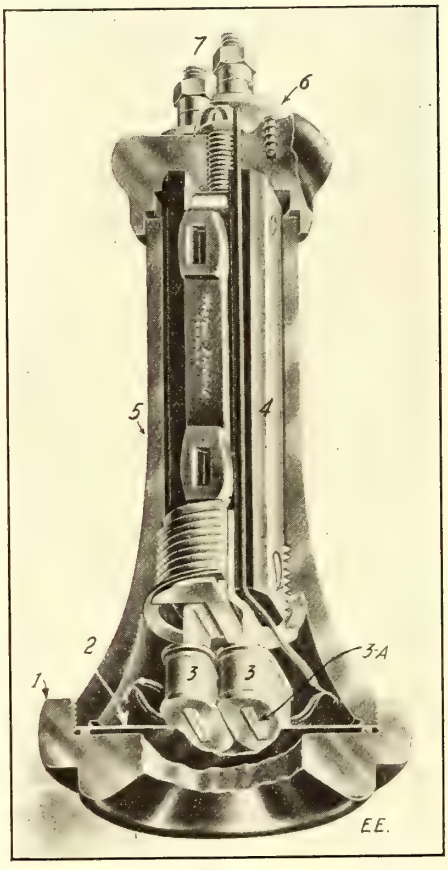

Fig. 5. Assembled (Sectional) View of Telephone Receiver. Standard Long-Distance "Bell" Style.

instrument—a remarkable tribute to the basic soundness of his theories and early instrument. If his original instrument had not been right to an almost infinite degree it would scarcely have lived through the first few years of its existence, which it did in the face of the most stupendous patent-suit litigation this country has probably ever witnessed. Inventors by the hundred sprang up, like mushrooms over night, claiming that they had prior patent rights on a speaking telephone similar or superior to Bell's patents. He finally won out in the highest court in the land, however, and the telephone got started on its way.

To proceed, the standard forms of the telephone receivers are the "Bell" commercial long type and the watch-case receiver, resembling a watch in size. The illustration (Fig. 4) shows the principal parts of the long receiver, and Fig. 5 shows the complete assembled receiver.

(To be concluded.)

OUR SUPPLEMENT

GUGLIELMO MARCONI, D.Sc., the subject of our supplement this month, is undoubtedly the acknowledged pioneer in wireless telegraphy, as we know it to-day. He it was who, by his persistent experiments and studies at the Leghorn Technical School in Italy, made possible signaling without wires over marvelous distances by means of electro-magnetic waves properly set up and propagated through the ether which, so far as we know, pervades and fills up all interstellar space, both inside and outside of our planet, the Earth.

Signor Marconi, of Italian parentage, was born at Bologna, in Italy, in the year 1874. He is therefore a comparatively young man and more zealous than ever in his endeavors to improve and perfect the art of wireless telegraphy and the apparatus pertaining thereto.

We probably are all familiar with the early history of wireless, dating from the time of Marconi's successful tests conducted at his father's estate at the Villa Griffone, near Bologna, which tests and experiments were conducted in June, 1895. Shortly thereafter it became possible for him to cause a receiving instrument to be actuated by wireless waves over distances of one and one-half miles, using poles to support large tin sheets connected with wires, and which poles were but 25 feet in height.

These early experiments were carried on principally with a small spark coil provided with ball spark gap, and for the receptor a Branly metal filings coherer was used. Marconi improved this coherer wonderfully, so as to make it reliable and sensitive to the very minute Hertzian wave currents propagated through the ether from the spark at his transmitting station.

Shortly after the successful tests in Italy, or in July, 1896, to be exact, he went to England and there introduced his remarkable invention to Sir William Preece. Marconi had already applied for a British patent during the preceding June and Preece was very favorably struck with the Italian's invention. By 1897 it was possible to transmit and receive wireless signals and messages by these methods over distances of nine miles between Penarth and Brean Down, across the Bristol Channel. On the Salisbury plain he covered distances of four miles and more overland, employing in these tests a 6-inch spark coil for distances up to four miles, but a 20-inch spark coil was used at different times in tests conducted over greater distances. Also large kites were employed from time to time to elevate a fine aerial conductor, and good results were obtained with this method. Some of the first transatlantic wireless signals in the form of that immortal letter "S," comprising three dots in the Morse code, were received by the aid of kites flying at a high altitude.

In the first few years of wireless many installations were made on various ships of the English and Italian navies, etc., and one of the first important applications made of the new Marconi wireless system was to establish communication between the King of England's yacht and a shore station.

To-day the Marconi system is the largest and most comprehensive extant, and distances of 3,000 to 4,000 miles have been covered repeatedly.

The world owes a debt to Dr. Marconi which cannot be overestimated, and his name is sure to ring down through the ages as the real inventor of practical, commercial wireless transmission of intelligence.

An Interview With Guglielmo Marconi

By Samuel Cohen

WHAT a wealth of meaning there is to the two words, "Marconi" and "wireless" to practically every educated person to-day! Undoubtedly for many years to come the name of Commendatore Guglielmo Marconi will be famous throughout the world and known in practically every household as that of one of the greatest benefactors of the age and as the pioneer inventor and perfecter of wireless telegraphy, as we know it to-day.

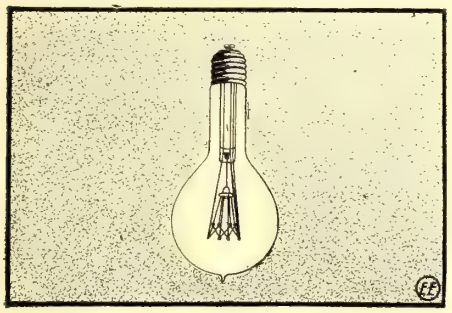
Dr. Marconi is well past middle age and looks in the best of health. He is rather tall and well set up, marking him, you perceive, a military man in more aspects than one. This is due, in a great measure, to the fact that he is a Lieutenant in the Italian Navy. He bears his 41 years well, indicating an uncommonly strong mind and body.

As the wireless telephone is one of the latest and most misunderstood apparatus, perhaps, of the present time, I asked him how this matter was progressing. Mr. Marconi stated that there was great hope for the future and, in fact, in the very near future, of greatly extending the range of wireless telephony. "It is being used on practically all warships of the Italian Navy," he stated, "and is being employed to a considerable extent in the British and other navies. Apparatus of the Arc and other types are being used and thoroughly tried out for this purpose, and the best grade sets, such as used in the Italian Navy, can transmit the spoken voice over distances up to 100 miles and more, which is very good, of course, considering that on shipboard it is difficult to erect a very large antenna. One of the later developments in wireless telephone apparatus is that making use of a modification of the well-known *Fleming Valve*. By suitably combining an oscillatory circuit around this valve and also by means of other super-imposing circuits containing the microphones, we have made it possible to talk over quite considerable distances by this very simple and sure means. It is more stable and certain in its character by far than the Arc type of apparatus, generally speaking."

"These wireless telephone sets are provided with a simple switch by which the operator can change over from transmitting to receiving speech very quickly, and they are operated by means of an 80 ampere-hour storage battery which heats the vacuum valve filaments and also a 500 volt current is provided for actuating the trigger control circuit of the valve, as it is called."

"This current is produced by dry batteries, and these sets are not limited to the transmission of wireless telephone speech, but can very easily be converted into wireless telegraph transmitting sets by the substitution of a Morse key in the circuit, etc. These vacuum tube transmitters are able to work over ranges up to about 35 miles thus far."

I asked Dr. Marconi about the other forms of wireless telephone apparatus or undamped wave type generators, etc. He intimated that a great deal of experimental and research work was being carried out in England and in some of the other Marconi laboratories on the multiple spark frequency wireless generator which can produce practically undamped waves by allowing several different sparks in the circuit to jump the gaps at slightly different periods. In this way there are not any long breaks between the sparks and the ordinary dead-time period between sparks of the common radio transmitter, are filled up with the waves from other sparks synchronously and critically timed.



One of the latest branches of science Dr. Marconi is intensely interested in is that of seeing over a wire by electricity. He mentioned that a considerable amount of research work has been done in transmitting images by wireless and successful results were already obtained. Dr. Marconi is quite sure that the time will soon come when one will be able to see a friend in Europe by means of wireless television and at the same time speak to him.

Regarding the powerful and recently completed trans-Atlantic radio stations in England and the United States Dr. Marconi is hopeful the European war will soon cease so that these stations can be put into regular operation. These are at present tied up for the reason stated and particularly as the British Government has taken over the control of the Wales stations for official work of the War Department.

Before departing I suggested to Dr. Marconi that thousands of young experimenters in this country would highly welcome a picture of himself to adorn their dens and laboratories. Dr. Marconi then graciously autographed a photograph for the especial benefit of the readers of *The Electrical Experimenter*. It is this photograph which forms a supplement to this number.

NEW DOUBLE-FILAMENT GAS-FILLED LAMP.

A "two-in-one" incandescent lamp, as it is called, has recently been put on the market and it should find a wide sale. The filament is made in two sections, one of which can be operated while the other is out of service, or both may be burned at the same time. Thus, if the lamp is rated at 200 watts, each side takes 100 watts. Either or both sections are placed in circuit

Latest Double Filament Gas-Filled Incandescent Lamp.

by a screw attachment in the base. The lamp is filled with nitrogen, argon and other gases. The specific consumption, the manufacturer asserts, is 0.6 watt per C.P. or less. The average life with the filament sections burning separately is 2,000 hours, and with both burning together 1,000 hours.

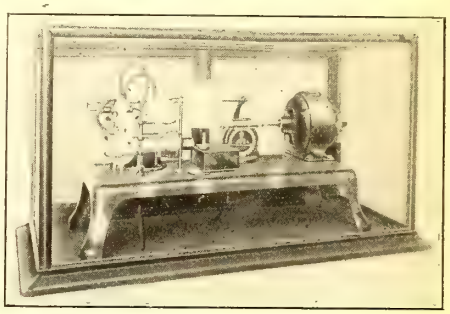
ELECTRIC SMOKE RECORDER.

By Frank C. Perkins.

The accompanying illustration shows a novel and interesting smoke recorder, electric motor driven, as recently developed at Chicago, Ill. It is held that war was declared against the smoke nuisance in the reign of Queen Elizabeth and has been going on ever since.

The problem therefore is to find the means of making the careless and negligent fireman careful. It is in the nature of every man to be more attentive to business when he is under inspection.

Recording apparatus of every kind is coming more and more into use, particularly in power plants. It is maintained that the most effective remedy for the smoke nusiance that has ever been produced is the smoke recorder. It proves itself if one admits that careless firing is the one great cause of smoke, because the smoke recorder is a check, both upon the chimney and the fireman. Smoke can always be greatly reduced and sometimes completely eliminated by careful management of the fires. No matter what kind of "smokeless furnace" one may have, it cannot live up to its title and make steam unless it is managed with care and intelligence.



This new electric-driven smoke recorder originated in the brain of Ray L. Eddy, who has devoted many years to the study of smoke, its causes, effects and remedies.

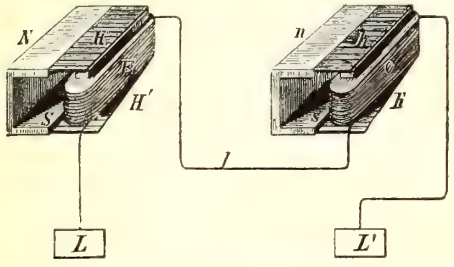
This electric recorder is the "watchman" that informs the fireman immediately if the stack begins smoking. He can at once adjust the dampers or apply any other remedy that is recommended by this observation and experience. He can stop smoke within the time limit named by the city ordinances, and in all probability before a smoke inspector or some complaining citizen can get his eyes upon the chimney.

In order to fight smoke it is necessary to know what causes it. Smoke is usually caused by lack of air, improper mixture of the air with the gases or lack of temperature. Improper furnace design often has much to do with it.

The electric smoke recorder is built like a watch and, entering into the theory of the principles involved in the smoke recorder, it may be stated that if one drives a jet of smoke against porous paper the soot and other coloring matter will adhere to the paper and form a permanent record. It will be permanent because the soot particles will be driven into the pores of the paper. The record upon the paper will correspond with the color of the smoke, irrespective of what that color may be.

There are two things necessary in the

Electrically Operated Smoke Recorder.



construction of a smoke recording apparatus. To provide means to draw a sample of the gas from the stack and force it through a small orifice and also to provide a sheet of the proper paper and a clock or other mechanism to move it. Reduced to its primary elements, a smoke recorder consists of a pump and a clock and a piece of paper.

It may be stated that the chart is sectionally ruled in hours and minutes, each chart covering a period in excess of 12 hours, and one can tell almost to the second when the chimney began to smoke and also when the fireman stopped it by proper firing.

THE BIRTH OF THE TELEPHONE.

An extremely interesting lecture on the birth and babyhood of the telephone was presented by Bell's former co-worker, Thomas A. Watson, before the New York Electrical Society at a recent meeting.

He detailed in an interesting manner how the telephone had sprung from the musical telegraph, upon which he and Prof. Bell were engaged. Although Bell had the idea in his mind for two years, it was not until June, 1875, that a successful speech-producing instrument was made. The first idea on the propagation of music or speech over a wire by electrical means was presented by accident. One of the musical telegraph reeds had stuck fast, and Mr. Watson said he plucked the reed several times. Prof. Bell at once came into the test room, demanding to know what Mr.

The Forerunner of the Telephone. Bell's Early Musical Telegraph.

Watson had done. Bell had heard the feeble undulatory magnetic impulses produced by the vibrating reed before its magnet and reproduced electrically over the short line in the musical receiver. Thus the germ was sown which laid the basis of the wonderful telephone system we have to-day.

The illustration here shown is of one of these early Bell musical telegraph systems, where a series of different-toned steel reeds currents in the coil E, which will pass through the wires l and ground L L' to the receiving coil H', mounted on a magnet also provided with tuned steel reeds in front of the coil. Thus a certain reed vibrating at the transmitter would set the "same tone reed" vibrating at the receiver. Multiplex telegraphy over one wire was the goal.

A replica of the first telephone used by Bell was shown and, of great interest also, the original wire used in the first half-mile telephone circuit ever erected by Mr. Watson in Boston. The wire was coiled on a small spool and preserved in a neat glass cabinet.

The first ringer for telephones was developed by Mr. Watson. For the first telephone installations the party was called by thumping the home diaphragm sharply with a pencil. This set up sharp sounds at the receiver end of the line and anyone near the instrument would hear the thumps, so to speak. Shortly after he invented the "Watson jingler," or polarized bell, operated by a magneto, and this device, like Bell's wonderful receiver, has practically remained the same in its design these 38 years past.

RUSSIAN DUMA GREETS ENGLISH COMMONS BY WIRELESS.

A new and powerful wireless station erected in Russia since the outbreak of the war transmitted the first messages to England recently in the form of a greeting from the Chairman of the Duma to the Right Honorable James W. Lowther, Speaker of the House of Commons. Mr. Lowther acknowledged the greeting by wireless.

TAPPING THE EARTH'S ELECTRICITY.

The latest suggestion of theoretic science is that inventive mankind will some day be able to tap the earth's electric supply. Everyone knows nowadays that the earth is, among other things, an enormous electric magnet and that as it twirls around eternally on its unseen axis its friction against the atmosphere creates a perfectly unlimited supply of electricity.

The British Royal Society claims that invention is already close on the track of perfecting a method by which this electricity can be collected from the atmosphere. If this can be done there will be no necessity for electric power plants.

Every factory will be equipped with an inexpensive machine that can absorb from the air electricity just as already there are machines that can absorb oxygen from water that costs little or nothing to collect.

The idea suggested is that some machine be created to suck down the earth's electric fluid. This is being done all the time by every tree, and it is this attractive force of tall trees that causes them to be so frequently struck by lightning during big thunder storms when the atmospheric electricity is present in enormous quantities.

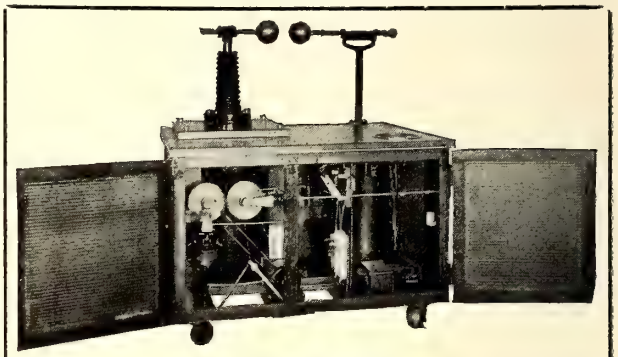
A machine for collecting atmospheric electricity, however, would not depend on electric storms for its sources of supply. The atmosphere is always filled with a silent, all-pervading but powerful electric current. It is this permanent current that it is suggested mankind will some day succeed in harnessing to the triumphant car of human progress. When it is done, the race will have easier and quicker traveling toward the final triumph of mind over matter.

MARCONI A VOLUNTEER.

William Marconi has asked that he be enrolled as lieutenant of engineers and assigned to duty with the telegraph brigade at Florence.

A NEW 3-VOLT DRY CELL.

Ordinary dry cells used for bell and ignition work give but 1½ volts each. All such cells are the same as regards voltage. Now we have the "Nitrogen" 3-volt dry battery, which should find a host of friends. It is exactly the same size as the standard No. 6 Columbia cell and can be interchanged in battery boxes, etc. It is composed of two cells placed end to end, thus producing 3 volts. Owing to a new substance used in making up these cells their efficiency is much greater than that of ordinary dry cells. The experimenter will find this 3-volt cell a great convenience indeed for operating small motors, spark coils, lighting lamps, etc. It costs but little more than the ordinary 1½-volt cell and marks a new epoch in dry cell manufacture.



TO GO THROUGH PANAMA CANAL SHIP NEEDS WIRELESS.

It is now unlawful for any passenger steamer, whether of American or foreign register, carrying 50 or more persons, including both passengers and crew, to leave the Canal Zone unless equipped with wireless telegraph apparatus capable of transmitting messages at least 100 miles and having a competent operator.

NEW HIGH-FREQUENCY MACHINE FOR TESTING INSULATORS.

It has long been known that when a lightning bolt or discharge strikes a transmission line carrying electric currents this high-frequency atmospheric current will affect the insulators on the line in a different manner than the ordinary current, no matter whether it is direct or alternating current at any commercial frequency, such as 60 cycles, etc.

Heretofore high-voltage insulators, such as used on the wonderful long-distance transmission lines such as those in the Western parts of the United States and Canada, have always been tested at 60 cycles frequency for several times the voltage to which they were to be subjected in their regular duty on the line.

125,000 Volt High Frequency Oscillator.

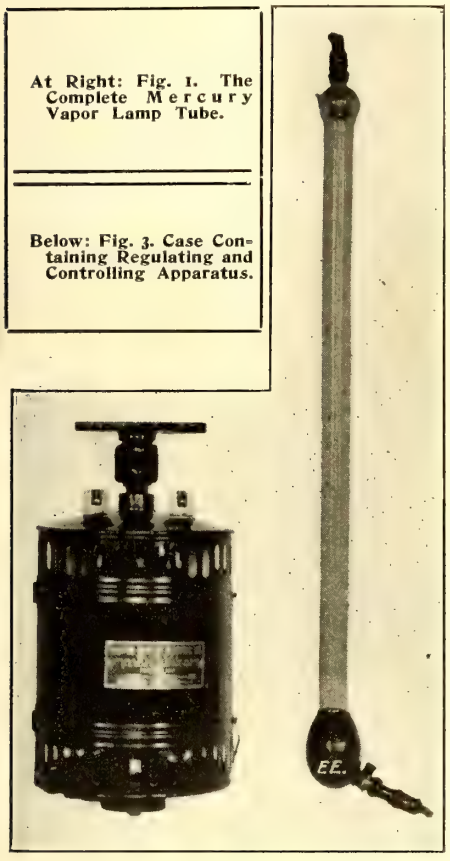
It was found, however, that very frequently these insulators would fail for some apparently unknown reason, and after much inspection and research work it was found that a lightning discharge, in view of the fact that it is of very high frequency and similar to a wireless discharge, would strike right through the insulator and put it out of commission for further service. This happened many times where it was self-evident that the transmission line voltage could not have done any such damage.

One of the latest machines for testing these insulators under such lightning discharge conditions is shown in the illustration, and it is built by the General Electric Co.

It is designed and furnished, when desired, for use on any commercial frequency circuit, and utilizes about 2½ K.V.A. at 60 cycles on 110-volt A. C. circuit. It can produce very high frequency currents, running in value as high as 300,000 cycles per second at a potential up to 165,000 volts. Special forms of this machine are furnished, when necessary, giving as high as 500,000 volts. Hence the advance of the engineer continues in his decision to hold his own with the forces of nature.

ELECTRIC POCKET LAMPS FOR THE ARTILLERY.

Among the goods recently bought in the United States for use abroad by soldiers in the fighting zones were 5,000,000 electric pocket lamps. The demand for these lamps is due to the fact that on land the war has in large part become a long-range artillery duel, the other branches of the service meanwhile seeking protection from bursting shrapnel by living in covered trenches. In these trenches, as well as in the air, on the sea, or under it, electric pocket lamps are ideal illuminants.



A Trip Through the Cooper-Hewitt Electric Works

By Theodore Hinchcliff

A trip through the Cooper Hewitt Electric Works brought to light two very interesting facts: First and most important, the advanced manufacturing processes involved in making the wonderful Cooper-Hewitt mercury vapor lamp, which is well known to our readers for its pleasant and efficient light, and second, its value in commercial applications. A. D. Child, of their sales staff, kindly conducted me through the various departments of the plant.

At Right: Fig. 1. The Complete Mercury Vapor Lamp Tube.

Below: Fig. 3. Case Containing Regulating and Controlling Apparatus.

The first step in the manufacture of the mercury tube (see Fig. 1) is the bulb, the tube comprising three glass pieces, A, B and C (Fig. 2), which are fused together. A small stem E is made on top of the large bulb B by heating that portion and blowing it out to the proper size. Another small glass tube E_1 is fused onto the tube E. This tube is used to connect the bulb B with the air-exhausting apparatus and for filling the tube with mercury.

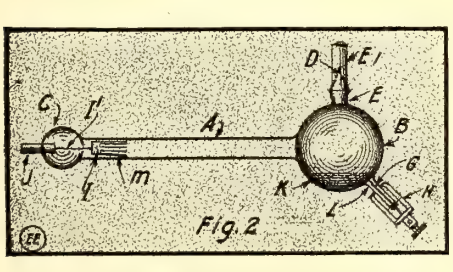


Fig. 2. Details of Mercury Vapor Tube.

The electrode G is now made and sealed in, which consists of a platinum wire sealed into the glass stem L, and is fastened to the connector H. The other electrode I is next sealed in. This electrode I consists of a cylinder of sheet iron with a small lap M for making contact with the mercury when the tube is tilted. The cylinder is joined to a small strip of platinum wire I^1, which is sealed into the bulb C and then connected with another terminal connector J.

After all these parts are made and skilfully placed in the tube the filling with metallic mercury K and exhaustion of the tube next takes place. The tube is brought to the mercury-filling department, where thousands of them are filled daily. The tube is connected by means of a rubber tube with the mercury chamber through the neck E, and a certain quantity of mercury is admitted, depending upon the size of the tube. Some tubes take six ounces, others 10 and 12 ounces. The tube being filled, it is now ready to be exhausted, and extreme care is taken in this process, as the *quality* of the tube depends entirely upon the exhausting. The tube is placed in a hot bath of air and connected with an exhaust pump, which is an ordinary mechanical exhaust pump. The connection is made through pipe E^1. While in the hot bath the mercury is boiled, thereby purifying it and also helping to drive out the air in the bulb. As soon as the operator sees that the exhaustion is complete he carefully seals the tube E_1 by heating it at point E until it melts, and gradually pulls it out to the form D as shown. Fig. 4 shows the exhausting laboratory. In this picture there is shown the apparatus where the mercury tubes are exhausted. A is an asbestos cylinder or shell in which the tube is placed while the air is being pumped out. B is a furnace producing a hot-air blast blowing into the chamber A. C represents the tube coming from the air pump located in the basement and connected to the glass tube. D denotes the mercury trap.

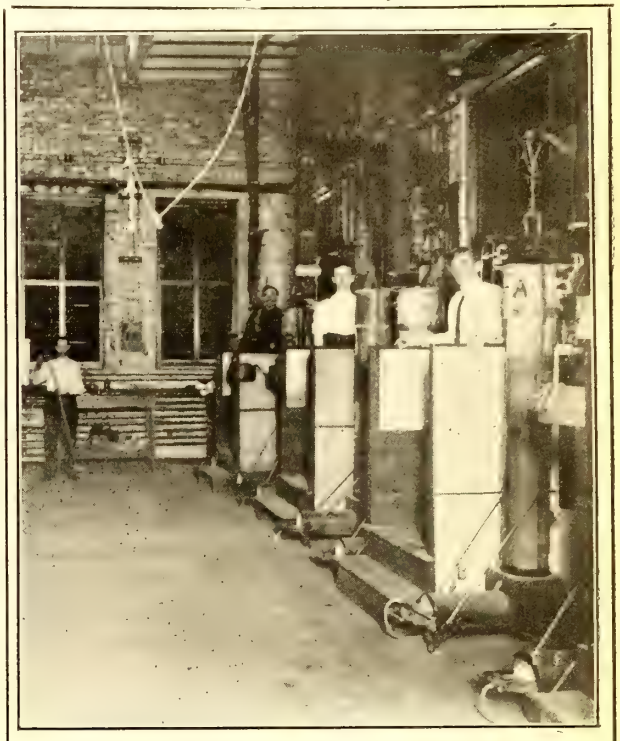

Fig. 4. Exhausting the Mercury Vapor Lamp Tubes.

The tubes are now finished and are brought to the testing room. Here each tube is carefully tested in every respect, both physically and electrically. They are first examined to see if they contain any mechanical defects. If so, they are placed aside and repaired, while the others are placed on a testing frame. Here they are kept for several hours while each tube is critically watched by experienced men. Every tube before being sent out is thoroughly tested, thereby assuring the consumer of a perfect product.

The tube is not the complete lamp, which includes a controlling device which momentarily tilts the tube automatically, while some tubes are self-starting. This is done by using a "kick apparatus," as it is termed technically. Various kinds of resistance and magnet coils are made in this plant for the mercury vapor lamps also.

The tube is placed in a suitable frame, which also contains the electro-magnets for tilting the tube. This frame is shown in Fig. 3, and it also contains the proper resistance coils. If it is an automatic tube the frame would contain the automatic devices for that particular tube.

The second important thing is the value of the mercury tube commercially, as it is very efficient for photography, drawing, etc. It also gives, in special forms, valuable effects on alternating current, the latter being perhaps more interesting to the general experimenter.

Everyone is acquainted with the glaring light which the ordinary electric lamp emits. It has a sort of blinding effect and it also produces many shadows, due to its concentrated center of light radiation. These effects are entirely overcome by the mercury tube, because the surface of the tube is large, therefore giving a greater diffusion of light, which is, of course, more pleasing and less tiring to the eye than the ordinary incandescent electric lamp. For this reason the Cooper Hewitt mercury tube is now being extensively adopted in factories, drafting rooms, etc., where the shadows are most troublesome. The rapid effect of the light of these tubes on photographic plates makes it extremely valuable for use in photography, especially in motion picture studios and in blue-printing.

Another peculiar feature of the mercury tube is in rectifying alternating current into direct current; this form of rectifier is widely employed in auto garages where alternating current is supplied and batteries are to be charged.

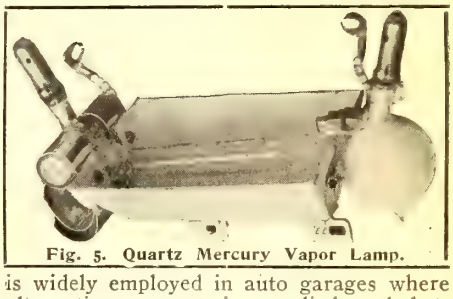

Fig. 5. Quartz Mercury Vapor Lamp.

One of the latest types of mercury tubes is the Quartz lamp, which is shown in Fig. 5. This tube works just the same as the

(*Continued on page* 151.)

A NEW HYDROGEN X-RAY TUBE.

By Frank C. Perkins.

The accompanying illustration, Fig. 1, and drawing Fig. 2 show the design of a unique hydrogen X-ray tube offered to Roentgenologists not as an experiment or a promise but as an actuality. It is claimed that the work with the hydrogen tube in several of the most prominent X-ray laboratories in America has substantiated in full the results in the Snook-Roentgen experimental laboratories on the new tube here shown.

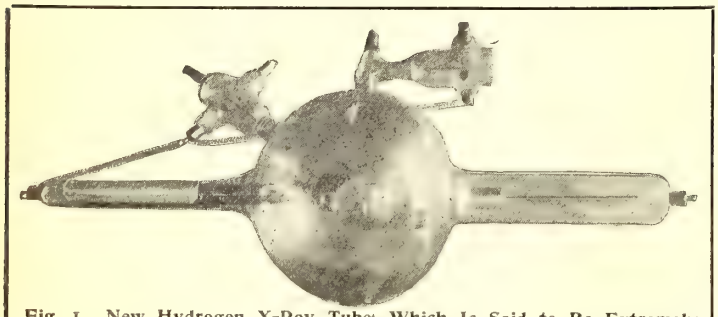

Fig. 1. New Hydrogen X-Ray Tube, Which Is Said to Be Extremely Efficient.

It may be stated that the pure hydrogen gas is the chemical means used for the regulation of the hydrogen X-ray tube. When the tube is to be lowered as to vacuum a current of approximately 25 milliamperes is discharged across a spark gap of about ⅛ inch long in a glass bulb containing chemically pure hydrogen. This spark heats to redness a metal osmotic tube. One end of the tub opens into the vacuum of the bulb proper (see Fig. 2), while the other is closed and prevents the hydrogen from entering the vacuum except when the metal, heated to redness, acts temporarily as an osmotic membrane.

The amount of hydrogen admitted to the vacuum is determined by the length of time the metal tube is kept red hot (and also by the temperature of the osmotic tube). The rate of diffusion through the metal increases with the rise in temperature, care being taken not to melt the metal. Hydrogen gas actually comes out of the tube when the vacuum is "raised," due to its own osmotic pressure, since ordinary atmospheric air contains practically no hydrogen.

It is stated that for continuous, heavy work no tube ever designed has given results equal to the *air-cooled* type of hydrogen tube. Compressed air, at about 4 pounds pressure, is used as a cooling medium for the air-cooled hydrogen tube. Both the anode and cathode are hollow almost their entire lengths to deliver the air to the inner extremities, as perceived from the cut.

The air delivered to the cathode serves also to cool the main glass bulb, as illustrated in Fig. 2. The vacuum control of the air-cooled hydrogen tube is identically the same as that of the standard type of hydrogen tube. The air supply necessary for operating the air-cooled hydrogen tube can be readily obtained from the compressed-air service of many hospitals and office buildings by merely connecting with the piping and installing a pressure-reducing valve. When this is not available a direct-connected motor and air compressor can be installed of the right capacity to care for the simultaneous cooling of two tubes.

It is claimed that results from day-by-day use of the hydrogen tube in X-ray laboratories over a period of many months have demonstrated that it will accomplish from three to five times more than any ordinary tube—in duration of service and in efficiency. Both in initial investment and in repair items a real economy is effected, and the more uniform operating characteristics of the tube give uniformly better results and radiographs that are uniformly good, while tests have proven that the focus point is very steady and does not wander.

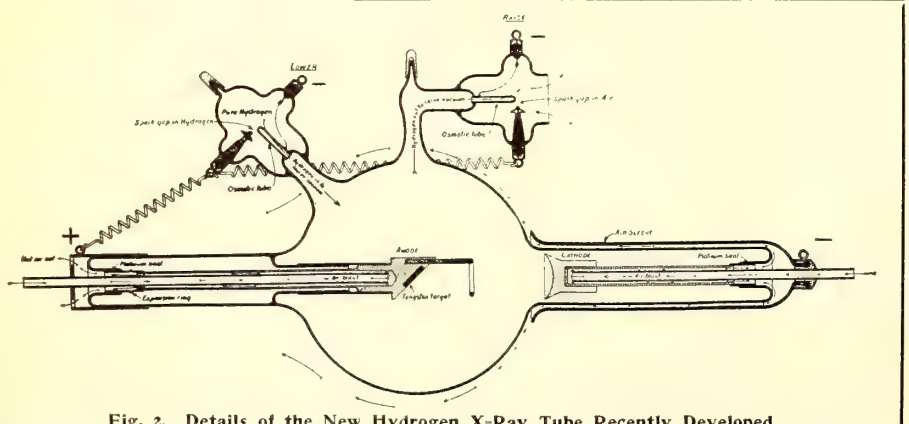

Fig. 2. Details of the New Hydrogen X-Ray Tube Recently Developed.

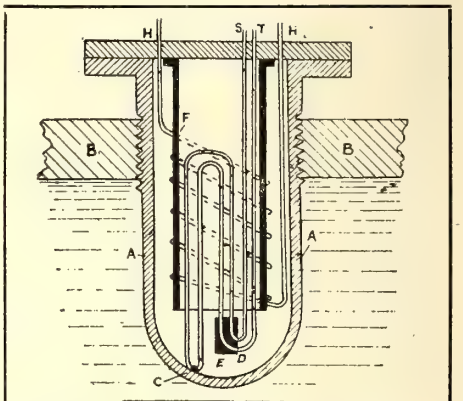

WIRELESS IN COURT.

Judge Mayer sat recently in the Federal District Court of New York City and listened to the wireless messages which were passing between vessels at sea and the land stations at Sayville, L. I., and Sea Girt, N. J. The apparatus, which had been set up in his courtroom, was erected to help him decide a patent infringement suit, brought by Samuel L. Kintner, receiver of the National Electric Signaling Co. against the Atlantic Communication Co.

The suit, which is highly technical, turns largely upon what experts call a "high frequency musical tone." It is alleged that the Atlantic Communication Co., in producing this tone by means of apparatus which has been made under the Telefunken or German patent, is infringing on the apparatus covered by the Fessenden patent, which belongs to the National company.

FEELING FOR ICEBERGS ELECTRICALLY.

It was after the disaster of the *Titanic*, when inventors realized the importance of an instrument which would notify the navigating officer of some approaching iceberg. Many different devices were invented for this purpose, and one of these is herewith described, its action depending upon the thermo-couple or electric thermometer principle.

Electrical Device Tells the Approach of Icebergs.

Looking at the accompanying sketch, a "thermo-couple" ST is mounted inside a metal capsule A, which is screwed through the ship's hull plate B. One junction C of the "thermo-couple" is soldered onto the shell A, and hence rapidly assumes the same temperature as the water outside. The second junction D, however, is imbedded in a block of material E, which permits it to assume slowly the temperature of the air inside A. The free ends of the wires ST are connected to a sensitive relay; the wire HH is wound around the insulating tube F and serves for heating purposes. At ordinary times the contacts CD are both at the same temperature, hence no current flows through ST and no alarm is given. But when an iceberg is approached the temperature of the water varies repidly and the junction C is cooled much more quickly than the junction D. As a result a "thermo-electric" current is set up, and this operates the relay, which in turn closes an alarm circuit and warns the navigating officer of the impending danger.

A NEW VEST POCKET AMMETER.

A novel, compact type of pocket ammeter has been developed by the Benford Manufacturing Co., of Mt. Vernon, N. Y. As perceived from the illustration of same, it is a metallic barrel, inside of which is a coil of magnet wire. When the tip on the flexible cord and the second tip on the base of the instrument are placed in contact with a source of current, such as a dry cell, the calibrated iron plunger in the center moves inward in proportion to the amount of current passing through the coil. The idea is old, but the make-up of the instrument as a whole makes it very serviceable and free from derangement.

The voice by telephone travels from New York to San Francisco in 1-15th of a second, traveling at the rate of 56,000 miles per second. The voice of a man speaking in New York is heard in San Francisco three hours earlier, that being the difference in the standard time of the two cities.

How to Build an Electric Writing Machine or Telautograph

By Homer Vanderbilt

THE telautograph is an electrical machine by which handwriting may be transmitted electrically over wires. Many articles have been published on the telautograph, but in these the interest of the novice has been rather neglected if he should want to build a simple electric writing machine. It is the object of this short article to show the experimenter, with drawings and general explanation, how to construct one.

The details for the construction of the

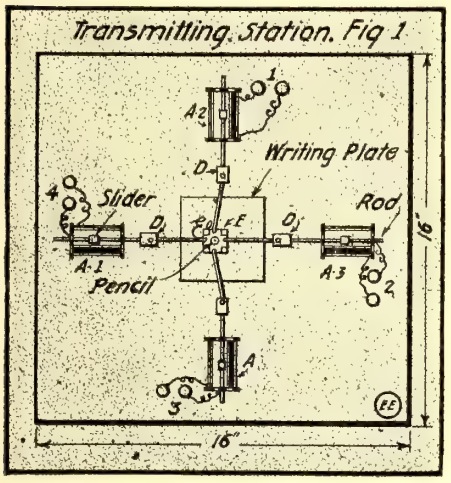

Fig. 1. Transmiting Apparatus for Sending Script Messages Over a Wire.

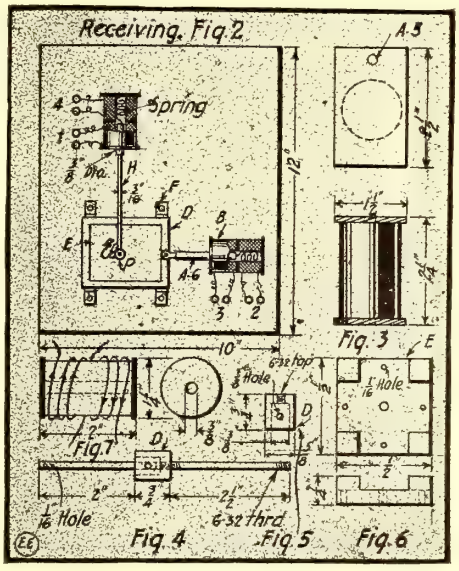
individual parts are given in the accompanying drawings. These do not require much description. Fig. 1 represents the transmitting station, which consists of four resistance coils at right angles to each other and their sliders moved by brass rods, which are joined together at a common point E, where a pencil or pen is attached. These rods are swiveled by means of universal joints D, D, D, D.



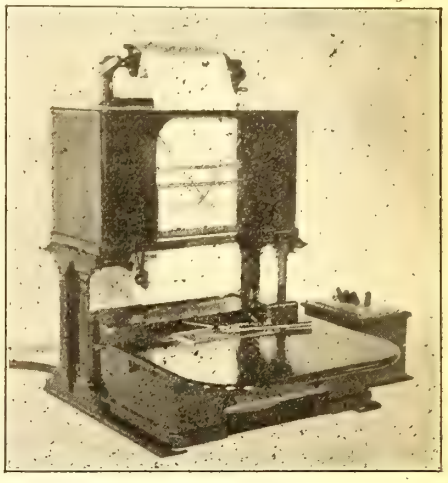
The resistance coils A, A1, A2, A3, are wound with No. 26 B. & S. German Silver wire on wooden cores as shown in Fig. 3, and well shellacked. Ordinary tuning coil sliders are then placed on top of the coils. Four of these resistance coils are made and then fastened to a wooden base 16"x16"x ¾", by means of wood screws. These coils should be placed at right angles to each other, as shown in Fig. 1. A small hole is drilled on the back end of each slider and threaded with a 6-32 thread. Now construct the slider rods, which consist of two pieces of brass rod threaded together by means of a universal joint D. The slider rods are now inserted in the end holes A5, Fig. 3, on each side of every resistance coil bobbin. The details of construction of rods are shown in Fig. 4, and of universal joints at Fig. 5. All parts are made of brass. After the coil and rods are made and assembled on the base, connect all the rods at a point E by means of a brass center block shown in Fig. 6. Four small pins are inserted in each hole through the rods so as to allow a free play between the rod and connector. Each set of terminals of the coils are connected to their respective binding post as indicated.

The receiving apparatus is similar to the transmitter but different in construction. The receiver consists of two solenoid type electro-magnets arranged as shown in Fig. 2. These solenoids have two sets of windings on them, and wound in opposite directions. The two bobbins are made of hard rubber and details of dimensions are shown in Fig. 7. After the bobbins are made according to dimensions, wind in one direction and one-half of the spool, with 200 feet of No. 24 B. & S. copper magnet wire, and then wind the other half and in the opposite direction with the same amount and size of wire. Both coils should be wound exactly the same. Now construct the movable cores, which consist of two pieces of soft iron 1¼"x⅜" in diameter. On one end of these cores a No. 10-32 thread is made and a small brass rod H with No. 10-32 thread on one end is inserted, as shown in Fig. 2. Two small springs are then placed behind each end of the cores of the solenoids as shown.

The *writing board* E, Fig. 2, consists of a thin brass plate 8"x4"x¼", placed between four brass angle pieces F, suitably grooved, so it can be moved easily by the electro-magnet arm A 6, Fig. 2. This arm A 6 is the core of the electro-magnet B and is made from soft iron 2½"x⅜". A small hole is made in one end in order to attach it to the *writing board* E.

Now place these parts on a hardwood base 12"x10"x½" and arrange them as shown. Connect the respective coils to a pair of binding posts. The apparatus is now ready for use. Connect both transmitter and receiver as follows:

Binding post 1 of sender connect to binding post 1 of receiver and binding post 2 of sender to binding post 2 of receiver, and so with 3 and 4. It is to be remembered that a battery is connected in series with each set of connections. About four cells in each circuit will work very nicely. Draw a figure on a piece of paper and then place it on the transmitter writing plate



Details of Various Parts Constituting the Home-Made Telautograph.

and trace it by means of the pencil. A piece of paper is now attached to the *receiver writing plate* and a pencil inserted on the rod hole P and laid loosely on the paper. As soon as the transmitter pencil moves the receiving pencil will follow and in this way it will reproduce the exact image. Writing may be sent over the wire just the same.

The principle which this machine depends upon is the variation of resistance which the transmitter's resistance coils create by the movement of the sliders and thereby causing a different current strength to pass through the receiver solenoids by which the iron core is directly affected by the varying changes of current.

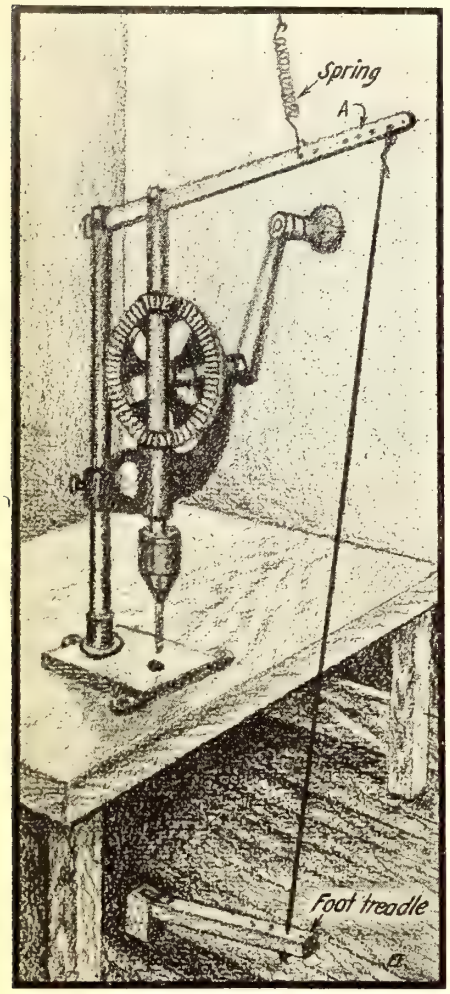
A little practise will be necessary at first

Commercial Form of "Telautograph" as Used in Banks, For Transmitting Signatures.

before good results are obtained. This machine in commercial form is now used in banks, hotels, etc. The writer will be very glad to hear from the readers of any trouble that they may have in constructing this apparatus. He will also answer any questions regarding its operation and construction if addressed in care of the Editor.

HOW TO HANDLE HARD RUBBER.

Hard rubber is one of the most frequently used materials by the electrical experimenter; first, because of its excellent insulating qualities, and second, it is easier to handle than porcelain or similar hard materials. Nevertheless a great deal is often wasted before the desired results are accomplished.



Hard rubber can be cut without chipping with a hacksaw or a fine-tooth saw. If it is cut more than half way through on one side, then starting on the other side until the cuts meet will avoid chipping. The pressure on the saw should be very light or the rubber will crack. Rubber can be drilled with ordinary twist drills in a drill press, but the stock should be laid on a perfectly flat surface and a very light pressure exerted on the drill. When finishing a base it is often desirable to have the edges rounded. This can be done with fine sand paper. To obtain a dull finish at the top it should first be sand-papered and then washed. A brighter finish can be obtained by mixing a little emery with oil and polishing the surface with it.

In working with hard rubber it is better to have it fastened to a solid support so that the drill or saw will not bend, which will cause the rubber to crack.

Contributed by OSBORN FINN.

A FOOT-CONTROLLED DRILL PRESS.

In the small hand-feed drill presses it is necessary to place the work in a vise to

Foot Treadle Control of Hand or Breast Drill.

hold same while drilling. Very often the work could be done much more quickly and conveniently if both hands were free to hold the work. The sketch shows how this may be done. The feed is simply changed from hand-feed to "foot-feed." In the small sizes it is only necessary to drill two or more holes in the handle A and attach the treadle. In the larger sizes it may be necessary to rivet a piece of strap iron to the handle so that sufficient leverage can be obtained.

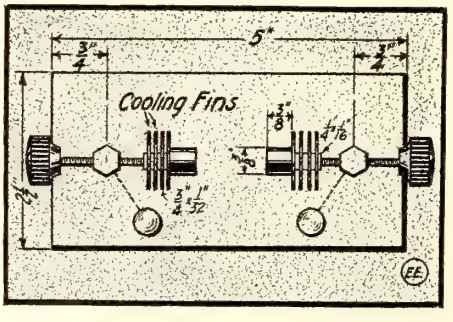
The pedal may be 2 feet or more in length, and a number of holes should be drilled in one end so that the leverage may be changed. A strong cord, chain or wire is fastened to it as shown; a hinge properly placed will allow the pedal to be thrown back under the bench out of the way when not in use.

A spring (from a window-shade roller) is good if fastened as shown to keep the drill normally above the work. Contributed by FRED'K J. SCHLINK.

WIRELESS TELEGRAPHY A DISCOVERY—NO INVENTION.

Professor Pupin, testifying in court, avers that Marconi discovered wireless by accident in the grounding of two wires. This, if so, in no wise detracts from the value of the discovery, nor does it constitute something unheard of before in the scientific world. Didn't the fall of an apple from the tree reveal to Newton the law of gravitation?

LIGHTNING'S PRANK TURNS TROLLEY POLE INTO WATERSPOUT.



Lightning struck a tubular steel pole supporting trolley wires in New York City recently, burning the wires and messengers loose and allowing them to fall into the street. A few minutes later water began to spout from the top of the pole and to ooze from the joints, making the pole a veritable fountain. Investigation showed that the lightning had ruptured a water main beneath the pavement, and that the path provided by the tubular pole was the only means of escape for the leaking water. Since to shut off the main would have deprived a large district of its water supply, the impromptu fountain was allowed to run during the night, and the main was repaired next day.

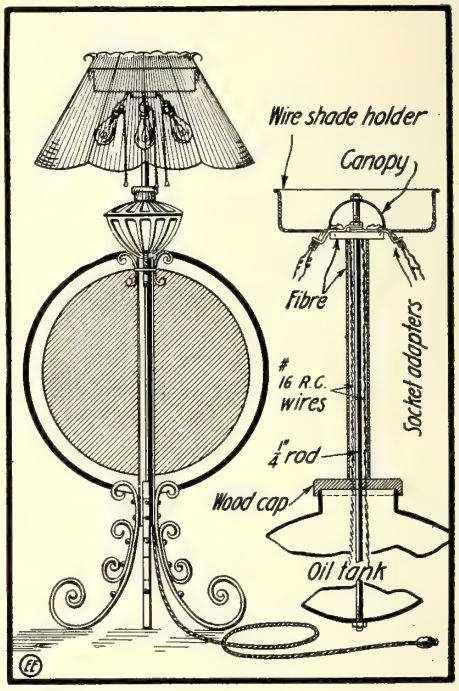
SPARK GAP WITH COOLING VANES.

An efficient spark gap with radiating fins has not only a necessary place on the wireless table but it gives the appearance as well as the qualities of a commercial station. The commercial gap with radiating fins is in many cases beyond the pocketbook of the experimenter, so something else has to be substituted.

The drawings show the general construction of the gap, but a few words of explanation may not be amiss. The base is made preferably of marble or hard rubber, but can also be made of any hard wood, and is 5x2½x¾ inches. Holes are bored and countersunk for the screws that hold the hexagonal uprights and for the binding posts, and grooves made for the connecting wires. The hexagonal brass pillars that support the gaps are 1¼ inches high. The holes through which the threaded rod passes are ¼ inch from the top and tapped with an 8-32 screw thread. Holes are also drilled and tapped in the bottom of the pillars for the screw which holds them to the base. The pillars are placed 3½ inches apart, giving a gap of 2 inches, which is more than you will probably need. Each piece of the threaded brass rod is about 2 inches long.

Regular zinc spark-gap ends are used. These are tapped to fit an 8-32 thread. The radiating fins are cut from sheet brass or copper 1/32 inch thick. These are drilled to pass the 8-32 thread, or may be tapped and screwed on, which insures a more solid and heat-efficiency construction. These are separated by ¼x⅛-inch hexagonal brass

Spark Gap Cooling Enhanced by Washers Acting as Vanes.



nuts. These are screwed up tightly against the fins and one should be put behind the last fin. Do not polish the surfaces of the fins, as this tends to reduce the radiation. They may be painted with aluminum paint if desired.

Hard-rubber binding posts and knobs add a finished and neat appearance to the instrument.

ELECTRIFYING AN OIL PIANO LAMP.

Having one of the old style, but artistic, type of oil piano lamps on hand, the writer conceived the idea recently of converting this into an electric lamp. The accompanying drawing shows how this was done, and in the writer's case it was wired for three sockets. Chain-pull sockets are best employed, and thus one or more lamps can be lighted as desired. The detailed sketch shows how the upper part of the lamp

Converting Oil Piano Lamp Into Electric Type.

was converted to support the three electric sockets. First, the three sockets were secured together on a round fiber disc ¼ inch thick by three inches in diameter with three gas-electric adapters. These adapters, which have flat brass legs on them about 3 inches long, were bent, as shown, so as to support the three sockets at an angle downward. The three tails of the socket holders were held under the brass nut at the end of the ¼-inch threaded brass rod indicated, which passes up through the oil tank and fiber tube. The fiber tube was about 1 foot long and ⅜-inch bore by 1 inch outside diameter. No. 16 rubber-covered fixture wire may be used to lead up through the stem of the lamp, a piece of flexible lamp cord of whatever color silk finish desired being secured to these No. 16 wires inside the lamp.

A wire framework to support the silk-draped shade shown was fastened also under the nut on top of the rod which clamps the fiber disc and socket holders. Undoubtedly there are many readers who have one of these lamps of the oil type lying around, and it can thus be changed into an electric type, and, with a new style shade on same, made of fabric, etc., it will make a very artistic addition to any parlor or drawing room. This particular lamp was finished up with some dull black Japalac all over. The shade was of pink china silk, artistically ruffled or draped.

DESTROY WIRELESS STATION.

British troops destroyed the important fort and wireless station at Bukeba, on Lake Victoria-Nyanza, German East Africa, on June 25, the Government bureau announced.

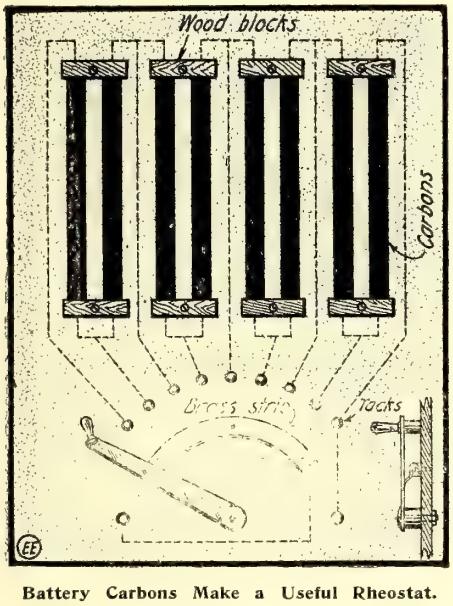
A TRIP THROUGH THE COOPER-HEWITT ELECTRIC WORKS.

(*Continued from page* 147.)

quartz tube it thereby gives a greater amount of light for its size. This lamp is used where longer lamps cannot be used. It is also of special benefit in electro-therapeutical applications.

The latest use of the mercury tube is in wireless telephony. Dr. Peter Cooper Hewitt has found out that, when specially built, they develop a high-frequency current when they are excited by an alternating current, and successful results have been obtained in this line. Dr. Hewitt expects to develop his system to such an extent that ordinary persons will be able to handle his wireless telephone apparatus just the same as the ordinary wire telephone used to-day.

NEW USES FOR ELECTRIC LIGHTS.



Anyone suffering from earache, toothache, neuralgia and possibly other ills will often obtain relief by taking an electric light—one on a pulley—to bed with them. Place the bulb on the part affected and it will very often ease the pain. This is a very handy way to get relief when stove fires are all out and the rooms cold.

My son once used an electric fan to cool a kettle of soap he was cooking to keep the soap from boiling over! It worked splendidly, too. It could be used in cooking jelly.

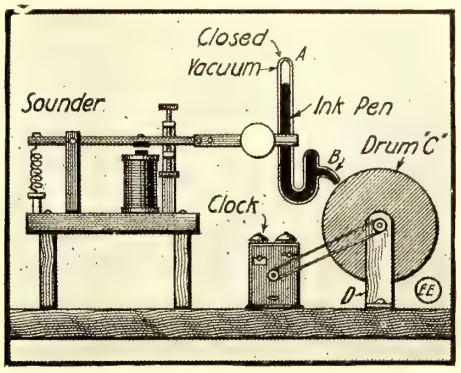
MRS. ELLIOT ROSS.

A CHEAP CARBON RHEOSTAT.

The construction of my home-made rheostat is as follows: On a board about 5 inches wide, ½ inch in thickness and 8 inches long fasten 8 brass-headed tacks for switch points, about half an inch apart. Or better yet, procure a drill and make holes through the board. Then in each one fasten

Battery Carbons Make a Useful Rheostat.



a binding post from a carbon rod of a dry battery. Now procure a circular-shaped brass strip as seen in the illustration. Get a switch handle and fasten same in position as indicated. For the resistance procure 8 sticks of carbon either from small flash-light batteries or dry cells. These carbon sticks are fastened by small blocks of wood screwed on board. String the wires under the base and make the other necessary connections with some bell wire.

ROOM ENTRANCE RECORDER.

Herewith are given directions for the construction of a novel and simple device to announce that an entrance has been made into a room.

First secure a telegraph relay or sounder, and on the armature place an inker. Below, where the hammer strikes, place a paper-covered drum, as shown. In the normal position the sounder armature containing the inker does not touch the paper. In

Room Entrance Recorder With Siphon Pen.

other words, the sounder is open. Connect one pole of the sounder to one battery pole and run a wire from the other pole of the sounder out under a carpet directly in front of the door. Then take another wire from the pole at the other end of the battery and lay it across the first wire under the carpet. Cross one of the wires over the other, but make sure that they do not touch.

When a person steps on the carpet in the act of entering the room the two crossed wires are pressed together by the weight of the foot, thus closing the circuit and actuating the sounder. The inker and hammer come in contact with the paper covering the drum, thus making a mark on same, and thus the record is made.

Different inking devices may be used, and the longer the ink supply lasts the more useful becomes the apparatus from a time-saving aspect.

As depicted in the sketch, the inker is simply a siphon-type glass tube drawn out to the shape indicated. It retains the ink by atmospheric pressure, there being a partial vacuum at the top of the sealed-up end A. Invert ink tube when filling. A "pen" point may be drawn out as at B. This principle is used on several commercial recorders. The paper-covered drum C may be a baking powder tin suitably mounted on standard D D. It may be driven by a clock motor, as shown, the drum C being arranged to rotate, say once every 12 hours, etc. Some burglar alarm matting works very well for the circuit closer.

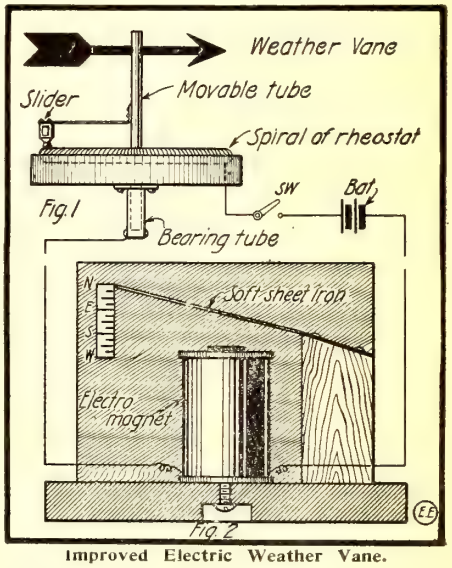
J. HOWARD MASON WIRELESS EXPERT.

Green Island, N. Y., has a prodigy in the person of J. Howard Mason, of 20 Hudson Avenue, eighteen years old, a specialist in wireless telegraphy and an electrical expert with a brilliant future. He is the son of Edward A. Mason, foreman of the passenger equipment departmen of the Delaware and Hudson shops in Colonie. A graduate last June of the Whitehall High School, young Mason intends next year to enter the Rensselaer Polytechnic Institute, a candidate for the degree of electrical engineer. The Masons moved to Green Island from Whitehall last May. From the roof of the Mason home to the roof of the nearest house on the south stretches the wireless apparatus, which has attracted considerable attention. The clocks and watches in the Mason household are regulated by government time, received by wireless from Washington every noon. The receiving end of this wireless system is in the basement of the Mason house, and the receiver itself consists of two telephone receivers which young Mason adapted. They work just as well, he says, as the regular expensive receivers. When young Mason was at Whitehall and had more time to spend on wireless telegraphy, he used to receive messages from as far as Charleston, S. C., and if the apparatus in his own house now were adjusted to its full capacity he could, but he would not, because it is against the law, send messages 100 or 150 miles. Young Mason, who this year is working for The Delaware and Hudson Company, spends his evenings in his laboratory, located in the basement, experimenting either with his wireless or with various electrical phenomena.



IMPROVED ELECTRIC WEATHER VANE.

I have seen many descriptions of electric weather vanes, but find fault with most of them. Some work with lamps, others with bells, and still others with magnets; but the common fault is the complexity of wires.

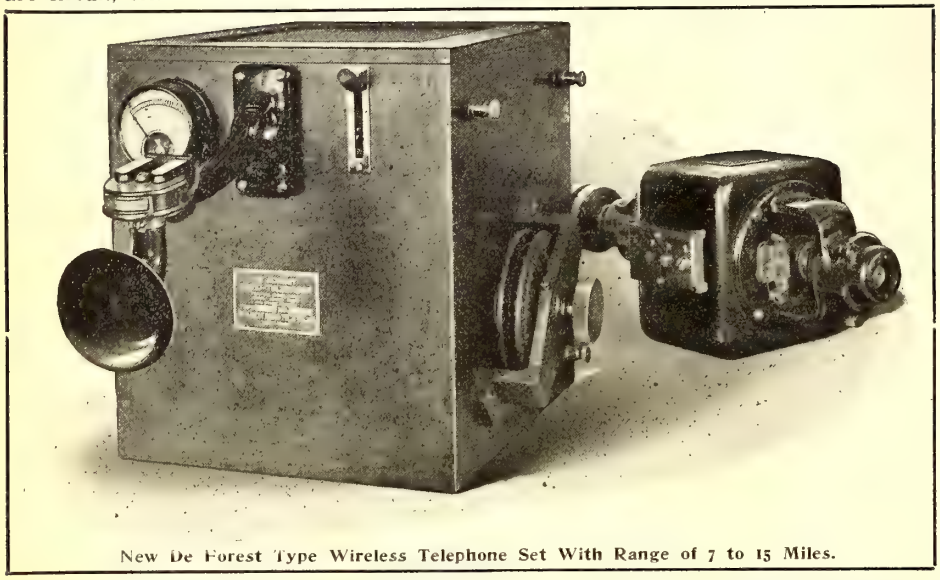
If four points of the compass are indicated, five wires are necessary; if eight points are indicated, nine wires are necessary. Besides this complexity of wires, the cost is quite heavy when wiring a four or six story building for this kind of apparatus.

It seems to me that the use of one or two wires is cheaper and simpler than that of five or nine wires.

In the type of vane illustrated here the movable axle to which the vane is fastened rotates a ball-bearing slider around the spiral of an ordinary rheostat. In the apparatus room a device similar to that shown in Fig. 2 is installed. By connecting a battery of two or three dry cells in series with the rheostat and indicator the

Improved Electric Weather Vane.

direction of the wind is acertained by the indication of the "dipping" needle on the scale.



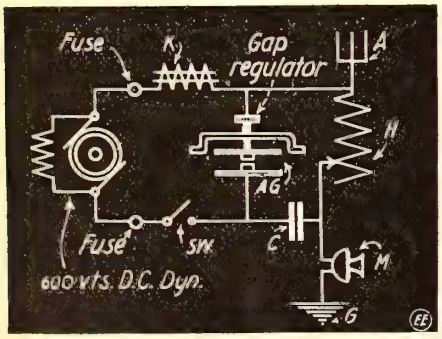
The scale calibrations must be made by experiment, as they differ in proportion to size, ohmage of magnet, current, etc. This necessitates the use of but one wire if the other is grounded. Contributed by
JENKINS SMYTHE.

WIRELESS DEPARTMENT

A New 100-Watt Wireless Telephone

One of the latest productions of the De Forest Radio Telephone & Telegraph Co. is a small-size wireless telephone outfit of improved type, which bids fair to find extended commercial application. The illustration shows the complete transmitting equipment, which comprises a special form of arc gap, together with heavy current microphone, regulating apparatus for the arc circuit, etc.

In the diagram here shown K is a large-size choke coil in the dynamo circuit, and a switch is indicated at S. The arc gap is placed at AG. An oscillatory circuit, of course as usual, composed of a condenser C, with inductance or helix H, is shunted across the arc gap AG. A heavy current microphone into which the words are spoken may be connected in the ground wire at M or in some other part of the

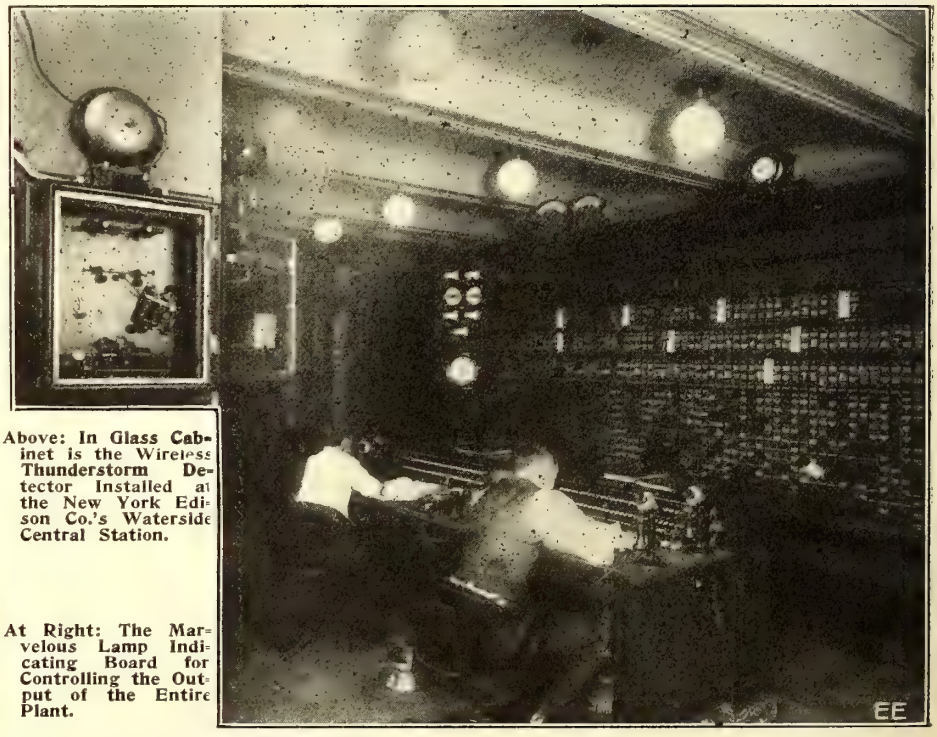


New De Forest Type Wireless Telephone Set With Range of 7 to 15 Miles.

The arc is operated from a small 600-volt D. C. dynamo, which is also shown in the illustration. This machine is driven by a gasoline engine or electric motor, whichever may be convenient.

Considerable tests have been made in the past few months of this radiophone transmitting set around New York City, and it works very well indeed. It may be said that the principal feature is the arc, and this takes place between the two platinum buttons or electrodes of small size, which are mounted on two large copper or other good heat-conducting plates. These will be observed mounted on the right-hand side of the transmitter cabinet.

A schematic diagram is given, which shows the general arrangement of these new sets, and in some of the larger sets, supplied for ship service in transmitting undamped radiotelegraphic waves, the arc is started by momentarily short-circuiting the dynamo through a large choke coil and a switch. This new set, however, is claimed to be self-starting as regards the arc, and this can be managed in several ways, such as temporarily reducing the length of the arc gap, etc.



Schematic Diagram Showing Relation of New Radiophone Apparatus.

circuit. This set will talk from seven to fifteen miles.

WIRELESS STORM DETECTOR IN CENTRAL STATION.

The most interesting apparatus at the Waterside station of the New York Edison Co. that may appeal to the experimenter is the wireless storm detector shown in the photograph. It is an ordinary radio receiving outfit of the coherer type. The use of this outfit in the station is to inform the chief operator of an approaching electric storm. Any storm that may occur a few miles away is recorded by this detector and transmitted to a sensitive relay which relay closes a secondary circuit operating a large electric bell. Whenever electric storms approach the day load is increased on account of more lamps being used. It was noted at the Waterside station that during some storms 60,000 kilowatts in five minutes' increase in load occurred.

The other part of the photograph represents the centralized control switchboard of the same powerhouse. (The switchboard of any power plant is really its brain; just as the human brain is the control center of the nerves in the body.) The various numbers on the switchboard, as seen, indicate the supply feeder numbers. Two buttons are located under each number, so that by pressing one button the operator may supply or cut off power from that particular feeder. The main switches and meters are located in a separate room. There are also two miniature electric lamps under each number, one red and one green. These lamps are used to call the operator's attention, whether to supply or disconnect any particular feeder. Thus the absolute control of thousands of horsepower is placed in the hands of one or two men.

Above: In Glass Cabinet is the Wireless Thunderstorm Detector Installed at the New York Edison Co.'s Waterside Central Station.

At Right: The Marvelous Lamp Indicating Board for Controlling the Output of the Entire Plant.

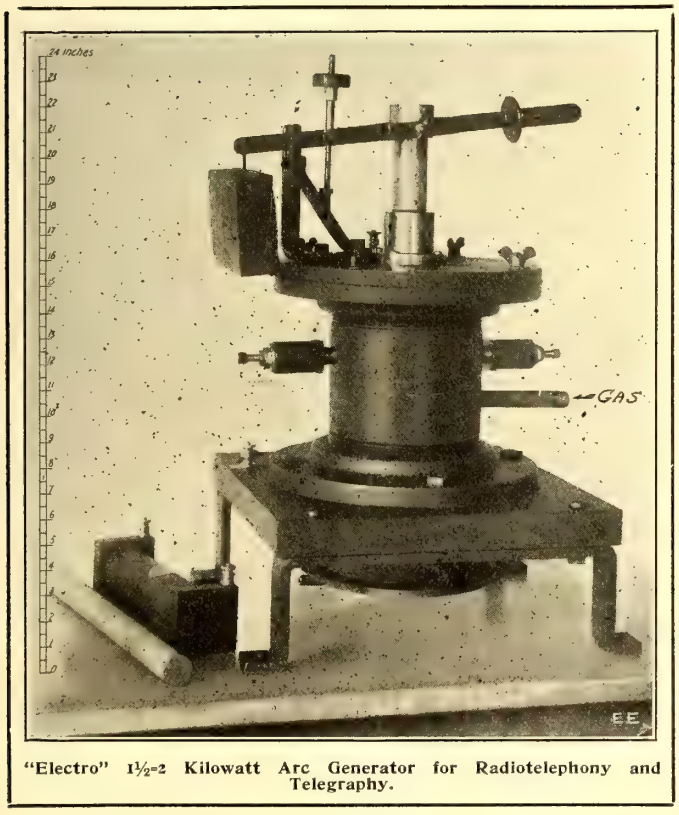
ANOTHER BOOST.

Says J. R. Rickman, of Greenville, S. C.: "I received my first copy of the *Electrical Experimenter,* and I think it is the best magazine I know of. It contains useful hints and many other interesting points, and is well worth the sum that you ask for it."

A British officer who was a prisoner on board the German raider "Kronprinz Eitel Friedrich" reports that although the Germans' wireless outfit was limited to a 900-mile radius, they sent up 8-foot kites connected by a fine wire with their wireless receiver, and in this manner picked up messages from points 2,500 miles away.

NEW 1½-2 KW. RADIOPHONE ARC GENERATOR.

A specially built and efficient type of wireless telephone arc generator of the *Electro* type is shown in the illustration. This arc measures 24 inches high over all and takes up 12 by 12 inches table space.



The arc is designed to operate on 110, 220 or 500 volts D. C. and may be used for producing high frequency oscillations for radiophonic or radiotelegraphic requirements. In the latter case, of course, a *tikker* or *tone wheel,* etc., will have to be used at the receiving station in order to pick up the undamped waves as radiated by the arc excited antenna at the transmitting station.

This particular arc has a substantial steel gas jacket on same, measuring 5 inches in diameter by 8 inches in height. This jacket is provided with gas feed pipe, as observed on the right side of the jacket cylinder, and also it carries two special low pressure quick-acting safety valves to relieve the sudden rise in pressure within the gas jacket whenever the gas in same is exploded by the action of the arc.

The upper sliding electrode with screw hand feed carries a solid carbon of large size, while the lower or positive electrode is a water-cooled copper affair of ample proportions. This positive copper electrode is placed in a powerful co-axial magnetic blast field, supplied by a substantial electro-magnet coil mounted under the base of the arc, as will be observed from the photograph.

A balance weight holds the top lever and also the upper carbon electrode carrier in an elevated position and the carbon is fed downward, as required in operating the arc, by the small feed handle shown. The crosswise lever works freely by means of a sliding boss on the threaded feed rod, so that by striking downward the outer handle on this crosswise lever with the hand the arc can be quickly started and the carbon allowed to rise again quickly. The length of the arc is adjusted by turning the feed screw as required.

Illuminating gas is used in most cases for this type of arc, and this gas has been found very efficient for the purpose after much research work by the Federal Telegraph Co. The coil shown in the picture alongside of the arc is the choke coil used in the direct current feeding circuit to prevent the high frequency oscillations generated by the arc from passing back into the dynamo circuit, etc. A suitable inductance and condenser are shunted across the arc, as usual, to form an oscillatory circuit, and this is linked with the aerial oscillating circuit either conductively, as by using a helix, or inductively, involving the use of an oscillation transformer.

"Electro" 1½-2 Kilowatt Arc Generator for Radiotelephony and Telegraphy.

Up-to-date Wireless Set of the S. S. "Olympic"

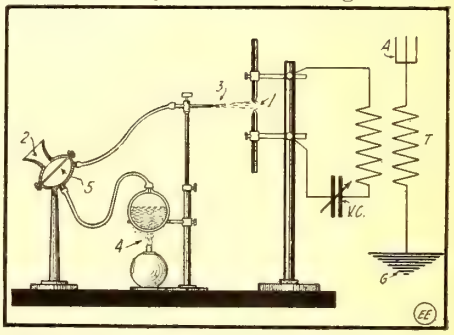
A very complete wireless set is shown in the illustration as installed on the steamship *Olympic,* one of the largest ocean greyhounds. This set, of the Marconi type, is capable of keeping the gigantic leviathan of the seas in radio communication with both shores practically all the way across the ocean. The motor generators and other heavy apparatus are installed in a separate room and control lead wires, come through the partition, as will be observed, to the manipulating resistance boxes and switchboards containing the volt and ammeters.

Also a pneumatic message tube, as well as speaking tube, communicates with the captain's cabin, and with the bridge of the vessel.

The transmitting set is rated at several kilowatts and employs a high frequency generator, which gives a musical note. Proper grounding devices are used to dissipate any static kick-back surges in the transmitting circuit, etc. These are mounted on a separate panel.

Excellent Marconi Radio Set on the Ocean Steamship "Olympic."

The receiving apparatus embodies the latest style multiple valve tuner of the Marconi type, as will be observed at the center of the instrument table before the operator, who is seen in the act of receiving a wireless message from shore when two days out. A magnetic detector is used, and this is observed mounted on the wall in front of the operator.



The usual auxiliary ship sending set is installed on the instrument table and comprises a 10-inch spark coil with suitable batteries, etc., for operating same in case of emergency or wreck.

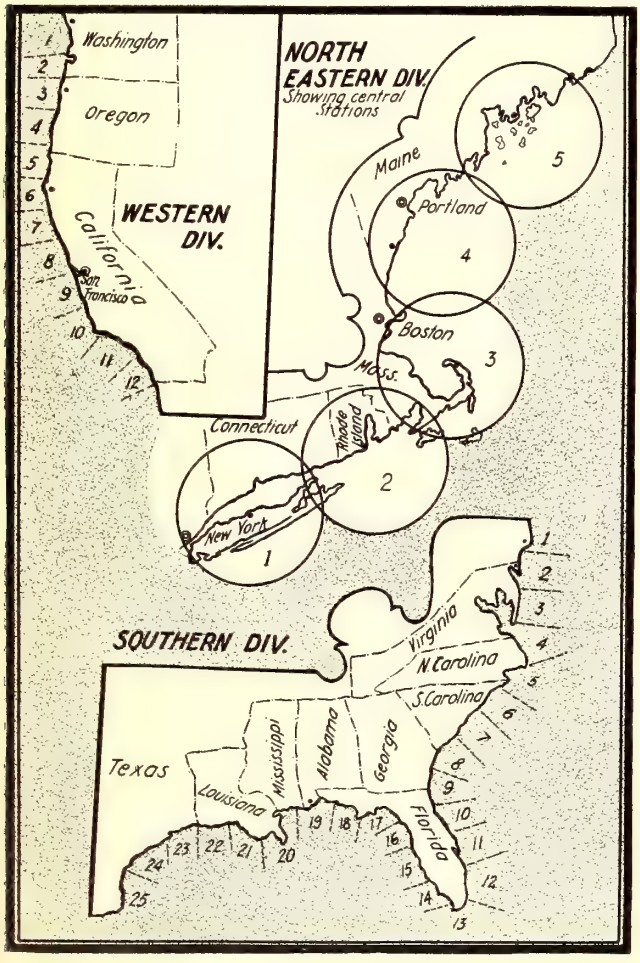
The radio station on ship board to-day is certainly a wonderful improvement over those used in the early days of the art, and conjointly, also, their efficiency and operating range is much greater in every case, enabling the ship to communicate over distances of 1,000 to 1,500 miles with ease.

A NOVEL IDEA FOR WIRELESS TELEPHONES.

There was recently issued a patent to a New York City inventor covering a rather novel method for controlling the arc current in wireless telephone transmitting stations. In substance this idea is as follows:

As will be seen in the drawings, arc "1" is used to produce high-frequency oscillations. These are transmitted to the aerial

Novel Scheme For Controlling Radiophone Arc by Varying Stream of Hydrogen Gas.



and ground "A" and "G" as usual, through the oscillation transformer "T." As is well known, it is always a considerable problem to properly impress the voice waves on the high-frequency circuit.

This inventor has very ingeniously arranged a talking mouthpiece and diaphragm "2" so that every movement of the diaphragm will cause a varying amount of hydrogen gas to be injected into the arc chamber through the nozzle "3," as will be observed in the sketch. Most wireless telephone arc generators, of course, employ a gas envelope surrounding the arc proper, and this has a decided effect on the arc. Therefore, by taking advantage of this function of the gas, this inventor has provided a very simple method which seems indeed quite practical for controlling the strength or degree of oscillations produced by the arc generator.

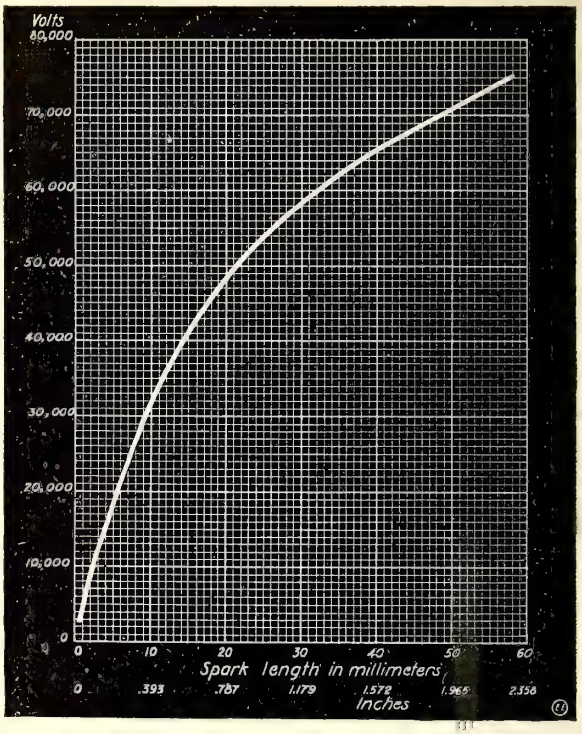
The small vessel with spirit lamp under it at "4" is the apparatus for producing the gas, which then passes through a rubber tube to the gas chamber "5," and so on through another rubber tube to the nozzle "3."

A RADIO SCHEME FOR PROTECTING U. S. COAST LINE.

A UNIQUE wireless scheme was recently brought forth by John Hays Hammond, Jr., of wireless torpedo fame, for the protection of the entire United States coast line on both the Pacific and Atlantic shores. This scheme involves the building by the United States Government of about 44 scouting aeroplanes of large size, adapted to carry powerful wireless transmitting and receiving sets. Each of these 44 scouting aeroplanes would cover a zone of its own, as shown on the appended map layout. This sketch will help to convey Mr. Hammond's idea to the reader, and it indeed seems quite feasible.

John Hays Hammond Jr.'s Radio-Aeroplane Scouting Scheme for Our Costal Defense.

Moreover, the cost is not anywhere near as excessive as that involved in building a tremendous navy of dreadnaughts and other ships, some of which cost as high as $15,000,000 apiece.



Briefly, it may be said that from the inventor's figures, covering cost of wireless apparatus for each aeroplane, aeroplane sheds or hangars, etc., the total cost of the 44 scouting aeroplanes complete, ready for service in the event of war, would be $398,500. He suggests, also, that the Chaffee system of wireless telephony would be very well adapted for the work, as it is simple in operation, very compact and light, and also requires no knowledge of the Morse telegraphic code, as does wireless telegraphy.

The Chaffee system also gives a large power in small aerials, is capable of being very sharply tuned and is remarkably cheap from a constructional standpoint.

The general operation of this scheme is to provide, of course, a small wireless station at the center of each zone point along the coast, and this would be in communication with the chief military headquarters. It is thus pointed out that the approach of any foreign naval fleets or transports would be perceived a considerable space of time ahead by the aeroplanes and that by transmitting this intelligence wirelessly to the military authorities in charge the enemy could be met by a powerful home fleet in an effort to quickly destroy the hostile vessels.

SPARK POTENTIALS.

Probably every "electrical experimenter" has often wondered how great the difference of potential might be between the secondary terminals of his induction coil or the knobs of his static machine when a spark of given length was passing. Unfortunately, no definite voltage can be ascribed to a jump-spark discharge, partly for the reason that the resistance of the air-gap between the electrodes is far from constant, for the material, size and shape of the terminals themselves play an important part, as do also changes in barometric pressure and various radiations that may traverse the space containing the spark. Inasmuch as most experimenters do not possess the requisite apparatus for measuring these potential differences directly, they must content themselves with an approximate determination based on the measurements of others. It is often stated that the potential difference is directly proportional to the length of the spark, and that it increases at the rate of 30,000 volts per centimeter of spark length. This is only approximately true for sparks of less than 2 or 3 millimeters in length, and where the knobs of the electrodes are large compared to the distances between them. As the length of the spark is increased, the increase in the potential difference is much less than that stated above, so that no idea of the voltage producing a spark of great length can be obtained from measurements made with a short one. Again, the length of spark corresponding to any given potential difference will depend upon the nature of the dielectric filling the space through which the discharge is passing.

Spark Voltages for Ball Gap. Balls Used 2 Cm. (13-16ths Inch) in Diameter.

The accompanying curve, based on data given in Dr. J. A. Fleming's "Radiotelegraphy," will be found to be a reliable and useful one for reference by the average experimenter. The ordinates or vertical distances are the spark voltages which were measured for discharges between polished metal balls 2 cm. in diameter, in air, at 760 mm. barometric pressure, and hence are only really accurate for the same conditons. However, they give the potential approximately for any discharge between metal balls in air through the range covered.

A brief study of this curve will show that for spark lengths up to 50 millimeters, or 2 inches, the potential increase with increasing length is not at all constant. As suggested above, some radiations have a marked effect on the spark length possible with a given potential difference. It is an easy matter to show that sparks will pass much more easily than normally if the gap, and in particular the negative ball, is illuminated by ultra-violet light, such as that from an electric arc light, or contained in ordinary sunlight. The same effect will result if the gap or negative ball is heated When, in any experimental work, including radiotelegraphy, small quantities of electricity are discharged across a gap, the best results will be obtained with highly polished balls of zinc or brass, and if the spark is in the open air the accompanying curve will afford a reliable means of determining the potential difference for distances up to 5 centimeters, the distances being taken between the nearest points on the two balls.

Contributed by E. H. JOHNSON.

Wireless Relays and Amplifiers

APPARATUS falling under this category are of paramount importance to all wireless workers, amateur and professional alike. We all realize that if we employ a proper relay, then with a given amount of energy much greater distances can be transmitted over, other things being equal, than if the relay is not used. Relays sufficiently sensitive for radio receiver circuits are now made and applied commercially in several different styles. The principal types now prominent or feasible are the Lieben-Reiss and DeForest gas or ionic stream valves, the Brown electromagnetic relays, the Telefunken multiple stage tuned microphone relay, and the Parsons compressed air amplifier. There are several other types on the market, but the above represent the principal basic types so far developed, excepting the Fessenden heterodyne.

The DeForest audion detector and amplifier is already familiar to most readers, and full description of his amplifier, with two and three audions in cascade, was given by this journal some time ago.

The newer gas or ionic stream relay of Lieben and Reisz, the German investigators, is similar to the audion, but possesses distinctive features of its own which render it particularly efficient as an amplifier for weak radio currents, which vary from 1 to 50 micro-amperes usually for fair signals. Their gas relay is shown diagrammatically in Fig. 1. Here a regular radio receiving circuit is represented with aerial A, ground G, coupling transformer L C, detector D of the mineral type, variable condenser V C, and a special transformer T_1. The primary of transformer T_1 takes the place of the telephone receivers usually employed. The secondary of the transformer acts on the valve tube shown at A H K.

The glass tube is exhausted of air and filled with attenuated vapor of mercury at a pressure of 0.001 mm. (20°C.), and this vapor rises from a small portion of mercury amalgam placed at the bottom of the tube. The cathode electrode at K is a platinum strip 1 mm. wide, 0.5 mm. thick and 1 meter long wound on a glass supporting stem, zigzag fashion. This strip is coated also with a thin layer of barium and calcium oxides. The anode electrode A consists of an aluminum wire spiral, while the auxiliary electrode H is made of a thin aluminum plate extending across the tube inside, between anode and cathode. It is punctured through with many holes about 3½ mm. in diameter.

Also, in general, the cathode K is brought to a bright red heat by an electric current from the potentiometer R, attached to a 30-volt battery. Across the cathode and anode is impressed 220 volts D. C. from a dynamo, etc. The voltages must be kept quite steady. A high resistance W, shunted by a condenser C, is in series with the anode, as also the primary coil of a transformer (step-up) T_2. The secondary S connects with telephone receivers P.

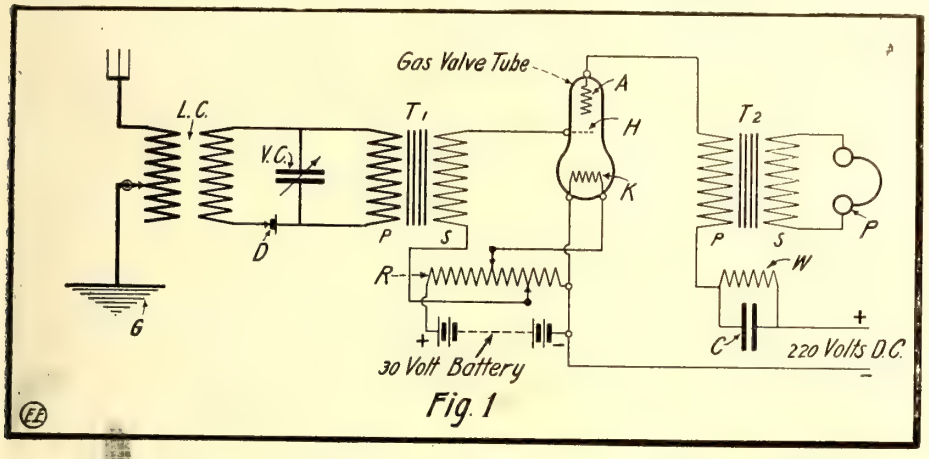


Fig. 1. Circuit and Arrangement of the "Lieben-Reisz" Gas Relay or Amplifier.

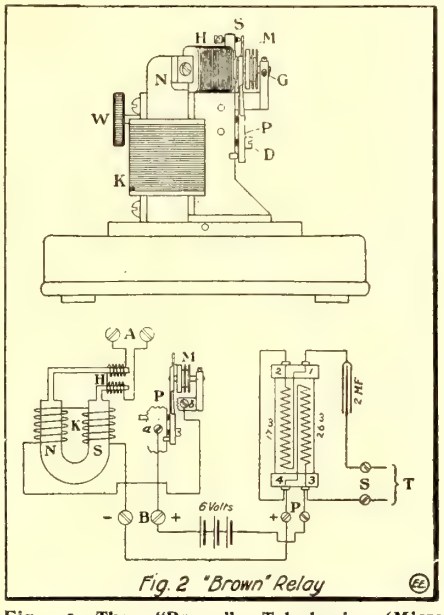

Fig. 2. The "Brown" Telephonic (Microphonic) Type of Relay Adaptable to Radio Circuits.

It was discovered by Wehnelt that heated metallic oxides emit electrons; so in the Lieben-Reisz relay the heated cathode K gives off a stream o cathode rays or electrons (cathions), which pass through the holes in the grid H connected to the radio circuit through transformer T_1. The strength of the cathion discharge through H will depend on the potential of H. Hence it will be seen that varying grid (H) potentials are constantly produced by the received hertzian wave signals acting through the circuit and transformer T_1. As the cathode stream is varied, so will the 220-volt current vary in proportion, and these variations will be heard as strong signals in phones P.

This valve tube acts therefore as a true relay, and it is said that one tube, as here shown, boosts the received currents to 33 times their original amplitude. Of course two or more tubes can be connected in circuit to give any amplification desired.

The electro-magnetic telephone and telegraph relay made by Brown, of England, is widely used for telephone current intensifying, and has been considerably employed for boosting radio signals.

Its make-up will be gleaned from Fig. 2 where N S is a permanent steel magnet frame surmounted by two magnetizing coils K, and two 4,400-ohm coils H (same size pole-pieces, etc., as used in receiver). A light spring or reed P carries a soft iron head to be attracted by the pole pieces. Attached to the moving reed is a rod joined to a delicate microphone M filled with carbon grains.

Referring to the diagram of connections in radio circuits we see that terminals A are joined in place of the regular telephones. The magnet coils K are energized by current from a battery of six volts through the primary (17 ohms) of an auto transformer P S. Across the transformer secondary (26 ohms) at 3, 1, is connected a 2 M. F. condenser in series with a pair of 120-ohm telephone receivers. Its action will be understod readily now. The varying hertzian currents react through coils H on the relay magnetic circuit balance, and cause its armature reed P and the microphone M to vary their positions. The microphone thus changes the resistance of the circuit, and these are transmitted through the transformer P S and condenser to the head telephones.

This style "G" Brown relay has an intensifying figure of about 20 times received strength of signal. Newer types can intensify 100 times and more, or several may be joined in cascade to give as high a ratio as required.

The Telefunken Co. utilizes a unique amplifier indeed, which is outlined at Fig. 3.

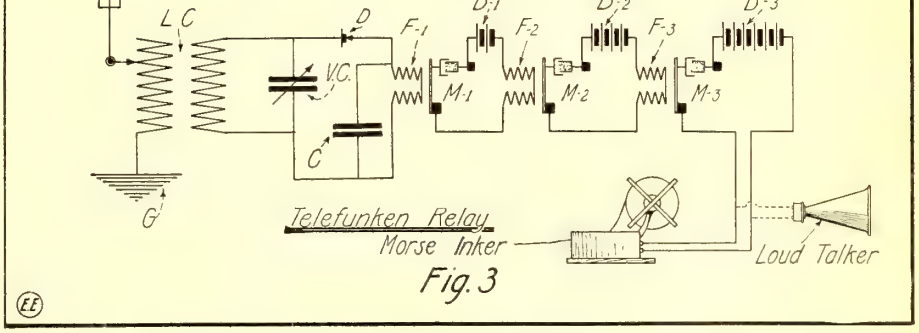

Fig. 3. The "Telefunken" Amplifier Scheme For Radio Receptors, Using Several Tuned Microphones in Cascade.

A radio coupling circuit is joined to a "tuned" reed microphone relay F_1 M_1, and

this reacts or controls the battery through a second "tuned" reed microphone M_2, etc., etc. Three microphones are commonly used. Two of these "tuned" amplifiers can receive two distinct messages on an aerial simultaneously without interference, if they and the incoming waves have a tune frequency differing by 20 per cent. or over. Such microphonic apparatus is extremely delicate and must be very carefully adjusted and supported on elastic bands, etc. The third microphone circuit can control a loud talker or Morse tape recorder as desired.

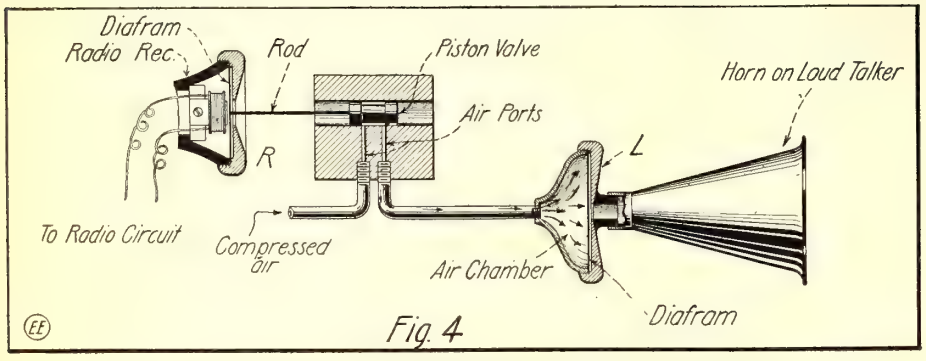

Fig. 4.—The Latest Form of Radio Amplifier Employing Compressed Air.

A new and extremely simple form of intensifier for telephone or telegraph signals is the Parsons compressed air valve, depicted at Fig. 4. A radio or telephone receiver R is connected with by a rod, as seen, to a piston or other valve. Whenever the receiver diaphragm moves or signals are received, it actuates or moves also the air valve controlling the flow of compressed air to a loud talking diaphragm chamber L, and horn as shown. This is only a rough description of this interesting device, which is now being adapted to high grade talking machines to boost the strength of the reproduced voice.

A TUNING COIL WRINKLE.

The wire on a home-made tuning coil is apt to become loose, owing to expansion and the raking effect of the slider. Here is a way to prevent it. First cover your cardboard or wooden core with adhesive electric tape, winding it on spirally and not allowing the edges to overlap. Wind your wire over this tape and it sinks in slightly, forming a groove or screw-thread for itself, so that even when the tape becomes hard, as it will do in time, the wire will not become loose.

Contributed by T. REED.

GOVERNMENT OPENS NEW DARIEN RADIO STATION.

The powerful radio-telegraphic station situated at Darien, in the Panama Canal Zone, has been recently opened for regular service by the U. S. Government.

This station is equipped with a large size Poulsen arc generator and is rated with a transmitting and receiving radius of 4,000 miles.

On the opening test radio-communication was effected between Arlington and Darien, which is a distance of 2,000 miles. There was much criticism at the time the equipment for this station was selected by the Government radio experts, because of the arc transmitter which was favored.

However, as Capt. Bullard has pointed out, the Poulsen arc has certainly proven its wonderful efficiency under the long distance conditions, especially in view of the fact that it has been in daily use for a considerable period at the Tuckerton, N. J., radio station for transmitting day and night wireless messages over a distance of 4,000 miles to Germany.

CONTROLLING 2 K.W. WITH COMMON MICROPHONE.

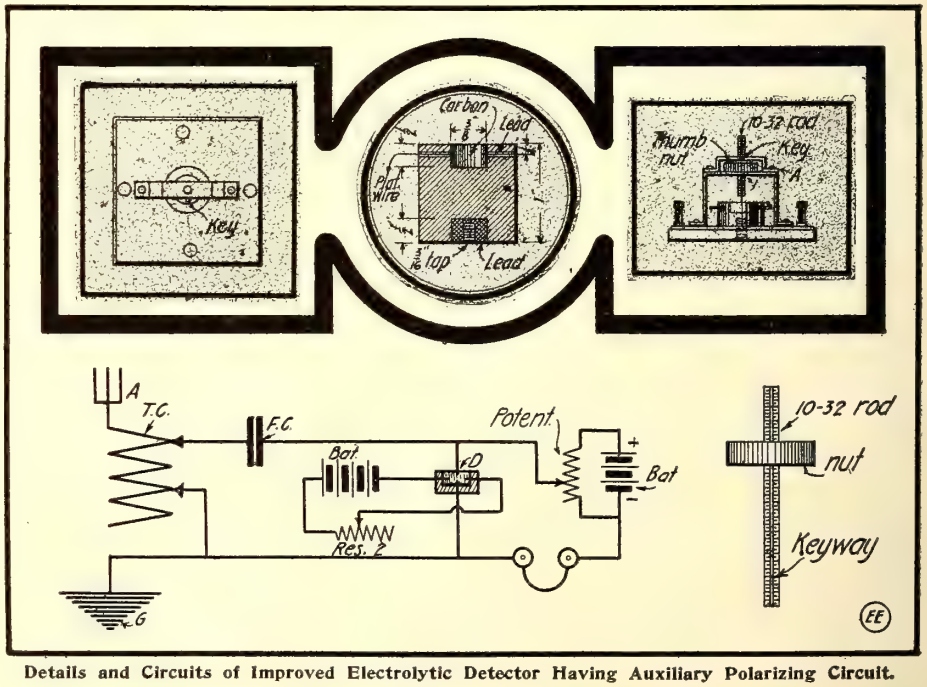
At one of the Spring meetings of the Institute of Radio Engineers, Dr. Irving Langmuir gave a remarkable paper on the "Electron Discharge in High Vacuum Tubes."

These wonderful tubes, having principally tungsten or molybdenum elements as electrodes, were described in the form of high-voltage rectifiers, high-frequency oscillation generators and radio detectors. Different entirely from the gaseous Audion, they have enormously high vacuums (as low as two 10-millionths of an atmosphere), and the electrodes of tungsten are specially treated so as not to give out when heated, any occluded gases whatever, i. e., gases held in the metals by absorption ordinarily. Hence these tubes always give similar results and are under perfect control, the same as the new Coolidge X-ray tube, as they are absolutely (practically) gas free.

Dr. Langmuir described two radio-telephone transmitters of this type used at the General Electric Works, the smaller set with pliatron tube developing 1½ amperes in the antenna and transmitting speech wirelessly from Schenectady to Pittsfield, Mass. Wonderful amplifying powers were also obtained in radio receiving, eclipsing the performance of Audions. He stated that a common microphone easily controlled 2 K. W. through one of these tubes, giving perfect control for radio-telephony. Several tubes can be joined on multiple to give more power when required.

AN IMPROVED ELECTROLYTIC DETECTOR.

The following detector will almost double the strength of the signals received. To construct it plane up a board 4 inches square for the base. From a piece of round, hard carbon cut a piece 1 inch long. Bore a hole ⅜ inch in diameter ½ inch deep on the top side. On the bottom end bore a hole ⅜ inch in diameter and ¼ inch deep. Pour the latter hole full of molten lead. Drill and tap a hole to fit a 3/16-inch machine screw in the lead. One-quarter inch from the top bore two 3/16-inch holes opposite each other. Put a platinum wire in each so that it will project a slight distance in the cup. Fasten them temporarily in place by filling the cup with clay. In the 3/16-inch holes pour molten lead, thus sealing the platinum in the walls. Remove the clay.

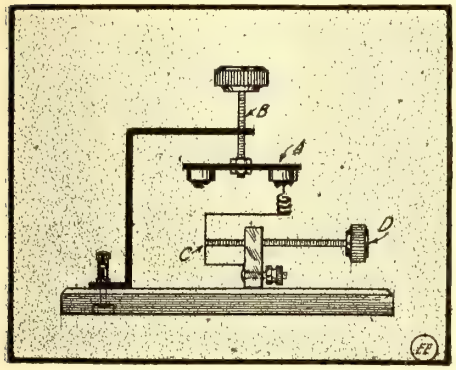


For the standard to support the thumb screw obtain a piece of brass ¾ inch wide by ⅛ inch thick and form it as shown in sketch. Drill a hole to pass No. 10-32 thread at the place marked 1 and on top of the standard solder a piece of brass as indicated at A. Drill hole in line with the other hole and of the same dimensions.

Thread a brass rod with No. 10-32 thread and about 2 inches long. Procure a nut to fit the thread. With a 3-cornered file make a small groove in the rod. On top of the standard solder a pin or key projecting slightly into the hole. This should be adjusted so the rod will slide up and down, but so it cannot turn. Solder a piece of Wollaston wire to the rod at the lower end.

To assemble fasten the cup to the center of the base. Fasten the standard in place. Slip the head in the slot, first having forced the nut in the head. Then screw in the rod. Adjust the rod the same as in an ordinary electrolytic detector. The action is as follows: When the platinum is connected with batteries it causes electrolysis, thereby augmenting the breaking of the film of gas surrounding the bare point. Resistance 2 should be high, or variable, from 50 to 150 ohms, etc.

Note that the two platinum wires entering the carbon cup must, of course, be well insulated from the carbon.



Contributed by ISAIAH ROSIN.

Details and Circuits of Improved Electrolytic Detector Having Auxiliary Polarizing Circuit.

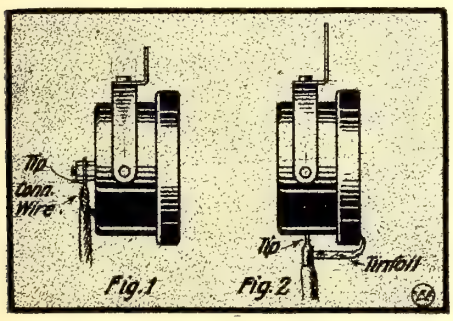
RADICAL DUST-PROOF DESIGN FOR DETECTOR.

As is well known, radio detectors of the mineral type rapidly lose their sensitiveness when the minerals become covered with dust. A great many, of course, endeavor

Radical "Dust-proof" Detector.

to overcome this trouble by covering the detector with a glass bell or by other means.

A new scheme is shown herewith which should prove efficient, and as per sketch the mineral cups are placed on a brass bar or disc A supported by an adjustable threaded rod B. A "cat-whisker" wire contact point of the usual type may be placed on a brass spring C, which has its tension adjustable by means of a threaded rod and knob D.



At first this may seem quite impracticable, but on second thought you will see that this is just as easy to adjust as if the mineral cups were facing upward, as in most detectors. This is because you cannot (naturally) "see" the sensitive spot on the mineral, and it must be found, of course, by placing the "cat-whisker" contact point on the various parts of same until the most sensitive spot is ascertained, as manifested by the loudest buzzer-test signal *heard* in the telephone receivers.

Contributed by CARL HENLEIN.

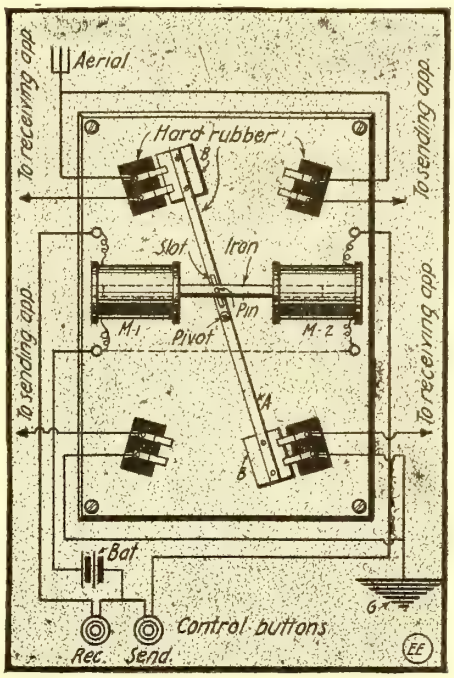
ANTI-HUM STUNT FOR RADIO RECEIVERS.

A great many amateurs are troubled by humming in the wireless receivers due to induction from neighboring electric light wires. The following directions will, if carried out, nearly always eliminate the said hum:

The first method, applying to receivers with metal shells and headbands (not covered with rubber or other insulating compound), consists of merely connecting the tip with copper wire to the shell of the re-

Anti-Hum Prevention in Wireless 'Phones.

ceiver or headband as shown in Fig. 1.



In instances where the receivers and headbands are covered with rubber or other insulating compound it is necessary to wrap a strip of tinfoil around the tip and then paste it down. Then bring it across and paste it there in such a way that it will touch the ear when the receivers are on the head. This will allow the induced current to pass through the body (see Fig. 2).

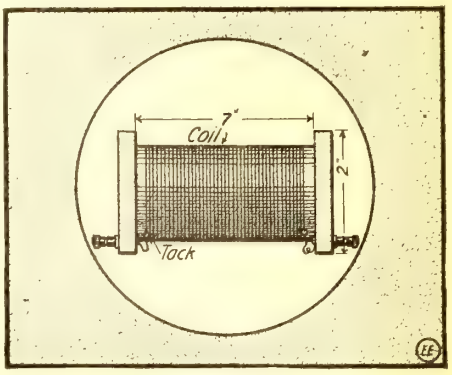
Contributed by URBAN McMILLER.

A MAGNETIC CONTROL AERIAL SWITCH.

As most wireless experimenters do not care to have the old style aerial switch on their table, etc., with which to control the aerial and ground connections from transmitting to receiving apparatus, etc., the idea here incorporated will undoubtedly appeal to them. On a wax-impregnated hardwood panel about 1 foot square, or better, a piece of marble, is mounted by means of a central pivot a fiber or hard rubber arm A. This arm may be about ¼ by ½-inch stock and 7 to 8 inches long. It carries at either end a contact plate BB of about 1/16-inch copper or brass, having their edges tapered down so that they will readily slip under the sets of contact springs C C C, etc.

These contact springs may be made of phosphor bronze or brass and of about 1/32 by ½-inch stock, mounting the springs CC about 1½ inches apart on hard rubber blocks as indicated in drawings. The connections to this switch will be readily understood by looking closely at the diagram. The pivoted arm is moved from right to

Magnetically Operated Aerial Switch.



left by means of an iron armature. This armature carries a pin which moves in a slot in the fiber arm A. Two solenoid type electro-magnets M1 and M2 serve to pull the iron armature to the right or left, accordingly as the "control" push buttons are depressed.

The electro-magnets M1 and M2 should consist of brass tubes about ⅜ inside diameter and 3 inches long. They may be wound with about 14 to 16 layers of No. 20 insulated magnet wire. A battery as shown supplies current for this magnetic control circuit arrangement. If properly constructed and by using 6 to 8 dry cells for the battery, etc., this switch will prove a very efficient and attractive addition to any radio station, and it may be placed in a small box with glass front on it; or it may be placed under the operating table, as the builder and user may elect. Contributed by

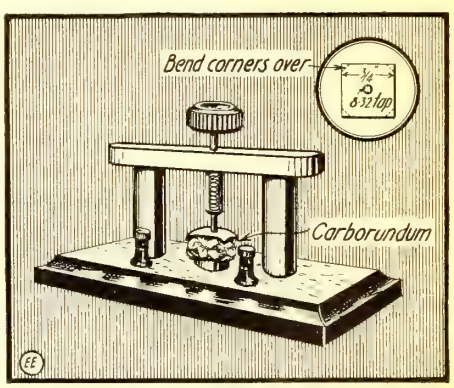
J. MILTON CRANDALL.

BUZZER-TEST RESONATOR.

I have been using an arrangement called a resonator in my wireless-receiving buzzer circuit. It is such a great help that I thought I would send you the description to publish in *The Electrical Experimenter.*

Buzzer Test Amplifying Inductance.

It is very simple. First, get a 7-inch piece of wood, well seasoned and about 1½ inches in diameter. Shellac or varnish this well. Now wind No. 26 enameled wire on this core for about 6 inches. Fasten the ends of the wires by driving in a tack or short nail at each end, and wind the wire around it a few times. The coil can then be mounted on two square pieces of varnished hardwood, which will increase the looks of the apparatus. The coil is connected in series with the regular buzzer-test wire, which leads to the detector. I find that it makes adjustment 50 per cent. easier, especially with the Crystaloi detector. Contributed by



DONALD B. ROCKWELL.

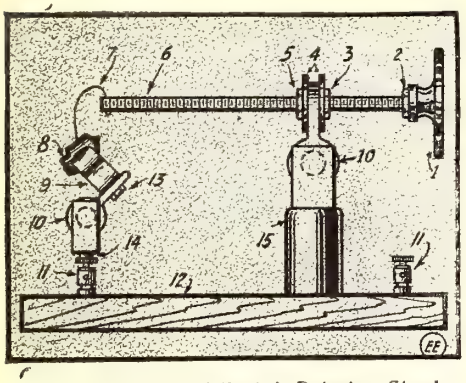
A CHEAP BUT EFFICIENT CARBORUNDUM DETECTOR.

It will be necessary to purchase one Adjustable Zinc spark gap to make this detector.

Remove the two zinc points and substitute two pieces brass, ¾" square and 1/16" thick, bending over the four corners as per diagram on both pieces. Put a hole in the center of each, and thread for an 8/32 screw. Screw the pieces on the small threaded ends left after removing the zinc points and file off the ends that protrude thru the brass squares. Purchase a piece of carborundum and place it between the brass points, then tighten down the hard rubber knob.

The detector is now ready for use. One

Carborundum Detector Made from Spark Gap.



of the characteristics is that when you tighten the thumb screw, the brass points do not move out of alignment.

Submitted by H. J. ANDREWS.

CLEVER MINERAL DETECTOR.

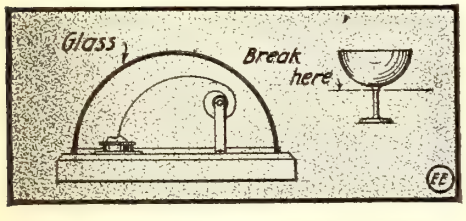
The materials needed for the construction of this detector are as follows:

Wooden or hard-hubber base 5 inches long, 2½ inches wide and ⅜ inch thick

Ball and Socket Adjusted Detector Stand.

(No. 12, referring to diagram); spark-plug ball and socket connector with hard-rubber base (10 and 15); spark-plug ball and socket connector with short brass base (10 and 14); threaded brass rod ⅛ inch in diameter by 3 inches long (6); telegraph key knob (1); clip off small fuse block (9); four binding posts (11, 11); two small washers (4); three small nuts to fit threaded rod (2, 3 and 5); small bolt and nut (13); also two thin bolts to hold uprights to base (not shown in drawing). The four binding posts are mounted, two in front and two in the back, the wire connections being made from the back one on the right-hand side in the drawing to the front one; then to the bolt which holds upright in place, making contact with brass part of ball and socket joint, the same being done on the other side. Connect the 'phones to the front binding posts. Aerial and ground to the other two.

The "cat whisker" is made fast by passing one end of it through a small hole which is drilled in the brass rod, making the wire fast by soldering it in place. By unscrewing the two nuts (3 and 5) you may move the rod to any desired position.



The spark-plug ball and socket connectors are made by the Connecticut Co., and may be obtained in any auto-supply store. Contributed by

WILLIAM DAVIS HAWK.

DUSTLESS DETECTORS.

Dust gathering on detector crystals necessitates repeated washings if best results are desired, and a good plan for keeping the dust out, still allowing observation, is shown in the sketch.

A wine glass, preferably of thin stock, has its stem broken off as near the bowl

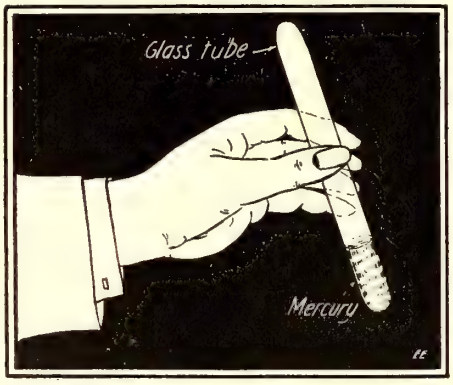
Glass Goblet Serves to Protect Detectors from Dust.

as is safe and the rest of the stem is carefully ground off on an emery wheel or grindstone until the bowl has a smooth appearance. It may then be smoothed up on an oil stone. The dimensions of the detector itself must conform with the inside of the glass, and for that reason no dimensions are here given. Contributed by

FRED'K J. SCHLINK.

MAKING TUBES FOR TUNING COILS.

Here is an easy way to construct a very serviceable tube. The tube's great advantage is its lightness.



Take a strip of cardboard several feet long and a foot wide. The width may, of course, be varied if a longer or shorter core is desired. Put the piece of cardboard to soak in water till it is very soft and limp.

Next take a rolling pin or some other cylindrical object and wind the wet cardboard on the cylinder, glueing or shellacking one layer of cardboard to another. When you have wound on enough cardboard to give you the thickness you want, bind the cardboard with heavy string and put the bundle into a warm oven. In a few hours take the pin out, and the cardboard when taken off will be so stiff that you may easily wind it with wire of almost any size. NORMAN HALL.

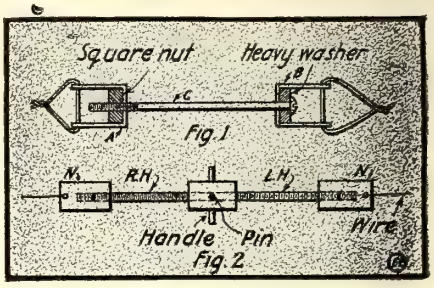
A SELF-EXCITING GEISSLER TUBE.

When the mercury in a barometer tube is agitated the friction of the mercury on the glass generates electricity and produces effects which are visible in the dark.

The self-exciting vacuum tube herewith shown operates in the same manner. The electrical effect is produced by the friction

Geissler Tube Using Mercury Only, and No Current.

of mercury on the inner surface of the glass vacuum tube as the tube is inverted or shaken. The full effect is realized only when the mercury is allowed to flow quickly from one end of the tube to the other, but any agitation of mercury in the tube produces some phosphorescent light. This principle is utilized as an auxiliary signal in bell buoys and whistling buoys.



GERMANS' TREBLE WIRELESS PLANT.

The big Telefunken wireless station at Sayville, L. I., the plant through which the German Government transmits most of its official communications to the United States, and through which the German Embassy communicates with Berlin, has been quietly, almost over night, so to speak, increased from a 35 K. W. plant into one of 100 K. W. Three 500-foot towers have been added to the aerial system.

The transformation of the Sayville plant into one of the most powerful of the transatlantic communicating stations in this part of the world has been carried on so quietly that very few persons outside of the radio officials of the Department of Commerce and a few naval officials connected with the wireless naval service have known what was being done. The new and larger equipment was shipped from Germany via Rotterdam.

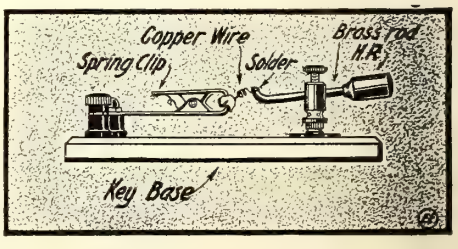
A CHEAP TURNBUCKLE.

The accompanying diagram (Fig. 1) shows a turnbuckle which can be readily made by everyone. The pieces A and B are of strip brass or iron about ⅛ inch thick and about ½ inch wide. At C is an iron bolt about 3 inches long with a round

Simple Form of Turnbuckle.

head. The turnbuckle is readily tightened with a screwdriver.

At sketch (Fig. 2) is depicted another easily made and serviceable type of strain turnbuckle. It is made of preferably nothing smaller than a No. 14-20 threaded steel rod, one-half the rod being threaded left-handed and the other half right-handed. The steel nuts N N are threaded right-handed and left-handed accordingly, and when the center handle, which is pinned to the threaded rod, is revolved by hand it causes the nuts N ... to recede or approach each other.



AN ALLOY FOR RADIO CRYSTALS.

Dissolve as much tinfoil (not lead foil) as possible in 5 cents worth of mercury or quicksilver. Work this mass with the fingers until no more tinfoil can be used. Place the mass in a small cup and hold the cup over an alcohol flame with a pair of pliers until the mixture melts. Pour it onto a paper and let it cool. It may then be broken into pieces and kept indefinitely. This alloy melts easily and the crystals can be mounted in it. It is quite hard when cold.—Contributed by

LLOYD STRATTON.

A SIMPLE GALENA DETECTOR.

The following is a description of a galena detector which I have made and found to be very sensitive. The base was from a telegraph strap key. The key lever was taken off and a helix clip cut off and drilled and put in its place. The contact screw was then removed and a binding post put in its place, under which was placed a battery burr, which served to

Effective Galena Detector.

raise the binding post, and also acted as a lock nut so that the binding post could turn. A small brass rod was placed through the binding post and on one end was mounted a suitable hard rubber handle and to the other end was soldered a coiled piece of copper wire, also the rod was bent as shown in the drawing.

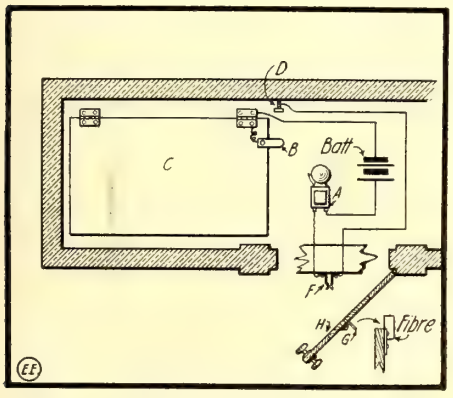
HOW-TO-MAKE-IT DEPARTMENT

This department will award the following monthly prices: FIRST PRIZE $3.00; SECOND PRIZE $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

FIRST PRIZE $3.00.

FOOT-OPERATED PUSH-BUTTON FOR TEST BUZZER.

It is often found inconvenient when adjusting a crystal detector such as that of the galena type to push with one hand the button or switch controlling the buzzer circuit. In order to allow the freedom of



Useful Foot Switch for Buzzer Test, etc.

both hands for adjusting the apparatus yet enable one to operate the buzzer when desired, a switch arrangement that may be operated by the pressure of the foot is illustrated in the accompanying drawing. This device consists of a wooden block A, measuring 2 by 1⅛ by 2 inches; another block B, measuring 2½ by ¼ by 2 inches, which is used for the base; a metal pin C, which is threaded at one end and fitted with the composition knob E; a spring on the pin C shown at K; a metal strip F and the binding posts G. The construction of the push-button can readily be followed by studying the drawing.

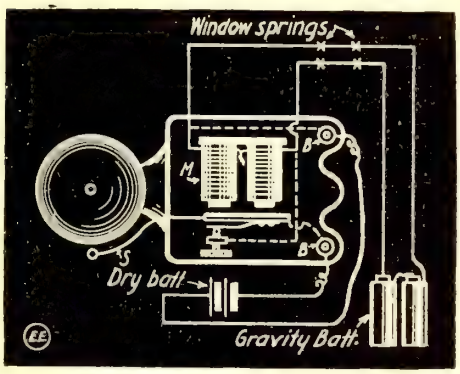
THEODORE GATHMANN.

OPEN DOOR BELL ALARM.

Below is a sketch of a device which I think a number of the readers of the *Electrical Experimenter* would be interested in. In my house one of our cellar doors is in the pantry, as illustrated. By carelessness or forgetfulness the cellar door was left open three times, each time a person falling into the cellar. This is what brought about my idea of this little device of *safety first*.

Alarm Bell Rings If Cellar Door Is Open When Pantry Door Is Opened.



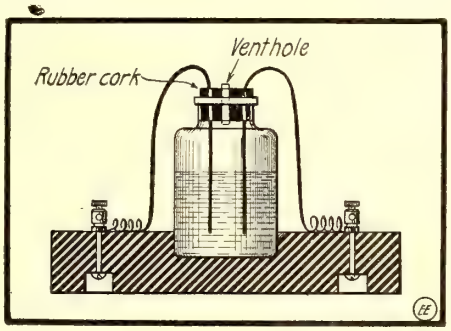
Here is how it works: When the cellar door C is left open spring B comes in contact with the nail D, thus connecting that end of the line. When the pantry door H is opened, the knife G passes between the contact spring points at F, thus completing the circuit and ringing the bell A. This gives ample warning of the danger.

Contributed by A READER.

SECOND PRIZE $2.00.

CLOSED CIRCUIT BURGLAR ALARM.

Given two dry cells, two gravity cells, some wire and the necessary tools; connect the two wires from the gravity battery to the magnets (marked "M" in the drawing). Connect the wire from the dry battery to the regular binding post of the bell. When the gravity cell circuit is broken it allows the striker "S" to rebound and touch the contact screw of the bell, which starts it vibrating in the usual manner. I have found this very efficient and at the same time the cheapest and simplest closed circuit burglar alarm on the market.



Simple Closed Circuit Burglar Alarm.

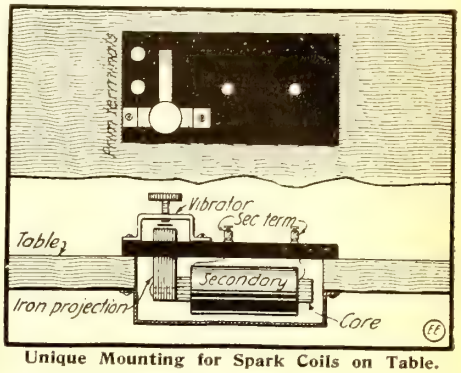
Contributed by L. A. MADISON.

A HANDY POLARITY INDICATOR.

Mount a bottle in a block of wood as the cut shows. Arrange two copper wires to dip in the solution of salt water or water to which a slight amount of sulphuric acid has been added. Mount two binding posts on the wood block. When current is connected to the binding posts

Handy Polarity Indicator.

the negative wire will indicate itself by the greater formation of gas bubbles around it. Contributed by
CHARLES ROSENTHAL.



INSTRUMENT LACQUER.

A very good lacquer can be made by dissolving some alum in banana oil. With a small brush paint over the instrument with laquer and let it dry thoroughly before handling.

THIRD PRIZE $1.00.

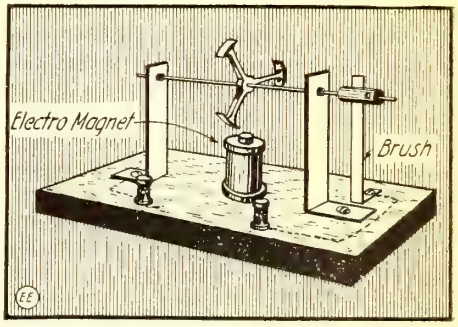
A NEAT ARRANGEMENT FOR SPARK COILS.

The articles required for this piece of apparatus are a spark coil (any size), with vibrator and binding posts, and a piece of hard rubber about 1 inch longer than the

Unique Mounting for Spark Coils on Table.

core of the coil and 3 or 4 inches wide and ¼ inch thick.

The coil is taken from its case, together with the vibrator and binding posts, and to one end of the core is fastened by means of a nail a piece of laminated sheet iron core, so as to project at right angles; it is cut off at the proper length to work the vibrator, as shown in sketch.



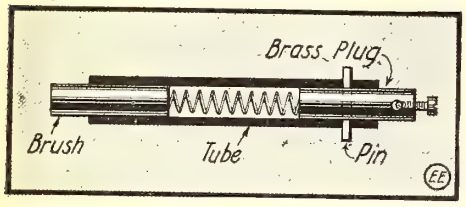
The rest may be best understood from the drawing. The coil itself is put under the table, in oil if desired, and the hard rubber is mounted on the top of the table.

This gives a finished appearance to the instrument very desirable in well arranged radio plants.

Contributed by W. F. ALLSTON.

UNIQUE BATTERY MOTOR.

A short while ago I made a little motor as shown in the illustration. The armature was a three-pole one from an old motor and had the windings taken off. I mounted the axle on which the armature and commutator were fixed between two metal uprights, and under the armature put an electro-magnet from an old bell. The brush was adjusted so that the little screw on the commutator just hit it. To



Simple Electric Motor Having But One Electro-magnet.

make the other connection to the commutator I put some small pieces of wire in the screw holes so that they pressed against the shaft.

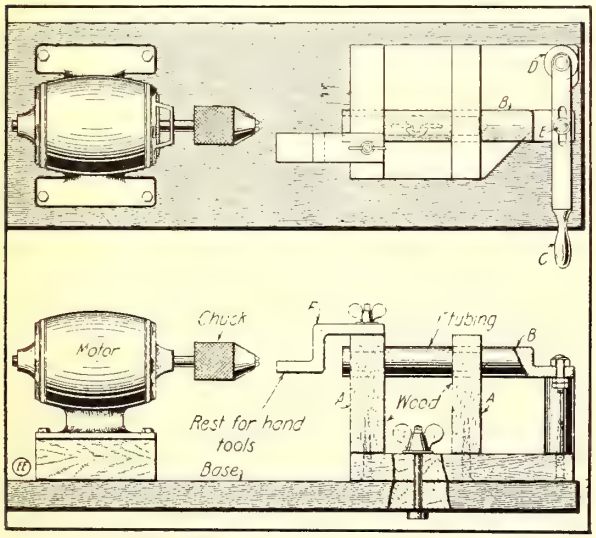
The current coming from the battery passes through the electro-magnet, upright, axle, commutator, the brush and then back to the battery. JOHN B. MOORE.

BRUSH HOLDERS FOR SMALL MOTORS.

The illustration below shows how very efficient brush holders for small electric motors are made. To begin with, a small piece of fiber or hard rubber tubing is procured and a round carbon brush slides inside the tube; pressure being exerted behind the brush by a spiral spring, as perceived.

Easily Made Brush Holders for Small Motors.

Contact is made from the brush through the spring on to a brass terminal connecting plug, as indicated.



When the brush holder tube is clamped in the machine against the commutator there should be about ⅛ inch or less space between the end of the insulated tube or *brush holder* and the commutator.

To remove the brushes for renewals, etc., when the machine is assembled and when it is not desirable to remove the whole brush holder for the purpose, the brass terminal plug is easily removed by taking out the brass pin shown. The spring pressure exerted between the terminal plug and the brush will always hold the pin in place, but in some cases a small cotter pin is utilized, so that it will not work out, due to vibration.

HANDY ATTACHMENT FOR DRILLING WITH ELECTRIC MOTOR.

Those having a small electric motor at hand can very easily rig up a handy drilling or boring attachment, as shown in the illustration herewith.

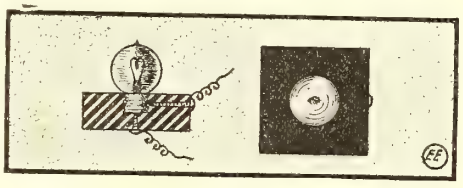
The motor is simply mounted on a hard wood or iron base and the shaft is threaded to hold a small drill chuck, which can be purchased at any machine or supply house at small cost.

Drilling, Boring and Turning Attachment for Small Motors.

At the other end of the base is arranged a hard wood or iron frame having two uprights on it at AA. These are drilled so as to pass around a sliding bar B. This bar is moved back and forth by handle C pivoted at D, and by a slot at E in which a pin fastened on the sliding bar B travels, as it is moved back and forth.

To those desiring to use hand turning tools, etc., a simple brass or iron support F will prove useful. This is held by a heavy machine screw wing-nut, as perceived, so that it may be swung out of the way when not in use. The sliding bar B is used to press the work against the drill, similar to drilling in a lathe, and in fact a very good lathe for light work can be made in this way by placing a conical *center* in the spindle B and gripping the work in the chuck, or a second center may be formed on the end of the motor shaft and the work held by a "dog" clamp arrangement. A speed controller is best used in series with the motor, thus giving a wide range of usefulness to this idea.

Contributed by E. L. H.



STATIC MACHINE PLATES.

Many experimenters who wish to build a Wimshurst static machine find it difficult to obtain the necessary plates. Phonograph plates are very suitable for this purpose. Use records that have a song on one side. The tinfoil sectors can be mounted on the smooth side of the record plate with thin shellac, glue or beeswax.

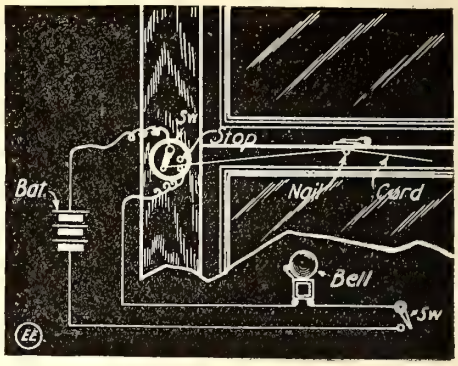
MAKING SMALL LAMP SOCKETS.

The sketch presented is a socket for a miniature candelabra, or single point Edi-

Lamp Socket Made from Fiber, etc., and 2 Screws.



swan base lamp. It is very simple. The drawing, I think, will explain it all.

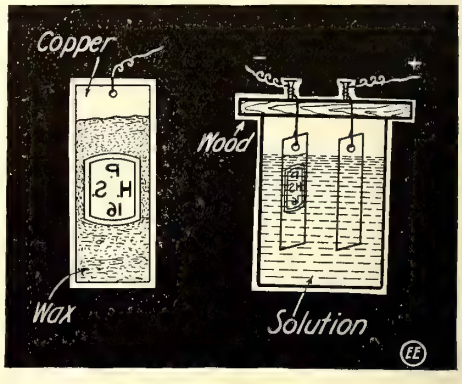
Contributed by ROBERT McCREADY.

Arc Lamp: An antediluvian lamp which archæologists agree was invented by Noah and used on his hydroplane "The Ark" (from which it takes its name) before the new lighting regulations were enforced.

A NOVEL WINDOW BURGLAR ALARM.

Articles: Two switches (as shown), three cells of battery, some wire, a common hook. It does not require a long description, as the sketch clearly explains itself. Fasten switch on one side of window, as shown. Screw in your hook right under the sash lock of your window. Fasten bell and switch for same at some convenient place in another room. The idea of this arrangement is as follows: Suppose you set the alarm. You fasten a fine silk thread, or cotton string, from the handle of the switch, string it through the hook you have screwed right under the lock of window and tighten it on another small tack on the right hand side of the window. The intruder comes along, gently lifts the window, the gentle raising slowly moves the handle of the switch to the right (see sketch) to the switch point. A little tack in the switch prevents the handle of the switch from moving further. The burglar keeps on lifting. The thin silk string is broken by the pressure and the circuit between the alarm bell in your room is closed until you throw back your switch.

Burglar Alarm Using String to Close Switch.



It is a very simple and reliable burglar alarm. If properly adjusted no sneak or burglar can enter your dwelling.

Contributed by JAMES PEABODY.

MAKING SMALL ELECTROTYPES.

This small electrotype is a model of the way all the cuts for printing books are made. First procure at a drug store two ounces of blue vitriol and an ounce of graphite. Also procure two copper strips 6 inches by 1½ inch, preferably with wires soldered to them, and some beeswax or paraffin.

A pint fruit jar should be filled about two-thirds full of water and the two ounces of blue vitriol placed in it and stirred until water is blue. Then one of the copper strips should be covered with the beeswax or paraffin over a little larger space than the impression is to be. The wax should then be rubbed with the powdered graphite until shiny, care being taken to get graphite around the edges. The impression should then be made by placing the letters, etc., backwards. The wax should then be dusted with the graphite so the impressions will be covered. Then all parts of the strip not wanted in the type should be coated with the wax. This strip may then be fastened to the negative or zinc pole of a series of batteries and the plain strip to the positive or carbon pole. Three cells of battery

Making Small Electrotypes.

should be conneced in series to do the plating. The two strips should be placed in the solution about ½ inch apart, so that the impression faces the copper strip. They should be left in the solution about 36 hours, after which the electrotype may be taken from the wax by a thin-bladed knife. If desired, the electrotype may be backed with solder or other metal to make it more substantial. Contributed by

KENNETH SUTTON.

WRINKLES — RECIPES — FORMULAS

Edited by S. GERNSBACK

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

FORMULA NO. 12.

Varnishes.

Varnishes (common Oil Varnish).—*Resin,* 4 lbs.; *Beeswax,* ½ lb.; *Boiled Oil,* 1 gal. Mix with heat, then add *Spirits of Turpentine,* 2 quarts.

Chinese Varnish.—Mastic, 2 oz.; *Sandarac,* 2 oz.; *Rectified Spirits,* 1 pt. Close the Matrass with bladder with a pin hole for the escape of vapor; heat to boiling in a sand or water bath, and when dissolved strain through linen.

Mastic Varnish.—Mastic, 1 lb.; *White Wax,* 1 oz.; *Spirits of Turpentine,* 1 gal. Reduce the gum small, then digest it with heat in a close vessel till dissolved.

Turpentine Varnish.—Resin, 1 lb.; *Boiled Oil,* 1 lb. Melt, then add *Turpentine* 2 lbs. Mix well.

Pale Varnish.—Pale African Copal, 1 part; fuse. Then add hot *Pale Oil,* 2 parts. Boil the mixture till it is stringy; then cool a little, and add *Spirits of Turpentine,* 3 parts.

Lacquer Varnish.—A good lacquer is made by coloring *Lac Varnish* with *Turmeric* and *Annatto.* Add as much of these two coloring substances to the varnish as will give the proper color; then squeeze the varnish through a cotton cloth, when it forms lacquer.

Gold Varnish.—Digest *Shellac,* 16 parts; *Gum Sandarac, Mastic,* of each 3 parts; *Crocus,* 1 part; *Gum Gamboge,* 2 parts; all bruised, with *Alcohol,* 144 parts. If yellow is required, use *Turmeric, Aloes, Saffron* or *Gamboge;* for red, use *Annatto* or *Dragon's Blood* to color. *Turmeric, Gamboge* and *Dragon's Blood* generally afford a sufficient range of colors.

Varnish for Tools.—Take *Tallow,* 2 oz.; *Resin,* 1 oz., and melt together. Strain while hot to get rid of specks which are in the resin; apply a slight coat on your tools with a brush, and it will keep off rust for any length of time.

Cabinet-Maker's Varnish.—Very pale *Shellac,* 5 lbs.; *Mastic,* 7 oz.; *Alcohol,* 90 per cent., 5 or 6 pts. Dissolve in the cold with frequent stirring. Used for French polishing, etc.

Waterproof Varnish.—The following is much used for waterproof textile fabrics: Boil together until thoroughly incorporated: 2 qts. *Linseed Oil* and ½ lb. *Flour of Sulphur.* Apply lukewarm.

Electrical Varnish.—The only good varnish for all kinds of electrical work, also for finishing wood and metal work, is formed by dissolving *Orange Shellac* in 95 per cent. *Alcohol.*

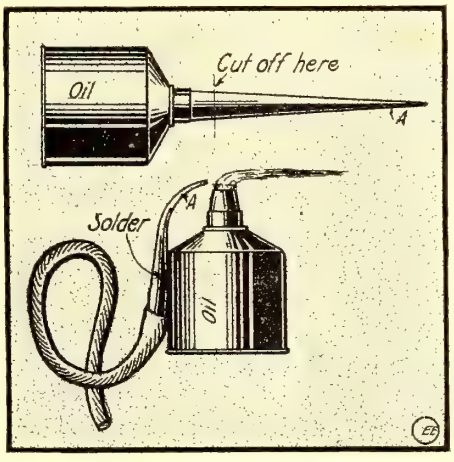
Mechanics Varnish.—Mix together: 5 parts of *Rosin,* 1 part of *Dragon's Blood,* 1 part of *Gamboge,* 2 parts of *Gutta Percha,* 1 part of *Shellac,* 40 parts of *Volatile Tar Oil.* S. G.

LINING FOR PLATING TANKS.

In pickling, plating and other metal treating processes the lining for the acid-holding tanks requires certain qualities to resist the corrosive action of the acids. A mixture consisting of 75 parts (by weight) of pitch, 9 parts plaster-of-paris, 9 parts ochre, 15 parts beeswax and 3 parts litharge is said to form an efficient lining for this purpose.

INK RECIPES.

(1) Black Writing Ink.—Take 6 ounces of the best gallnuts and pound them in a mortar or otherwise. Take 4 ounces of logwood and let it be cut or ground into very small pieces; these, mixed with 4 quarts of rain water, must be boiled together until half diminished. Then take 2 ounces of copperas made into a powder, and 3 ounces of gum arabic; let these be also mixed and strained through a linen cloth. After this mixture has stood a few hours it may be written with.



(2) Green Writing Ink.—Dissolve 1 ounce of Hoffman's Permanent Malachite Green in 1 gallon of hot water; add a little gall and alcohol. Reduce with cold water to the required shade.

(3) Sympathetic Ink.—An ordinary solution of gum camphor in whiskey is said to be a permanent and excellent sympathetic ink. The writing must be done quickly, as the first letters of a word have disappeared by the time the last are written. Dipping the paper in water brings it out distinctly, and it becomes invisible again when the paper is dried. It can be brought out repeatedly without affecting its vividness. Contributed by

CHARLES ROSENTHAL.

A HOME-MADE BLOW TORCH.

A good blow torch for the purpose of soldering wire joints and numerous other things may be made as follows: Obtain an oil can similar to the one shown in the

Blow Torch Made from Oil Can.

sketch with a rather long spout. Cut the spout off about half an inch from the top of the can. Next curve it as shown and attach to the larger end a small rubber tubing about 1½ feet long. Solder the spout to the side of the can and pinch the small end of it together a trifle, in order to give a better draft. Place a wick in the can and some alcohol. When using, light the wick and blow in the tube, which will produce a very hot flame.

WENDELL L. CARLSON.

SOME MORE ELECTRICAL DEFINITIONS.

Incandescent bulb: An instrument which burns up your money and makes "light" of it.

Fuse: Something which works steadily most of the time, but which, like other human beings, will have a blow-out once in a while.

Switch: Something which can be put on and off; such as hair, etc.

Magneto: Machine which generates current (except when placed on an automobile).

Buzzer: An electrically operated mosquito.

Electricity: A substance well behaved as a rule, but sometimes quite shocking.

Rotating Field: Seen with varying frequency by some members of the electrical profession and is nearly always produced by a third bottle of "Scotch"; star connected.

Current: The fruit of the dynamo, carried on poles but not used for pies. Contributed by HAMILTON A. HOOPER.

BLUE PRINTS AND BLUE PRINTING.

Since the making of plans is so closely allied with practical work the writer thought that a few words on the manufacture and use of a blue print paper, which can be made and used by the ordinary amateur with excellent results, would not be amiss.

To begin with, procure some tough, well-sized paper, preferably of a good grade, also some citrate of iron and ammonia and red prussiate of potash (recrystallized) and make, separately, two solutions as follows:

Solution 1.—Citrate of iron and ammonia, 1 part by weight; water, 5 parts by weight.

Solution 2.—Red prussiate of potash, 1 part by weight; water, 5 parts by weight.

Mix the two solutions in the dark or subdued light, and apply to the paper with a camel's hair brush or, failing this, a sponge.

The paper is coated by passing the sponge lightly over the surface three or four times, first lengthwise and then crosswise, giving the paper as dry a coating as possible consistent with an even coating. The treated paper is then hung up to dry.

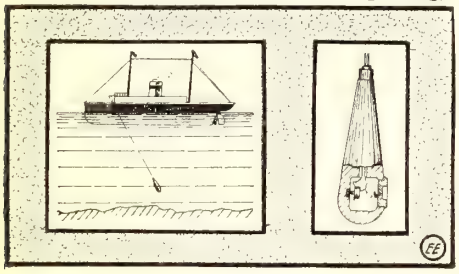
The above paper will require about five minutes to print. For a quick printing paper use a larger proportion of the citrate.

A blue print is made in a printing frame similar to that for printing pictures. The process is, briefly, to expose the tracing, with the blue print paper under it for a proper length of time, and then remove the paper and wash it in water. To print place the tracing with its face against the glass of the frame. Then lay the paper with its sensitized side next the tracing. The back of the frame is then clamped in position and the frame turned over so that the glass is up and the rays of the sun will fall on it at right angles. The above operations should be carried out in the dark or dim light.

When the exposure is finished remove the print, wash it in clear water and hang up to dry in the dark.

Should any lines or dimensions have been left out of the tracing they may be put in the print, using a solution of baking soda in water and an ordinary pen.

Contributed by J. L. GREEN.



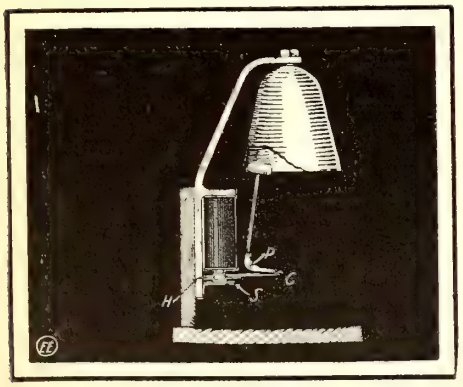
A NOVEL USE FOR HOSE CLAMPS.

Many amateurs connect the ground lead of their wireless to a water or gas pipe. The best method to do this is by using a ground clamp. The author, not having a ground clamp available, used a hose clamp instead. It is used in the same way as a regular type of ground clamp. These hose clamps may be had in sizes from ½ inch to 2¼ inches; the prices range from 2 cents to 9 cents, according to size.—Contributed by FRANK J. ZACHARIA.

If a voice were loud enough to be heard from New York to San Francisco it would take four hours to travel that distance through the air.

ELECTRICAL "SOUNDING" FOR SHIPS.

Believing that depth of water could be measured by mechanical and electrical means from shipboard, a series of experiments were recently conducted from a boat on the Ohio River. The principle adopted and on which the experiments were based was not unlike that of submarine signaling,



Electrical Device for Finding Depth of Water.

viz., if a sound could be produced on the bottom of the sea such as that caused by dragging a weight across a floor and then transmitted electrically to a telephone receiver at the ear of the pilot on shipboard, a means would be provided which would give warning of the vessel's approach into shallow water. With proper charts, giving speed of boat in knots, length of cable let out and depth of water in feet, it is quite practical to utilize this electrical "sounding" method, which has many advantages over the older method of lowering a weight until it reaches the bottom. A boat can move rapidly and readings taken just the same, says H. R. Gilson in *Electrical Review and Western Electrician.*

AN IMPROVEMENT IN ELECTRIC BELLS.

Considering their importance, electric bells have received singularly little attention, and the design remains substantially as when originally invented. The operation of the ordinary bell leaves much to be desired both from the electrical, mechanical and user's point of view.

A properly designed electric bell should have a hammer arranged to swing through an appreciable arc, while the contact should be made when the hammer is right back and broken only when the armature has come against the pole-pieces. A bell on these lines appears in the illustration. The

New Form of Electric Bell Said to Be Most Efficient.

armature is hinged at H, while the hammer is pivoted at P, the electric contact being at C. The armature rests against the stop S at the beginning of the stroke, while the hammer falls far enough backwards to make the contact C. Current flows through C when the circuit is completed, thereby exciting the magnets which draw up the armature with a jerk, so that the hammer is thrown against the gong and the contact C is also broken. The armature then falls back on to the stop S, and remains there until the hammer falls back and remakes the circuit when the cycle is repeated. The stop S is made springy, which materially increases the force of the blows. Owing to the fact that the contact is made when the armature is right back and not broken until it is against the poles, this form of electric bell is very efficient, while the slow and rhythmic stroke permits the use of musical gongs which ring out with pleasant tones. Laminated magnets give an appreciably sharper hammer blow, and should be used for large bells. The contacts may be made of nickel or similar metal, and are self-cleaning if the metal is thin enough to insure that the pressure is concentrated on a small area where they meet.—*The Electrician,* London.

ANNOUNCEMENT

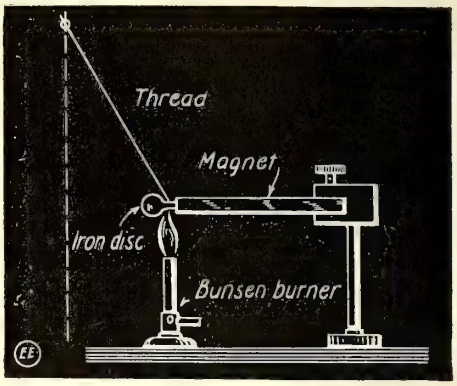
THE beautiful art supplement with which we present our readers to-day is the little surprise of which we spoke in our June issue.

While we feel proud of our August number, the September issue will eclipse it by far. To begin with, THE MAGAZINE WILL BE ENLARGED AGAIN, the fourth enlargement in five months. Many important new features will be found, all after your own heart. Yes, there will, of course, be another supplement, one over which our "How to make it fiends" will go wild! Then there will be a wonderful illustrated article on Radium, and last, but not least, you will find a rattling good short story in this number, which we know you won't pass up.

If you are not a subscriber, order the September issue without fail to-day, so your dealer won't tell you, "sold out." Also before we close, remember:

EXPECT MUCH

VOLTS FOR WOMEN.

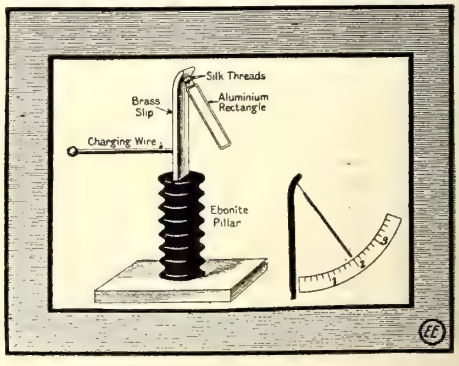


There may be some among our readers to whom the newspaper item about Policeman Ohm being put in a cell means very little. As for ourselves we merly inquire, "Watt for?" and whether he made much resistance. If so, he probably got hot about it. His attorney wanted him discharged, so he could light out. He lost his star connection. Somebody blew on him. Poor man.

EFFECT OF HEAT ON MAGNETISM.

An interesting experiment, depending for its action on the fact that iron when heated ceases to be magnetic, is here described.

A pointed disc of sheet iron is suspended by a thread and is placed with the point against the magnet, which holds it there by attraction. A flame is allowed to burn under the point, which when heated strongly is no longer attracted by the magnet, and therefore swings away. By the time that it has completed its swing it has cooled sufficiently to be attracted again by the magnet.



The iron, becoming reheated, swings away again and the cycle of events is repeated. The iron disc should be large enough to cool by radiation sufficiently (during the swing) to become magnetic again, says a writer in *Model Engineer.*

Demonstrating the Effect of Heat on Magnetized Iron Disc.

ELECTROSCOPE FOR LECTURE TABLE USE.

In his recent lectures at the Royal Institution on photo-electric phenomena, Dr. J. A. Fleming made use of an ingenious form of electroscope which he has devised for lecture purposes. In Dr. Fleming's electroscope a slip of brass about 0.25 inch wide and 2 inches long is fixed vertically on the top of a corrugated ebonite or sulphur pillar. The top of this metal slip is slightly bent over. A rectangle made of fine aluminum wire of nearly the same width and length as the slip of metal is attached by two very short cocoon silk fibers to the top of the rectangle, and these fibers are wetted with a solution of chloride of calcium to make them conduct. When the system is not charged the rectangle hangs vertically in contact with the metal slip. If a charge is given to it the rectangle stands out at an angle as seen. It is essential that all edges of the metal shall be carefully rounded so as to leave no sharp points. To the back of the metal slip may be attached a thin wire ending in a small ball, which is convenient for making contact with electrified objects. For lecture purposes the image of the electroscope can be projected on the screen by placing it in

Large Lecture Table Electroscope.

a parallel beam of light and employing a projecting lens and correcting prism. Dr. Fleming employs as a screen a large sheet of paper, on which a curved arc divided into degrees is drawn, as depicted at right of sketch. The radius of this arc is adjusted to be the same as the length of the image of the aluminum rectangle, so that the end of that image moves over the arc, as apparent.—*The Electrician,* London.

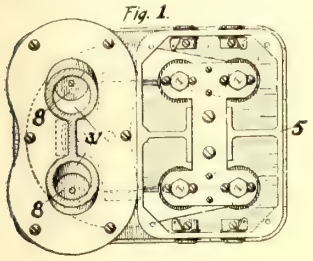
LATEST PATENTS

Telephonic Relay or Amplifier.

(No. 1,140,366; issued to Henry C. Egerton.)

A rather novel form of telephonic relay or amplifier arrangement, comprising, as shown, a soundproof case, 5, containing in

Fig. 1.



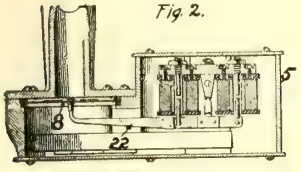


Fig. 2.

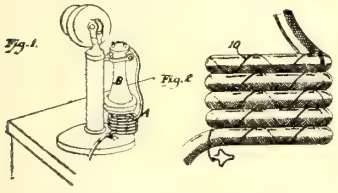


two divided compartments of same two distinct sets of polarized electro-magnetic mechanisms with pivoted armatures 22, as observed. One side of a telephone line is connected with one set of electro-magnets and the vibrations of their armatures vibrate in turn a diaphragm 8. This sets up (acoustically) air vibrations in the return air chamber 31, causing the second diaphragm 8, on the other side of the case, to begin vibrating synchronously. When this second diaphragm starts vibrating it also moves its attached pivoted armature, and this sets up periodical changing electric currents in the second set of electro-magnetic windings, which connect with the second part of the circuit, etc.

Telephone Cord Coiling Device.

(No. 1,140,980; issued to Lorenzo E. Haynes.)

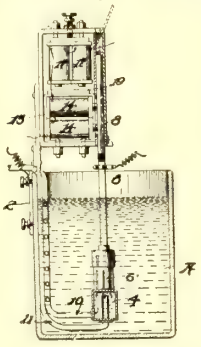
We are all more or less familiar

with the troublesome telephone receiver cord, which is forever getting tangled up with something or other. This inventor causes the cord to automatically resume a spiral coil form, very compact and neat, as the illustration shows. A steel wire 10, specially coiled, for instance, is suggested to be secured on the telephone cord "A," causing the action just explained to take place automatically when the receiver "B" is hung up.

Improved Dry Battery.

(No. 1,140,826; issued to William Hoppie.)

Concerns improvement in the manufacture of electric dry cells with the object in view of providing a battery device having improved means, whereby the life of same may be materially lengthened. Further the invention relates to the

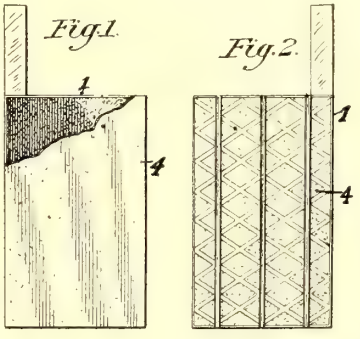


use therein of mercury and aluminum, which are decomposed by chemical affinity and the metallic atoms electrolytically deposited on the zinc, protecting thereby and prolonging the life of the zinc, making it a more active element and generating a higher electro-motive force. Several other improvements are covered in the patent, such as improved container, insulation and non-buckling features for same.

A Magnetic Oscillation Generator.

(No. 1,142,496; issued to Alfred H. Cohen.)

A magnetically operated oscillation generator, intended to be used in a wireless transmitting circuit for producing radio-frequency oscillations directly. The main circuit current is broken in an insulating bath "A" in a container 2. The lower electrode 4 is water-cooled, as also the bath, by suitable tubes 10 and 11. The upper electrode 6 is raised by a peculiar magnetic system 14 and 17. The upper electrode 6 is joined to an iron lifting rod 8. The electro-magnets 14 first act on this rod and an instant afterward the upper set of electro-magnets 17, 17 attract an iron armature 19 on the movable magnet frame 13. By this compound magnetic action the patentee claims to be able to synchronize and properly tune up a set of these interrupters operating in series, etc., so that they will work to a maximum efficiency in a perfect manner. They are intended to be hooked up directly across the dynamo circuit and to have a capacity and induct-



ance shunted across the gaps here described.

Storage Battery Plate.

(No. 1,141,251; issued to Joseph O. Luthy.)

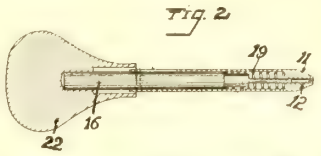
A novel method of improving storage battery plates and to prevent the active element of same from disintegrating or peeling off. This patent covers a process for coating the outside of the battery plate 1 with a porous, enamel-like

coating 4 which, it is claimed, does not lower the efficiency of the battery in any way or introduce any undue resistance, as proved by actual tests. A method is also mentioned for improving this process by having the enamel coating supported on a fine mesh screen. It is claimed that this patent absolutely prevents the active element of the plate from falling out or becoming damaged otherwise, electrolytically (? *Editor.*)

A Magnetic Brad-Set.

(No. 1,141,073; issued to Charles H. Parks.)

Fig. 2.



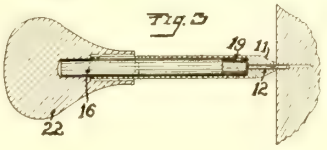


Fig. 3.

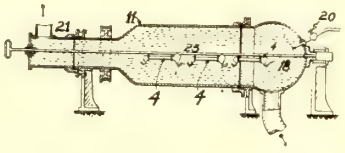
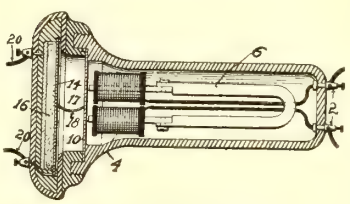


Another practical application of magnetism. In this particular invention there is provided a magnetized steel bar 16, which is repelled out of the hollow barrel 11 by a spiral spring 19 within the barrel. Small iron brads, etc., are held within the opening of the barrel 12 by the magnetized stem of the steel rod. By exerting a sharp, quick pressure on the ram head 22 the brad is driven home.

Ultra-Violet Ray Water Purifier.

(No. 1,140,819; issued to Victor Henri, André Helbronner and Max von Recklinghausen.)



A new form of ultra-violet ray device for water purification purposes. Ultra-violet ray tubes 4, such as quartz mercury vapor lamps, are mounted on a suitable support 8 within a rotatable water chamber 11. In operation this chamber is filled with water from the inlet 21 and when full the chamber 11 is rapidly rotated. This causes the water at the center, by centrifugal force, to leave a vacuous space at the center, as indicated by the dotted line space 23. Thus the water does not come in contact with the tubes, yet the rapidly swirling mass of liquid is thoroughly permeated by the ultra-violet ray and thus sterilized. The air space 23 may be varied as to size by admitting more or less compressed air through pipe 20.

Simple Telephone Repeater.

(No. 1,143,173; issued to Gustavus A. Janicke.)

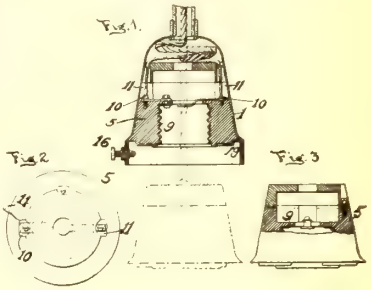
A very simple form of telephone repeater or amplifier whereby the telephonic currents enter terminals 2, joined to the usual electro-magnetic coils 4, mounted on permanent magnet 6. In front of their pole pieces is a diaphragm 10, connected by a metallic wire 18 with a second diaphragm 14, behind which are carbon granules forming a microphone 16. The space 17 between the two diaphragms 10 and 14 is air-tight, so that each diaphragm can vibrate independently of the other, as the wire 18 is flexibly

joined to the diaphragms. The secondary circuit of this repeater or amplifier is joined to the wires 20, connecting with the microphone.

Electric Soldering Iron.

(No. 1,142,306; issued to John G. Clemens.)

A distinctly novel form of electric soldering iron, quite different from the usual form we are familiar with. This device is arranged to pass electric current through one of its electrodes 11, through the wire joint to be soldered and thence back to the second electrode 12. The patentee mentions that it is best to make these electrodes 11 and 12 of some high resistance material, such as German silver, etc., so as to cause as much heat as possible to be generated by the passage of the current through these parts. Also, no solder is used on the "iron"

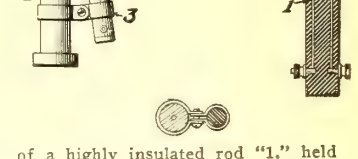


proper, as is the case with ordinary soldering coppers.

Improved Lamp Socket.

(No. 1,140,498; issued to Charles L. Cassidy.)

The inventor of this electric lamp socket has endeavored to make it



as simple as possible from the manufacturing point of view. The shell "1" is made from one piece of stamped metal and, as the dotted lines show, the interior insulation plug "5" carrying the lamp base contacts "9, 10, 11" slides forward when the three retaining screws "16" are removed. The plug "5" is held in place by a flanged ring "19." The screws "16" hold this ring in place and also secure lamp shades or reflectors. A promising patent.

Electrical Head-Lamp Igniter.

(No. 1,139,759; issued to Francis N. Fox.)

This patent covers construction

of a highly insulated rod "1," held in a suitable clamp "3" and which rod carries two distinct electrodes "9," which have between their upper free ends, a spark gap of short length. A regular high tension ignition coil can thus be connected to these two insulated sparking wires "9" and it is thus possible for the owner of gas head-lamps to light them from the seat of his automobile.

(Copies of any patent above mentioned supplied at 10 cents each.)

AMONG THE AMATEURS

AMATEUR RADIO STATION CONTEST.

Monthly Prize, $3.00.

This month's prize winner.

JOHN J. GROSSMAN'S WIRELESS STATION.

Herewith is photo of my wireless station, which I should like to appear in your valuable magazine.

Views of Mr. Grossman's Wireless Station and One of the 70 Foot Aerial Masts. Also a Likeness of the Owner of This Very Efficient Plant Appears Below.

This station made some records in the past winter, having worked with the University of North Dakota, 920 miles; with Northampton, Mass., and 8 O. Z., Kane, Pa., several times. We are a *sure link* in the American Radio Relay League and the Central Radio Association, as we have two operators and are "in" right along. An Audion set is used for reception.

Tiffin, O. JOHN J. GROSSMAN.

E. C. WAIDLER'S LABORATORY.

Herewith is photo of my wireless outfit. It consists of a ½-K.W. transformer with meters, regulators and an air-cooled gap. The receiving set is composed of a Ferron

E. C. Waidler Busy in His Wireless Laboratory.

and Perikon detector, two fixed condensers and a Blitzen variable condenser, a loading inductance of 3,000 meters' capacity and a receiving transformer of my own make.

My aerial is composed of six copper-clad wires on 12-foot spreaders, and is 75 feet long by 80 feet high. I get Arlington every night and sometimes I hear Key West and Colon. I also use a Geissler tube for a radiation tester and it works very satisfactorily. I think your magazine is excellent.

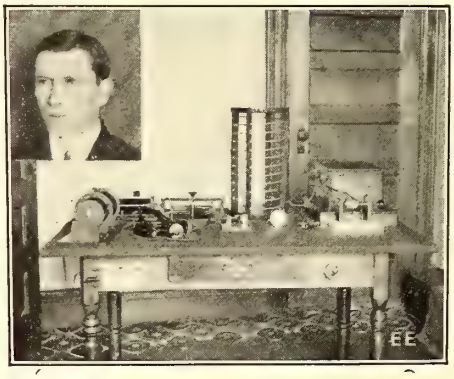
E. C. WAIDLER.

East Toledo, O.

Beech's Wireless Installation.

Herewith is presented the radio station of Guy Beech, of Clarinda, Iowa. The sending set comprises the following instruments: One-quarter-inch Bulldog spark coil, key, home-made condenser, helix and spark gap. The receiving outfit is com-

Guy Beech and His Radio Outfit.



posed of a 75-ohm receiver galena detector, "junior" fixed condenser and tuner.

Good results are obtained with this set and Arlington and (I. W. Co.) Illinois Watch Co. can be easily heard.

Clarinda, Iowa. GUY BEECH.

HOOVER WIRELESS PLANT.

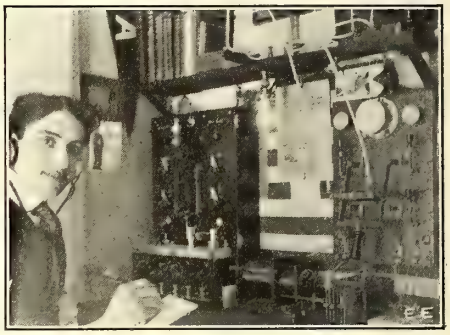
The receiving set of my wireless outfit consists of a loose coupler made from a design given in Modern Electrics. A variable condenser, Brandes' navy 'phones loading coil and perikon detector, from crystals furnished by Electro Importing Co. The sending set is a ¼ K. W. closed core transformer, with glass plate condenser, helix, key and spark gap. I use a sending wave of 190 meters. I notice only about two out of ten amateurs seem to

Raymond Hoover and His Neatly Arranged Wireless Set.

have a Government license; I would like to see all the amateurs get a license, it is so easy to procure. They only try you in one wireless code, and very slow. Also the questions asked most any amateur knows. My call is "2 L. Y."

RAYMOND HOOVER.

Newark, N. J.



To find the approximate wave length of radio aerials multiply the total length of aerial in meters by 4.5.

ANTONE SYLVIA'S STATION.

I give you herewith a photograph of my wireless station for publication in your magazine. The station comprises the following:

Two loading coils, a loose coupler, one sliding plate variable and a Clapp Eastham rotary variable, two fixed condensers, one silicon detector and one Perikon, one pair of Brandes' 'phones, transatlantic type, and also one pair of Brandes' navy type. The cabinet set was designed and built by myself. I use an inside antenna and get good results.

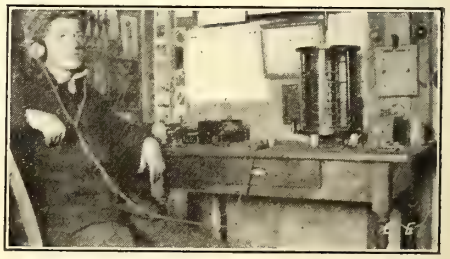
Sending outfit includes Mesco 1-inch spark coil, spark gap, a Clapp Eastham ¼-K.W. helix, one section of Murdock condenser and Mesco key mounted on a

Mr. Antone Sylvia's Excellent Radio Station.

marble base. The station also has a switchboard, seen at the right, which contains all the necessary switches to operate the station.

The microphone seen in the picture is used for wireless telephone experiments and, using the inductive system. I have talked about four blocks away, or 518 feet, to be more exact.

I have read your magazine and find it valuable for radio experimenters.



ANTONE SYLVIA.

New Bedford, Mass.

RADIO SET OF F. F. DENNIS.

Below is photo of myself and my radio receiving and sending apparatus. My aerial is 135 feet long and 60 feet high, and consists of five wires 2 feet apart. My receiving apparatus consists of one double-slide tuning coil, one E. I. Co. single-slide tuning coil, one fixed condenser, a galena detector and one pair of Brandes' 2,000-ohm superior 'phones.

My sending apparatus is composed of a 1-inch spark coil, one home-made condenser, Mesco key, large home-made helix,

Wireless Signals Coming in at Station of Fred Dennis.

zinc spark gap, 10 dry cells and a three-pole double-throw switch. The receiving range is about 600 miles at night.

I would be pleased to talk to any amateur within by range, or will be glad to hear from anyone. My call is 2 J. T.

Fair Haven, N. J.. FRED F. DENNIS

Phoney Patents

Under this heading we will publish hereafter electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore announce the grand opening of the

PHONEY PATENT OFFIZZ

For the relief of all suffering daffy inventors in this country as well as the entire universe.

We will revolutionize the Patent business immmediately and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of examiners to issue a Phoney Patent on your invention in a jiffy.

PHONEY PATENT OFFIZZ

A. WALL-EYED PIKE, OF MOMBASHIA, N. Y.

No. 41144¼ (For Luck) **FISHERMAN'S DELIGHT** **Patent not Applied for June the foist, 1915**

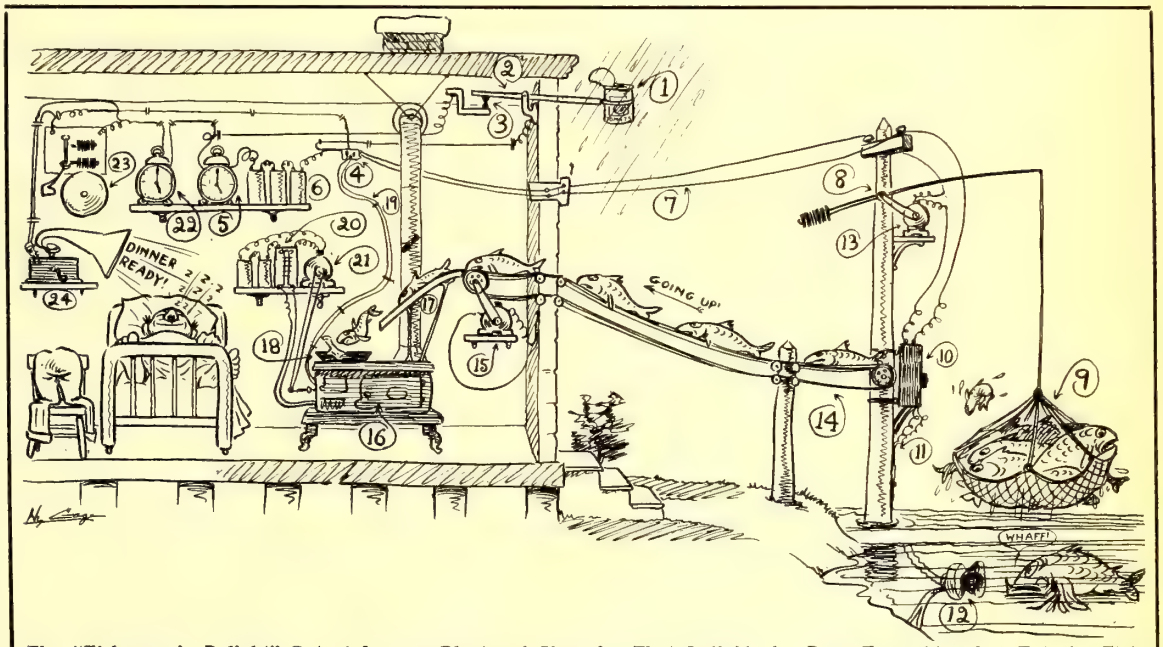
Specification of Phoney Patent
Application junked December the onc't, 1890½

To Those Whom It May Not Concern:

I, Wall-eyed Pike (note the hyphen), of the Principality of Mombashia, N. Y., have invented means whereby the *sadly neglected fisherman* has come into a heaven of his own, by virtue of my marvelous invention, which shall be known hereinafter, henceforth and ever after, as the "Fisherman's Delight."

Just why the fisherman, on whom we all depend at times for food, has been so sadly neglected by the numerous inventors of our marvelous age is hard to reason out, and therefore I have devoted my best energies in perfecting an invention, so devised that when the tired fisherman is at home he can have all the peaceful slumber he cares to indulge in, without having to arise early in the morning, or in fact any time in the morning, to catch a mess of fish for dinner.

In further description of this infamous scheme, the reader is referred to the hieroglyphical sketch, and the various parts are numbered to correspond with inscription given below: To begin with, the basic part of this wonderful invention, albeit, centers on the rain-catching tripper 1. On a fine rainy morning, the "Tomato can" fastened to switch lever 2 soon becomes filled with water, opening the lever switch contacts 3. Thus the electrical circuit 4 is prevented from operating when the alarm clock 5 operates in the early hours of the morning. If it is a bright, fair morning the lever switch 2 remains closed, and when the clock 5 goes off it closes the electrical circuit 4, by means of battery 6 and wires 7, to start operating an electrically driven rising and falling baited net mechanism 8. The net is depicted at 9.



This part of the apparatus may seem somewhat hazy to the uninitiated, and so we hasten to explain. At 10, on one of the wooden piles supporting the fish-catching parts of the perfected "Fisherman's Delight" machinery, is mounted an automatic electrical relay device, which is hooked up with a couple of heavy insulated wires 11 to a very sensitive microphone 12. Now this device is so arranged that when the clock 5 closes the circuit 7 in the morning, the electric motor 13 moves the lever 8, to lower the net 9 into the water. As this net should not be raised until filled full of fish, of course, some arrangement must be provided that will close the circuit of the motor 13 again to raise the net only when the fish have entered same.

I duly provide for this function by means of a sensitive microphone 12 (which has been used by fishermen for some years to "hear" fish approaching). When the school of fish approach the baited net their swishing about in the water sets up sounds, and these strike the microphone 12, which communicates them electrically to the relay 10, and so the net is raised into such a position that it ejects the fish on to the moving belt conveyor 14, which is driven in the house by an electric motor 15, whose circuit was closed by the clock 5 when it first went off in the morning. This belt conveyor is always moving and carries the fish into the house, and when they near the stove 16 they are precipitated through an inclined shute 17 into the frying pan 18.

The fire in the stove 16, which may use wood, coal or oil, etc., is to be started by electric current through the wires 19, joined on to the circuit 7 from the clock 5. When the fish have been fried sufficiently and, conjointly, when the fire has burned to a sufficient degree of heat, it will cause a thermostat 20 to operate an electric motor 21, which will close the damper or regulator of the stove.

This whole arrangement is, of course, to be so proportioned and designed when practically installed, that all of the foregoing operations will take place in the forenoon and at dinner time the alarm clock 22 will then operate, and should the fisherman not hear the ordinary bell, it is arranged to close a circuit through a **12-inch** fire alarm gong 23.

A somewhat more gentle awakening device may be provided, if preferred, by utilizing a talking machine 24, electrically actuated or started from a circuit such as that connected to the gong 23. Some folks prefer to be awakened according to the latest scientific theories, or by music; and so a musical record may be placed on the machine, or if the announcement, "Dinner Ready!" is preferred, then a specially prepared record may be made with a continuous rapid-fire string of such words on it.

The "Fisherman's Delight" Patent Insures Plenty of Sleep for That Individual. Does Everything but Eat the Fish.

In testimony whereof I have hereunto scrawled my name this foist day of December, 1890½.

A. WALL-EYED PIKE.

By his attorney:

S. W. Healy, Troy, N. Y.

Witnesses:

A. DILL PICKLEFRESSER,
I. M. A. HELGAMITE,
A. BLACK BASS.

Chappie—"Electricity is wonderful. I tell you it weally makes one think."

Miss Cutting—"Yes; why don't you get a battery?"

QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:

1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

RADIO LAW AND WAVE LENGTH.

(294) C. Howard E——, Sandwich, Mass., asks several questions relative to the wireless law, etc.

A. 1. We are pleased to advise you as follows regarding your radio queries:

The matter of a wireless license, as required by the radio law now in effect, is explained in detail in papers procurable from your local radio inspector; address care of Custom House, Boston, Mass.

This law requires that where an amateur is to transmit wireless messages his radiated wave length shall not exceed 200 meters in value.

Also with regard to the latest rulings with respect to the U. S. radio law and experimental radio-transmitting stations, would say that where the amateur radio-transmitting station is located so far inside the State border line that it cannot transmit over the border line no Government license is required, ordinarily. However, if this station can interfere with the transmission and reception of commercial or Government radio messages over that State border line, then the amateur transmitting plant must have a license, and this decision has been handed down recently in several court cases.

STORAGE BATTERIES.

(295) William A. Collins, Philadelphia, Pa., writes us regarding storage battery capacity, lamps to be used, etc.

A. 1. The usual discharge rate for 6-volt 60-ampere-hour storage battery is about eight hours, or in other words, about seven to eight amperes for that period.

As the volts times the amperes give the watts used in the circuit, you can readily, of course, figure out how many lamps you can operate of any type you are interested in, figuring 1 watt per candlepower for the battery-type tungsten lamps.

LIGHTNING RODS vs. WIRELESS.

(296) Clifford Pinkerton, Spencer, S. D., wishes to know whether lightning rods on a building will affect a radio antenna on the same building.

A. 1. Lightning rods, of course, will have some effect on wireless aerials, as they tend to dissipate some energy in the earth.

However, they are generally of relatively small area as compared to the large metallic spread of the antenna, so that they do not have such a great effect as might be imagined. This refers to either indoor or outdoor aerials. Also the aerial proper should be placed as far as possible from such conductors.

SPARK GAP QUERIES.

(297) C. D. Blair, Richmond, Va., wants data on best form of spark gap to be used on radio transmitter, employing electrolytic interrupter, so as to give the highest pitch possible.

A. 1. You can improve the tone or pitch of your spark by using a quenched gap. It is not usually beneficial to use a rotary-type gap with electrolytic interrupter, as the interruption frequency is not regular enough.

Hence to realize the best results with a variable frequency in the primary you should use a quenched gap, as this form of gap will operate on any frequency very nicely, and it makes practically no difference in the design of the gap whether 60 or 500 cycles are used in the transformer primary circuit.

We believe this to be the best solution of your problem, and of course you can raise the spark tone some by careful adjustment of the electrolytic interrupter anode.

RECEIVER GIVES SOUND WITHOUT DIAPHRAGM.

(298) A. B——, Amboy, Ind., inquires for construction data of 3,000 meter loose coupler.

Want to Swap?

If you have anything to buy, sell or exchange and want to make sure of doing it quickly and at an insignificant cost advertise in the

Scientific Exchange Columns
OF
The Electrical Experimenter

You will find advertised in these columns:

Photographic supplies, Phonographs, Wireless Apparatus, Electrical goods, Bicycles, Motorcycles, Rifles, Gasoline Engines, Microscopes, Books, Skates, Typewriters, Etc.

The owners of these things wish to ***"swap"*** them for **something else, something which you may have.**

The Rates

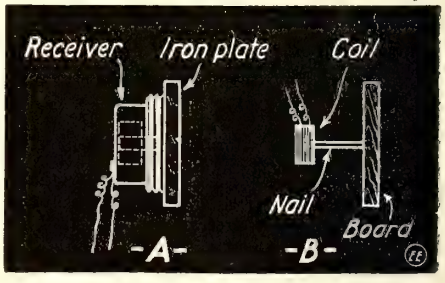
One cent per word (name and address to be counted) minimum space 3 lines. Average 7 words agate to the line. *Remittance must accompany all orders.*

The Classified Columns of the ELECTRICAL EXPERIMENTER GET RESULTS

More than 35,000 Electrical Experimenters will see your ad.

A. 1. You will find this data, with complete working drawings, given in the March, 1914, issue of this journal.

A. 2. As far as we know, a person holding a commercial radio license can obtain a position in a land radio station without first serving at sea.



A. 3. We are very much interested in your experiment whereby you cause a telephone-receiver shell and magnet only, without any diaphragm and cap on same, to give forth a sound as usual.

This matter has been explained in several ways from time to time, and as near as can be judged from the various theories and explanations regarding it, it is based on the change of the molecules making up the iron core in the receiver. We should imagine that with a receiver connected across the vibrator of a buzzer, as in your case, the sound heard in the receiver would be naturally more pronounced than if speech were being reproduced, owing to the fact that the buzzer *make and break impulses* are very strong.

We give herewith sketch showing how a very interesting experiment can be made by means of a telephone receiver without the usual diaphragm. We may say, before going further, that in all these experiments it has been found best that the coils shall be wound rather loosely, but not necessarily so loose that the turns can jump about or vibrate.

In the sketch a peculiar experiment is shown at "A," where a thick iron plate, which may be as thick as 1 inch, is placed in front of the receiver and the magnet coil and the pole piece of same acts on this plate. Speech has been reproduced in this way, and of course, as it is impossible for the small receiver to vibrate the whole plate by bending it in the way the diaphragm of 1/64-inch iron does, the iron must vibrate in unison with the speech waves, etc., by molecular vibration.

Regarding the exact theory of how these molecules become magnetized and demagnetized so as to manifest this change in their condition physically, this is not very

Telephone Receiver with Thick Iron Diaphragm at A; Board Reproduces Speech When Arranged as at B.

well defined. It has been pointed out by several authorities such as Silvanus P. Thompson, of England, that a *magnetized* steel bar is longer than when it is *not magnetized.* He has also stated that a definite click can be heard when the bar is magnetized and demagnetized, and he says theoretically that this is undoubtedly due to the fact that the molecules when magnetized tend to set themselves, end to end, and thus the steel bar is lengthened.

It may be said that in such experiments with solid iron plates or bars having coils mounted on them to create speech without the usual diaphragm, the iron used is always best of very soft or cast stock, and steel works very poorly, if at all.

At "B" in the sketch is shown another experiment of interest where the receiver magnet coil has inside it an iron nail with, preferably, a good, large head on same. The nail is driven into a piece of board as shown. If this board is held against the ear, it will be found that the speech can be heard all right, as well as if a regular receiver were used, but of course not quite as loud. The board acts probably as a sound-resonator.

FATAL SHOCK FROM TELEPHONE WIRES.

(299) William F. M., Jr., Cleveland, O., says he has read of people having been electrocuted by coming in contact with telephone circuits, and wishes to know how this is possible.

A. 1. It has happened a number of times that people have been electrocuted by coming in contact with telephone wires where there seemed no possibility of such a thing happening.

It has usually been found the case, however, when such fatal results have occurred, that the telephone circuit with which the person came in contact was crossed, perhaps temporarily, due to a broken wire, etc., by a high-voltage lighting or power wire carrying several thousand volts.

It is readily seen, then, that a person coming in contact with the telephone wire so charged would, in many cases, complete a circuit to earth through his body, and undoubtedly fatal results would obtain.

The fuses you speak of in the telephone circuit would not be of any benefit in such a case, for the reason that the current of dangerous potential would be several thousand volts and the current in amperes would only have to be a fraction of an ampere to prove fatal. Then again, it is quite possible that the circuit through the body would be made over a full metallic circuit in which no fuses were inserted.

1,000 AND 75 OHM TELEPHONE RECEIVERS ON ONE CIRCUIT.

(300) A. E. Eichner, Trenton, N. J., is using a 75 and a 1,000-ohm telephone receiver on a common circuit, and wants to know why they don't talk good, telephonically.

A. 1. The reason why you cannot get good results using the 1,000-ohm receiver is due to the fact that the voltage generated by the movement of the diaphragm in either case is not correctly proportioned to operate the opposite receiver, owing to the different number of turns on each coil, etc.

In other words, you will appreciate that if, for instance, the voice waves operate or move the diaphragm of the 75-ohm receiver, currents will be generated in the magnet coil of same which will have only a few volts potential, with a comparatively large current value.

These currents, of course, when they reach the high-resistance receiver with many thousands of turns of wire on it at the other end of the circuit, cannot operate same efficiently, as such a high-resistance receiver is suited to, relatively speaking, high voltages with small current values, and vice versa.

You will readily understand how the 1,000-ohm receiver would have generated in it currents of much higher voltage, of course, than a 75-ohm receiver with a consequent very small current value, and as the 75-ohm receiver, as we know, requires a relatively low voltage with a strong current value, the current passing over the circuit from the 1,000-ohm receiver will not operate efficiently the 75-ohm instrument at the opposite end of the line.

You will always find in this sort of work, as well as in most telegraphic circuits, etc., that the instruments should approximately be balanced to each other as regards current, voltage and resistance ratings.

BUZZER INDUCTION CURRENTS.

(301) Wynn Boyden, Medina, O., states that he has been able to transmit radio signals by a buzzer, and asks why it is

$25.00 to $75.00 SALARY WEEKLY

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large—promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

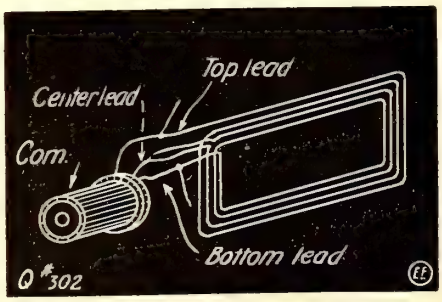
Present Occupation _____

that the same results are obtained whether the aerial and ground are connected across the vibrator or across the whole buzzer circuit.

A. 1. In regard to your wireless transmission by buzzer, would say that it is generally found that practically the same results are obtained whether the ground and aerial wires are joined directly across

Showing Buzzer Connected in Two Ways to Aerial and Ground.

the buzzer vibrator, as diagram A shows, or across the whole buzzer-induction circuit, as indicated at B.



In any case, the increase of voltage in the circuit by self-induction whenever the vibrator breaks the circuit will be evidenced throughout the circuit, and is bound to charge the aerial and ground conductors whether one of these wires is joined ahead of the magnet coils in the circuit or behind them, due to the reason that the self-induction surge in the circuit passes throughout the whole circuit, roughly speaking.

ARMATURE WINDING.

(302) Gilbert M. M———, Savannah, Ga., asks us about hooking up leads from a motor armature which has one-half as many slots as commutator bars.

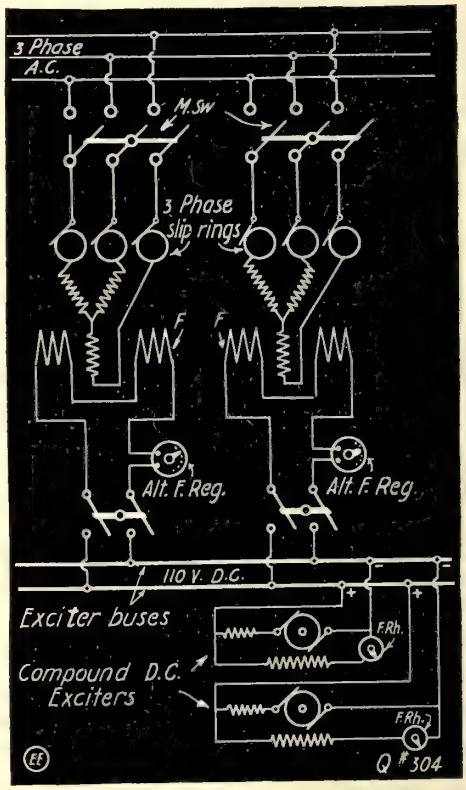
A. 1. Regarding the winding of small D. C. motor armature containing twice as many commutator bars as slots for winding, the diagram will help to show how this is usually done, especially on small armatures such as those used in fractional horsepower motors of the fan type.

As you will see from the diagram, there is a loop or lead left out in the middle of each coil as it is wound, lap-fashion, and thus each coil will have three leads projecting from same, and for small armatures it is common practice to place the central lead half way through the coil as regards the number of turns in the coil. For instance, if the coil had two hundred turns of wire in it, at the 100th turn the center or looped lead should be left out. In other words, this lead would be left

How Armature Coils Are Tapped by a Middle Lead When Twice as Many Commutator Segments Are Used as Slots in Armature.

extending several inches. With such complicated windings it is always invariably the best policy to mark these center leads in some way with a piece of string, etc., so that when joining the leads to the commutator the proper sequence will be followed without any trouble. Otherwise the coil is liable to be connected to the commutator backward.

ELECTRICAL PLANT CULTURE.



(303) Alan E. Simmons, Palmetto, Fla. We do not know just what arrangement you intend to use, but from what we know of the matter of electrical plant culture it may be said that a regular spark coil and high-frequency set is generally utilized for the purpose.

Also it would be possible to utilize a closed-core wireless-type transformer giving a high voltage at the secondary, such as a ¼-K.W. unit, developing 10,000 to 12,000 volts.

High-frequency current could then be produced by means of this transformer and a suitable helix and condenser in the regular way.

PARALLEL OPERATION OF TWO A. C. GENERATORS.

(304.) Mr. C. O. W———m. White Plains, Ky., asks us about a problem he has relative to parallel operation of two A. C. generators, also several other queries.

Suggested Hook-Up of Two Exciters and Two 3-Phase A. C. Alternators to Give Steadiest Operation.

A. 1. With reference to the parallel operation of two 75 kilowatt, 60-cycle, 220-volt, 3-phase A. C. generators would say that the special diagram you show where exciter No. 1 is hooked up with the rotating field winding of alternator No. 2 and exciter No. 2 with alternator field No. 1 is quite practical and has been used considerably in practice so as to help keep the two machines driven from separate engines in as nearly as possible strictly synchronous relation.

This arrangement, however, has a bad disadvantage in that if one of the alternators should for some reason be shut down quickly it would affect the *exciter* of the *second alternator;* and thus the whole plant will be shut down. This naturally would be a bad state of affairs.

(*Continued on page* 170.)

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we will publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Questions addressed to "Patent Advice" cannot be answered by mail. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

Applying for His Own Patent.

(6) Benjamin Hurst, Los Angeles, Cal., would like to know if it is feasible for him to make his own patent application at the Patent Office instead of engaging a patent attorney to do the work.

(A.) While quite a few people prosecute their own patent business and apply for patents themselves instead of through a patent attorney, we would advise that unless the would-be applicant is an attorney himself or knows legal phraseology, not to attempt it, for he will be sure to overlook the most vital points. It is not enough to just describe your invention and send in a drawing showing what the idea consists of, but the most important part in a patent is the "claim." These claims, which make a patent valuable, are quite technical and the average layman does not as a rule understand the language used in them. Where the layman could usually not find more than two or three claims to a given patent, an experienced patent attorney will easily find from ten to twelve, and while the Patent Office may not allow all the claims, they certainly, as a rule, will allow more than the layman could make up.

In our opinion it is always best to engage a reputable attorney to obtain a patent and while the cost may be greater, on the other hand, the protection is vastly greater also. It has, as a rule, a certain value which the same patent obtained by the untrained layman would not have.

Cost of Patent.

(7) Edwin P. Powell, Red Bank, N. J., desires to know how much it would cost him to patent an invention.

(A.) A patent can be obtained for as low a price as $50 from reputable patent attorneys if the invention is a simple one and does not require more than one sheet of drawings and if it is not too complicated.

If a long search in the Patent Office is necessary in order to convince the attorney that it is safe to go ahead with the application it must be, of course, understood that such extra work must be paid for. As a rule it would be safe to say that simple patents with one sheet of drawings would not come higher than $75 with most reputable attorneys. If the patent is extremely complicated and has many sheets of drawings the cost will, of course, be much higher.

We would advise correspondents to send for all literature of patent attorneys and ask for their fees. Most of the attornevs get out attractive booklets that very often contain valuable information which the inventor who is interested in patents should possess by all means.

Can He Trust Attorney?

(8) A. B. Wilson, Pittsburgh, Pa., writes as follows:

"I have invented a new loud talking telephone receiver which I am sure will revolutionize the present telephone receiver. My telephone receiver has several new points not found in any other receiver and, being cheaper to manufacture and talking very much louder than the ordinary one, I think that my invention is quite important and this is what I would like to know:

"I have heard that some patent attorneys have appropriated inventions themselves or otherwise have given out information obtained from their clients to the detriment of the original inventor. Therefore I do not feel like trusting an unknown patent attorney and would like to have your advice just what to do."

(A.) This is one of the fears uppermost in the minds of most inexperienced inventors and we might say that it is a very groundless fear. It should be understood that patent attorneys are professional men, the same as your doctor, and while there are cases on record where patent attorneys have appropriated ideas, the total of such cases, as to the number of inventions which actually have been patented, is less than twenty in a million.

From this you can understand that an inventor does not take a great chance bv trusting a patent attorney with his invention. As a rule the latter considers one patent much the same as another, and very few if any bother to think about the commercial possibilities of inventions as a whole. We have not heard of a single case during the last ten years of a patent attorney appropriating any ideas of his client and for this reason we think that you may trust yourself safely to most any reputable attorney.

Arc Light Can Be Patented.

(9) Henry S. Fisher, Jr., Hoboken, N. J., sends in a plan and description of an electric arc light and wishes to know the commercial value of his invention.

(A.) The arc light shown seems to have some novel features and a search through our files has shown that nothing similar has been described or patented to the best of our knowledge. We feel quite sure that a patent can be obtained on this extremely novel invention.

We advise you to send your model and a full description at once to a good patent attorney in order to obtain a patent on the invention if possible.

As to the value of any kind of an invention this department cannot give such information because at best it is only pure guesswork. It is impossible for anyone to foretell what a given invention is worth. We might say $5,000 when an invention of this kind in the open market perhaps might not bring $500. Or if some manufacturer wanted it really bad he might pay quite a good deal more than $5,000. It depends entirely on how much a manufacturer or a corporation requires such a device and how much money they think they can make out of it. For that reason it is quite impossible to give any kind of a figure. At best it would only raise false hopes in the inventor's mind, and this department must therefore refrain from giving an opinion as to the commercial or money value of inventions submitted.

Dynamos to charge storage batteries should produce 2.7 to 3 volts for each cell in series, as the cells give a back E. M. F. of 2.2 to 2.4 volts at full charge.

17 FREE SCHOLARSHIPS
ARE NOW BEING OFFERED
LEARN TELEGRAPHY and WIRELESS FREE
The confused condition of the commercial world has created a vast increase in the use of wire and radio. We believe that students who start now will reap the advantages of great opportunity created by the war.
This contest requires no study or special knowledge; anyone with mind enough to learn telegraphy competes on an even basis. Send us 25c (now) for necessary contest sheets, entry blanks, etc., and our book on "Telegraphy and Wireless as an Occupation." You'll enjoy the entertainment this novel contest affords.
BOSTON SCHOOL OF TELEGRAPHY
18 Boylston St., Boston, Mass.

Sunshine Lamp 300 Candle Power FREE!
To Try In Your Own Home
Turns night into day. Gives better light than gas, electricity or 18 ordinary lamps at one-tenth the cost. For Homes, Stores, Halls, Churches. A child can carry it. Makes its light from common gasoline. No wick. No chimney. Absolutely SAFE.

COSTS 1 CENT A NIGHT
We want one person in each locality to whom we can refer new customers. Take advantage of our SPECIAL FREE TRIAL OFFER. Write today. AGENTS WANTED.
SUNSHINE SAFETY LAMP CO.

Your Hands Can't Earn the Money You Need

You'll have to work for low wages all your life if you depend upon your hands to make your living. To earn more money you've got to learn how to work with your *head*—you must have *special training* for some particular line of work.

And you can get this training without leaving your home or losing an hour from your work—the International Correspondence Schools can bring it to you right in your *own home* during your *spare time*. They can train you for the very job you want—where you can earn more than enough money to meet your needs.

If you want to advance in your present occupation, the I. C. S. can train you for promotion. If your present work is not pleasant, the I. C. S. can qualify you for a good position in the kind of work you like best.

Every month more than 400 I. C. S. students of all ages and occupations voluntarily report getting better jobs and bigger pay as a direct result of I. C. S. training. What these men did *you* can do.

Mark the Coupon—Now

What occupation attracts you most or what position do you want? Mark it and mail the coupon now, and learn how the I. C. S. can help YOU to earn more money.

QUESTION AND ANSWER DEPARTMENT.

(*Continued from page* 168.)

One of the best methods ever devised for the type of plant you speak of is that where the individual exciters are all operated on parallel to a pair of "common buses," all of the alternators then receive their field excitation current from these common exciting bus bars. You will thus see that it is a very simple matter to regulate the alternators by means of their field rheostats, and it is best also to have the exciter dynamos rigidly coupled together in some way if possible, so as to minimize the voltage fluctuations in them which would tend to cause one of them to take more of a load than it should, etc. In a great many modern plants the exciters comprise two D. C. dynamos driven by gears, from a single De Laval steam turbine. These two D. C. generators operate in parallel on a pair of common exciter supply buses.

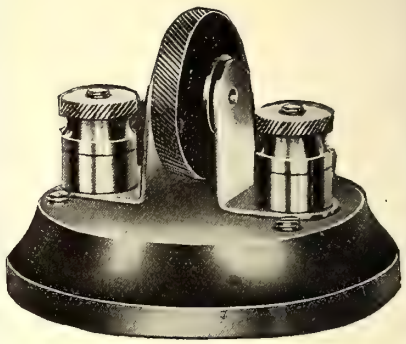
A. 2. In regard to your question on figuring out the resistance and voltage drop in a circuit, etc., would say that if you will think over this matter you will undoubtedly see why both formulas you cite agree. You can prove this by simply taking a voltmeter and connecting same across any given resistance coil, etc., and you will find that the resistance of that particular unit is proportioned to the voltage drop. Therefore that resistance drop as indicated on voltmeter is divided by the current passing through the circuit, as indicated on an ammeter.

Ohm's law also, as you will remember, states that the resistance of a circuit in ohms is equal to the voltage required (or conjointly the voltage drop) to force a given current through the circuit. It is self-evident that the voltage required, in other words, is also the natural *voltage drop*

A. 3. We are not quite certain about your last query regarding calculations of the *average load current* in amperes from the factor of the known load in kilowatts, or whether you mean here the energy put out from the plant in kilowatt hours.

If you mean that the average load as indicated on a direct reading kilowatt meter of the switchboard type was 90 kilowatts during the two hours' run of the plant, then the average current would, of course, be deduced very readily by dividing the 90 kilowatts (or 90,000 watts) by the voltage; which would give you the average amperes load carried during the two hours' run.

BARON MÜNCHHAUSEN'S SCIENTIFIC ADVENTURES.



(*Continued from page* 137.)

stands out in a strong contrast against the inky sky. This pink fringe is not absolutely uniform in thickness; it is thickest near the earth's poles, thinnest near the equator. The difference in thickness is not very great, but quite perceptible. The explanation is that the terrestrial atmosphere, due to the centrifugal force produced by the earth's rapid rotation, tends to throw the air away from the equator. It is therefore forced to move toward the poles and as practically no centrifugal force exists there the air is naturally "thicker" here.

Another curious phenomenon is the position of the earth in the lunar sky. As seen from my present location (near the moon's equator) the earth is almost fixed in the heavens, i. e., it never sets or rises as does the moon when observed from the earth. But otherwise the earth for us goes through the same phases as does the moon for you. Thus during one month the earth

CRYSTALOI

A Permanent Wireless Detector

REDUCES STATIC

IT WILL NOT BURN OUT OR GO DEAD and will last indefinitely. All elements are sealed in the little cylinder which is revolved to secure finest adjustment. The "Crystaloi" is positively the *most sensitive* and thoroughly practical detector ever designed. It is not a make-shift. It is a precision instrument in every sense of the word, and is beautifully finished. WRITE TO-DAY for full information. Immediate delivery.

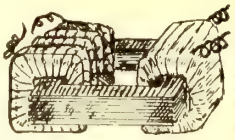
changes from *new earth* to *first quarter,* then *full earth,* then *last quarter,* finally *new earth.* During these major phases we see the earth as a crescent, exactly as you see the moon as a crescent, only the earth crescent we see appears 14 times as large as the moon's crescent appears to you.

During *full earth,* however, we witness a spectacle that is truly wonderful to behold. As the earth rotates on its axis once in 24 hours, and inasmuch as the earth is fixed in the moon's sky, it follows that we must see the earth revolve before our very eyes. Nor do we have to strain our eyes to see the continents; everything is in plain view. As the lighted earth revolves in a black sky the contrast is extreme, impossible to describe. No such scene has ever been beheld from the earth.

The earth revolving from west to east, we see the continents moving from left to right. Thus, when the eastern shores of the American continents are first seen on the extreme left, it takes just three hours till the western shores come in full sight. In three more hours the broad Pacific Ocean and the Hawaiian Islands are directly in front of us, although they can only be seen as dots. Within four hours Japan, then the Philippines and the Australian continent have swung into view, while in four more hours all of Asia is spread before us, with India in the center, like a map. In three hours more eastern Europe, Arabia, as well as Africa, have appeared. Within two hours we see the rest of the European continent and western Africa; then follows Iceland and Greenland and below the Atlantic Ocean. Within five hours from the time western Europe disappeared on the right the eastern shores of the American continents appear once more. Thus we have seen all of the earth in exactly 24 hours—we have been "around" the earth in one day!

The waters of the oceans as seen from the moon appear to be a bluish-green, while the color of the Arctic oceans appears to vary from a pale green to a white. The white color is, of course, produced by the immense snow and ice fields of the Arctic. The color of the continents varies, of course, but the general appearance is a muddy yellow or red. Great plains and forests, as, for instance, those located on the American continents and Siberia show in a darkish green.



Nothing shows up very defined on land. One color merges into the other without showing abrupt breaks. The only lines which stand out tolerably strong are the shore lines, the great inland lakes and the islands. Even these lines do not stand out as strong as one might imagine. The reason for this is found in the earth's atmosphere. As the latter is ever moving, and as we have to look through 35 miles of it—an atmosphere not always clear—it follows that we can never see very sharp lines or markings on the earth.

When I said before that we can see the continents move plainly before our eyes it must, of course, be understood that large tracts are nearly always covered and hidden either by clouds, haze or fogs. Only in very rare instances can an entire continent be seen through its length and breadth, and since I am on the moon I have only seen it occur once, the continent in this instance being the American. Within one hour, however, large clouds had formed over a part of Central America, which became lost to all view within a short time.

With the naked eye, as seen from the moon, it is impossible to discern any object created by man's hands on the surface of the earth. Even large cities such as London and New York cannot be distinguished from the surrounding country. The reason

Here It Is At Last!

This 1/6 K. W. Closed Core Transformer **$6.85**

After months of experimenting, and after making dozens of designs and models we have finally produced a thoroughly practical *closed core wireless transformer* to retail at $6.85, the price that formerly you had to pay for spark coil and batteries.

We have sacrificed nothing in quality or manufacture. The size is smaller—that's all.

This transformer will send messages *twenty* (20) *miles,* with a good aerial, instead of the 2 and 3 miles obtainable on spark coils. Best silicon iron is used in its construction; the best enamel and cotton covered wire; mica insulation; sectionally built.

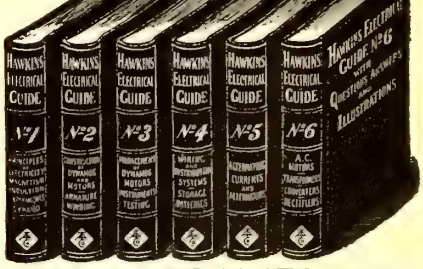
It will throw a heavy, crackling spark that with proper condensers will fill a gap with a ball of fire almost 1-4 in. in diameter.

This heavy spark will send six (6) times as far as 1 in. spark coil.

Send money order today for this new, marvelous little transformer. Shipping weight 10 lbs.

Big Catalog of newest experimental goods, 4 cents in stamps

Write today for our different kind of catalog. New things in wireless and electrical goods. New prices.



THE ELECTRO-SET CO. Dept. C.
1960 EAST 6th ST., CLEVELAND, O.

HAWKINS *LIBRARY OF* ELECTRICITY

In 6 Leather Pocket Books Price per $1 Volume

Here is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of MODERN ELECTRICAL PRACTICE?

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand the "HOW, WHEN AND WHY" OF ELECTRICITY.

"THAT'S JUST WHAT I NEED"

They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. THEY ARE NOT ONLY THE BEST, BUT THE CHEAPEST WORKS PUBLISHED ON ELECTRICITY.

Each book is complete in itself and will be supplied $1.00 per copy, but we believe that the complete set is the best bargain.

The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value.

If you will fill out the following coupon giving all the information requested, WE WILL SUBMIT THE SIX VOLUMES FOR EXAMINATION ON CONDITIONS NAMED

FREE EXAMINATION OFFER

Theo. Audel & Co., 72 5th Ave., New York

Please submit me for examination HAWKINS ELECTRICAL GUIDES (Price $1 each.)

Ship at once, prepaid the 6 numbers; if satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

is obvious, for it must not be forgotten that we look upon the top of the towns—the roofs—and the general color of these does not differ essentially from the streets and the surrounding grounds. For that reason the cities cannot be seen. If all the roofs and the streets were painted in white I am sure that the large towns could be seen, given a clear atmosphere. Thus, you observe, the earth as seen from the moon appears quite lifeless. Nothing is seen moving on it except the clouds; only in one instance have I seen anything out of the ordinary. This was a large forest fire in western America. Even then I could, of course, not see the fire itself, but only the vast, rolling quantities of black smoke were easily discernible. Other objects which can be made out when the weather is very clear on earth are the rivers; but only the larger ones, such as the Mississippi, the Amazon, the Nile, the Volga, etc., can be seen at all. We repeatedly tried to see long railroad tracks stretching across plains, but we have not been successful in locating them, even by the use of our powerful 3-inch telescope. The intervening distance—240,000 miles—is simply too great to see such fine objects. For this reason also some of the greatest achievements of man, such as the Panama and Suez canals, are entirely invisible to us, even with the assistance of our telescope

From the above it must become clear that comparatively small objects such as ships, trains, animals, etc., must forever remain invisible to us *Lunarians*.*

So much for the earth. As I mentioned before the stars appear much brighter on the moon than they do on earth. This again is due to the very thin lunar atmosphere. All the stars appear several times brighter to us than they do to you; furthermore, we can see with our naked eye stars such as are never seen on earth except with the aid of powerful telescopes.

The most inspiring view, however, is the milky way. It shines with a glory undreamed of on earth; its light is so powerful that objects around you become faintly visible in the dead black of our lunar night. The milky way does not appear to be as a weak blur, but it is well defined and we see myriads of stars invisible to the unaided eyes on earth.

There is one thing, however, of importance on the moon of which few people have any conception. I am referring to the meteors which are constantly raining on the surface of the moon. When such a meteor falls on the earth this is what happens:

A great mass of meteoric iron has come under the influence of the earth's attraction and is falling toward it at a speed of several thousand miles a minute. Until it reaches the outskirts of the earth it meets with no resistance, for it moves in the vacuum of universal space. The instant it penetrates the earth's atmosphere an enormous friction is produced between the meteor and the air, and the result is that the meteor becomes wholly or partly melted. Most of it volatilizes and goes up in smoke, to fall down subquently in the form of fine dust; only a comparatively small solid part reaches the earth, where it usually buries itself in the ground. Thus when we see a "shooting star" we see in reality a stream of fire produced by the melting of a meteor.

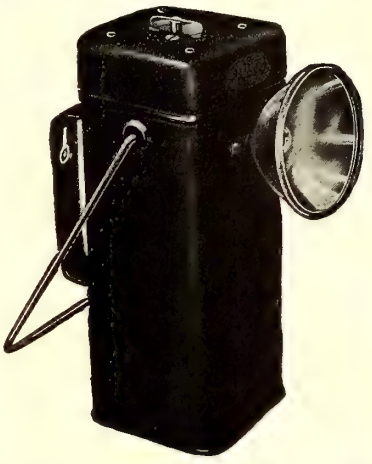
Now, the moon with its pitiful atmosphere affords no such protection as does the earth's atmosphere. Meteors crash about us with an alarming frequency. They come without any warning whatsoever. Some are as large as a watermelon and some as big as a small house. You can hardly imagine what happens when such a heavenly projectile, moving at the frightful speed of from 2,000 *to* 3,000 *miles a minute*, collides with the moon.

The noise of the impact is absolutely overwhelming. The crash of a cannon shot of a 15-inch gun is soft hand-clapping in comparison with it. The ground trembles violently for miles around, and if you are less than 500 yards from the scene one will usually be blown off his feet by the concussion, notwithstanding the very thin lunar air. If the meteor happens to strike a rocky or granite surface the result is even more awe inspiring. As a rule, in that case the whole meteor melts in an instant and goes up in a cloud of white-hot metal vapor. If you are near enough, say within one-half mile, the heat generated by the impact will become unsupportable for a short length of time, and within a few minutes exceedingly fine metallic dust will rain down upon you. It sometimes takes hours for this reddish dust to settle down.

Thus it can be imagined that it is rather dangerous to walk on the moon's surface. This is particularly true in November each year, when the earth and the moon pass through the meteoric "streams." At such a time I would not care to be present on the surface of the moon, and would prefer the lunar caves. Furthermore, I . . ."

Münchhausen did not finish his sentence. There was an abrupt, sharp click in my phones and the ether was ominously quiet once more. For some time I tried frantically to "raise" him, but in vain; he did not reply to me. I became highly alarmed about his safety. Had one of the meteors struck him and killed him? I could not tell. So I finally left my wireless laboratory with an uneasy feeling that everything was not quite right.

(*To be continued.*)



*Term applied to inhabitants of the moon.

TELEVISION OR THE PROJECTION OF PICTURES OVER A WIRE.

(*Continued from page* 132.)

tight structure, made up of a very large number of extremely small metallic cubes, which are all carefully insulated from one another, but, however, presenting a smooth, clean (metallic) surface to the cathode ray discharge on the one side and in contact with a suitable gas, as, for instance, sodium vapor, on the other. It is proposed to construct these screen "cubes" of some metal, like rubidium, which readily discharges negative electricity under the action of a ray of light, the negative charge being imparted to the cubes whenever the thin, pencil-like beam of the cathodic ray falls upon it. The receptacle "K" in the tube chamber is filled with some gas, such as sodium vapor, for the reason that such a gas conducts negative electricity far more readily under the influence of light than in the dark. A metallic screen of gauze, parallel to "J" in the tube is placed at "LL," and through this screen the image of the object at "N" is projected by means of the condensing lens "M," until after passing through the vapor of sodium it is eventually focused on the screen "J." The gauze screen "LL" is electrically connected through a line wire, as seen in Fig. 3, to the metallic diaphragm plate "O" in the receiver tube "A1."

Referring now to the receiving instrument, as indicated in our illustrations at Figs. 1 and 3, there is placed at the end of the Crooke's vacuum tube a fluorescent screen "H," and upon this screen, under certain conditions, which will be explained directly, the cathodic rays impinge, and certain parts of this screen are searched out every tenth of a second by the thin ray, under the combined action of the two A. C.

electro-magnets "D'" and "E¹," which are placed similarly to the A. C. electro-magnets "D" and "E" at the transmitter station. As will be observed, the magnet coils "D" and "D'" are energized by the same A. C. dynamo "F" and also the A. C. magnet coils "E" and "E'" are excited by the alternator "G." It is therefore evident that the two magnetic-control circuits "D" and "D'" and "E" and "E'" and their resultants are therefore in perfect synchronism, i. e., their actions take place at the same time.

A Crooke's vacuum tube "A'" is used also at the receiving station as indicated, and its cathode electrode appears at "B¹." The disk of this electrode, which shoots forth the cathodic ray, is slightly inclined so as to project the ray at a downward angle, through the small opening "a'" in the anode electrode disk "C." Thus, under normal conditions, the cathode rays pass through opening "a¹," but they would be stopped by the diaphragm "P" and its centrally located orifice "S." They, in this case, are not brought under the deflecting action of the A. C. electro-magnets "D'" and "E'" and thus do not reach the image screen "H" before the observer at all. At "O" is a metallic circular disk, which is electrically connected with the screens "LL" at the *transmitter* instrument. Under ordinary conditions the cathode rays at the receiver cannot pass beyond the diaphragm "PS," but they can be made to do so, if slightly repelled by the lower diaphragm plate at "O." In this case, they will then fall on the screen "H" and cause *that part* on which they fall *to fluoresce* (i.e., light up).

Now assume that a uniform beam of cathode rays passes at marvelous velocity and without any appreciable inertia or mass in the tubes "A" and "A'" and that also the A. C. electro-magnets "D" and "E," "D'" and "E'" are energized, as previously explained. Also, suppose that the image of a person, for instance, appears at "N" before the tube "X"; this image is focused and projected through the lens "M," and through the gauze screen "LL" on to the back of the metallic screen "J," which, as will be remembered, is made up of a very large number of small metallic cubes. Then as the cathode rays in "A" oscillate under the combined action of the A. C. electro-magnets "D" and "E" they will cause a negative charge of electricity to be imparted in turn to all the metallic cubes, of which the screen "J" is composed. In the case of the shadows of the projected image, or considering those cubes on the screen on which no light falls, nothing will happen in the action of the apparatus, the charge dissipating itself in the tube. Therefore, in the case of those cubes on the screen which are brightly illuminated by the bright parts of the projected image, the negative electrical charge imparted to those cubes by the cathode rays will pass along, owing to the action of the sodium vapor, which is ionized under such circumstances, and so on until it reaches the gauze screen "LL," whence the charge will travel by the line wire to electrode "O" in the tube "A'" at the receiving instrument.

The plate at "O" will therefore become charged and will slightly repel the rays in the tube, with a result that they will thus be enabled to pass through the aperture at "S" and strike, for a fraction of a second, upon a minute portion of the screen, corresponding in position to the small cube surface on screen "J." This is possible, owing to the fact that the electro-magnets "D'" and "E'" are working in perfect synchonism or step, electrically, with the magnet coils "D" and "E" at the transmitter.

It will be understood, of course, from this description that this action will take place successively, but *not* simultaneously. In

ACCEPT THIS BOOK FREE

IT'S INVALUABLE YET CAN'T BE BOUGHT

Just as you will receive it, cloth bound, size 7 x 10¼ ins., 160 pages, 20 lessons, 350 illus., 30 tables, with every bit of information on Wireless you can possibly want, besides valuable information on Electricity, Magnetism and Theory of them **—and it's FREE as explained.**

Will you take a 20 lesson Wireless Course absolutely FREE—even postage charge prepaid?

A course that tells you everything you can possibly want to know about "Wireless" starting off in Lesson No. 1 by explaining the Principles of Electricity. The Second and Third Lessons are devoted to magnetism, motors; generators and wiring. And then, by simple easy stages this wonderful Course takes you into "Wireless." The mysteries of "Wireless" are unfolded to you by the use of such simple language so skillfully used, that of necessity you must understand every word. The subject is not treated superficially, however, for there is a whole lesson devoted to the Theory and Mathematics of this epoch marking subject. To lend charm to the Course, the last Lesson (No. 20) is devoted to a history of Wireless and the men who developed it. The wireless course positively cannot be bought, but will be sent absolutely free with a full year's subscription (12 numbers) of the Electrical Experimenter at $1.00. It's the biggest dollar's worth you can ever buy anywhere at any time. Send for it to-day enclosing $1.00. Send **now** before you forget.

The coupon below is a convenient way. **But do it now.**

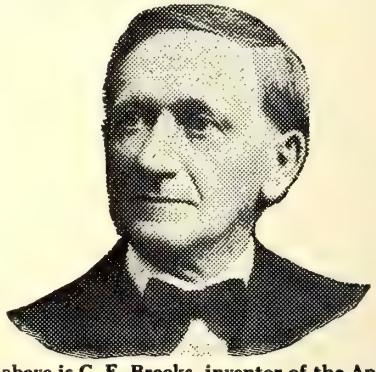
other words, referring back to our previous discussion of how a picture can be built up out of black dots, etc., it is easily perceivable how this device could produce a picture if the illuminated spots on the screen are successively shown in a sufficiently rapid manner. In the case of our little metallic cube surfaces at "J," that are illuminated successively, there appear bright spots at simultaneous periods on screen "H" at the receiving instrument. These bright spots at "H" are of course to appear so quickly, and succeed one another so rapidly and smoothly, that the appearance they present to the eye will be one continuous picture.

It is quite conceivable that the apparatus of the future, which will enable us to see the party at the opposite end of a telephone line, for instance, may indeed work on this principle or a modified one. There is no other method which can work so rapidly and with so little inertia as this one utilizing the Crooke's tube, in which a cathode ray is caused to rapidly oscillate or be deflected through various angles in the same way as the Braun oscillograph tube is used for depicting radio-frequency wave forms. It was the Braun vacuum tube oscillograph that suggested the idea to Mr. Campbell-Swinton for this really ingenious *proposed method of perfecting a Television apparatus.* This is undoubtedly one of the most interesting fields for research work open to the experimenter of to-day.

NAVY TAKES OVER SAYVILLE RADIO



In the interests of American neutrality and to avoid contravention of the Hague Convention forbidding the establishment of belligerent wireless stations on neutral soil during a war, the United States Government refused to grant a license to the Atlantic Communication Company for the operation of the great German wireless station at Sayville, L. I., and took over the operation, management and control on July 9 last.

The Atlantic Communication Company claims to have committed no improper or unneutral act. Further it says: "No charge of any such act has been brought to the attention of its officers by any official of the United States. The Government censors on duty at the station have carefully supervised all messages sent, and have retained copies of the same. The company, being a public service corporation, had no discretion in refusing or accepting messages. As a matter of fact, the station, on account of static conditions, and also on account of lack of power, was unable during the summer months to communicate with Germany for more than one or two hours during the night. This difficulty will now be overcome by the operation of the new transmitter. Communication has been possible for the past few months only when it was night in Germany and night in the United States, which has been, as heretofore stated, only for one or two hours each night."

"And I want to add," Mr. Metz, president of the company, continued, "that as a result of the Federal action to-day we will be able to communicate with Berlin all the time, day and night, instead of an hour or two each day, as has been the case up to the present time. We will now for the first time be able to use the new plant, which is three times more powerful than the old plant, and that plant will be ready the 15th of this month. And, furthermore, there will be a reduction in rates. Instead of $1 a word plus the land rate the rate to Berlin will be 50 cents per word plus the land toll, while messages for Austria and Turkey will be 58 cents per word plus the land charges instead of $1.08 per word as is now the case.

Brooklyn, N. Y., April 15, 1915.

Gentlemen:—The results obtained from my advertisement in the "Electrical Experimenter" really surprised me; in fact the demand for a certain instrument of mine exceeds the capacity for manufacturing and it is all through the "E. E." To date, 79 inquiries, 12 orders. Might state last week filled a $50.00 order netting me a profit of $18.75. As to the exact value of my orders to date, I prefer not to give figures; however, you will always see my ad, month in and month out. I can truthfully say that the "E. E." has it on them all, viz., for quick results, interesting reading matter, etc. Very truly yours. HARRY Y. HIGGS.

FOREIGN Stamps Free, 52 different foreign, including China and Venezuela, to all who apply for our high grade approval selections. Send two cent stamp for return postage. Edgewood Stamp Co., Dept. H, Milford, Conn.

WIRELESS

EXCEPTIONAL Radio Apparatus. A 2c. stamp will bring my literature. H. Y. Higgs, 30 Irving Pl., Brooklyn, N. Y.

WIRELESS receiving set and other instruments for sale. Howard Sorey, Newkirk, Okla.

TUNER—A fine bare wound double Slide Tuner for only $1.75, postpaid. It is made of vulcanite and is a dandy instrument. Send a 2c. stamp for my lists. Carl Rhapstock, Plainfield, Wis.

FOR SALE—Hot Wire Ammeters; two readings, Aluminum casing with bracket; complete except dials; guaranteed. L. R. Jewett, 200 Lewis St., Lynn, Mass.

WE make Loose Coupler, 2,500 meter, $5; Tuning Coils, 350 meter, $2. Cliff Mfg. Co., Box 130, Brookfield, Mass.

AUDION Amplifier Hook-up. Marvelous! Uses one Audion only; Wireless Arcs, any size, Poulsen or Collins type; Inductance capacity, Wave length, Chart; Blueprints either one, 20c. H. Winfield Secor, Consulting Engineer, 2040 7th Ave., New York City.

Scientific Exchange Columns

UNDOUBTEDLY you have at the present time some things for which you have no further use. Do you wish to sell these things or exchange them for something, for which you have immediate use? There is no surer and quicker way to do this than by advertising your articles in these columns. The **Very** people, the **Only** people, who could possibly have a use for your things read this journal. More than 30,000 interested people will see your ad. It is furthermore the cheapest advertising medium for you in the country.

The rates are: One cent per word (name and address to be counted) minimum space 3 lines. Count about 7 words to the line. **Remittance must accompany all orders.**

We reserve to ourselves the right to refuse any advertisement which we consider misleading or objectionable. Advertisements for the September issue should reach us not later than August 10th.

The Classified Columns of "The Electrical Experimenter" Bring Positive Results.

FOR SALE—One Colby Tuner. Tunes up to 600 or 4,000 wave meters, for $3.75. Raymond Clapp, Groton, New York.

EXCHANGE—An Omnigraph and books on telegraphy and electricity for disc phonograph. J. M. Keating, 8 West Center St., Beacon, N. Y.

August Bargains

OUR NEW BIG 216 PP. ELECTRICAL AND WIRELESS CATALOG IS THE EXPERIMENTER'S REFERENCE BOOK

THE BEST BARGAIN IN THIS MAGAZINE IS

No. 7729.

THE AMCO NAVY TYPE RECEIVING TRANSFORMER

Represents the latest advances made towards the ideal tuner and embodies the greatest degree of perfection yet obtained. No greater value can be secured where accurate selectivity, sensitiveness and finish are desirable. The illustration shown herewith cannot possibly do justice to the instrument itself. The primary winding is enclosed in a cabinet, the sides and top of which are polished hard rubber. Two 15-point switches are mounted on the front. One switch controls the primary in groups of several turns and the other controls one turn at a time. The entire variation of the primary is thus secured by the rotary motion of two knurled knobs rather than the movement of a slider, and may be varied from **1 to 225 turns in steps of one turn at a time.** The windings are especially adapted to long wave lengths. The secondary is wound with green silk covered wire. The ends are HARD RUBBER, turned and polished. Secondary variation is secured by a 12-point switch which makes it possible to secure a very fine adjustment.

Uncle Sam and the Inventor

AT last the American inventor is coming into his own. Our Government, which heretofore has paid but scant attention to the activities of our inventors and experimenters, is beginning to recognize that there are a few persons outside of the Department who know a thing or two.

The courageous action of Secretary of War Daniels in organizing a board composed of the foremost American inventors cannot be lauded too highly. Mr. Edison has already accepted enthusiastically Mr. Daniels' invitation as chairman of the new Advisory Board, and no doubt we will soon witness valuable additions in the persons of famous inventors like Orville Wright, Henry Ford, John Hays Hammond, Jr., Tesla, Bell, Steinmetz and others.

This board of famous civilian experimenters will be known as the *Naval Advisory Board* and will have the sole purpose of strengthening our weak national defenses by means of new inventions. The European war has amply shown that battles are no longer won by means of men and guns alone. Never before have scientists won as many battles as now; never before have battles been so deadly as now, due entirely to science let loose on the enemy. As Secretary Daniels states:

"One chemist, one electrician might be greater in the warfare of the future than Napoleon, at his best, was in the warfare of the past. One scientist very probably may do more for the United States than any admiral or general could do."

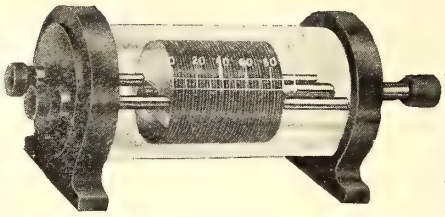
Frightful? Of course. What otherwise can be expected of poisonous gases, electrically charged wires, land and sea mines, bomb-throwing aeroplanes, murderous submarines, and poisonous shells? But then, all warfare is frightful. Once you have been killed, it does not matter whether the ancient sword of a Roman pierced your heart or a modern poisonous gas snuffed out your life. The sole business of war is to kill, and the more frightful and the more terrible our scientists can make war, the better for us.

For it must not be forgotten that, once we arrive at a stage where we are able to annihilate a whole regiment at one stroke, there will be no more wars. People will then think for a long time before engaging in foolish wars, and once people begin to coolly consider, the danger of war is well nigh passed.

As a democratic nation we do not believe in a big standing army, indeed the more the world advances in scientific warfare, the less men do we need to defend a given line. Already the common soldier with his rifle is an anachronism. His rifle is of but little use to him to-day and is fast disappearing. Two men behind a machine gun can hold 500 soldiers with rifles at bay with ease, while in trench warfare the rifle becomes an actual hindrance. Future wars will be machines against machines, far more so than to-day, while the common soldier of the present will man the machines. Land battles will be fought so far apart that men will no longer be able to see each other, as is the case in the present naval warfare, where the battling dreadnoughts are actually shelling each other with nothing but their mastheads showing above the horizon.

Undoubtedly many an American inventor has been bitterly disappointed in the past for not having his invention recognized, or else not having the means, financial or otherwise, to try out his idea in actual practise. This the new board will remedy. The poorest inventor with a good idea will now have his chance to submit it to a board of men who are not to be influenced in the slightest by financial or other considerations. He will get frank and expert advice, which he probably could not obtain anywhere else in the world—and the advice will not cost him a single penny. If his idea is good, he will be told so. If it is not good, he will know that he is on the wrong track, for the men that tell him so are not theorizers, but practical inventors and experimenters, whose opinions can safely be relied upon in all cases.

It behooves us to applaud Secretary Daniels for his momentous innovation and we furthermore sincerely hope that American genius will succeed in making wars so terribly frightful and so deadly that there will not be a "next war."



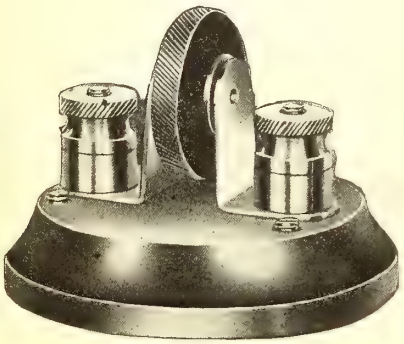
H. GERNSBACK.

NOW WE HAVE

THE NEW TURNEY VARIABLE CONDENSER

This New Condenser Will Add Wonderfully to Your Receiving Range

THE New Turney Variable Condenser meets all the requirements of the most exacting wireless man inasmuch as it has more capacity for its size than any condenser ever made. The great advantage lies in the fact that it is provided with round plates of a special alloy 1½in. in diameter, of which the entire area is available for condensing purposes. This you will find in no other variable condenser.



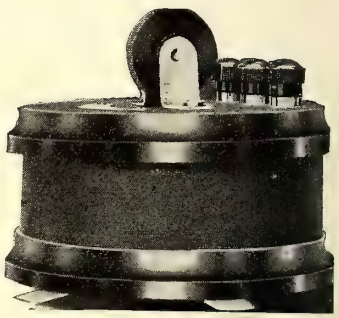
DIMENSIONS 5⅛ x 2½". Made in two capacities.
Type X—35 Plates, price $3.50
" XX—50 " " 5.00

ORDER ONE NOW
and see what you have been missing.

THE New Turney Variable Condenser possesses an absolute zero. This you will find in no other type of condenser. The plates are inclosed in a flint glass tube on which the scale is engraved. It is air and dust proof and can not get out of order. The dielectric is air, therefore the efficiency is the greatest possible. The ends are of hard rubber composition and are highly finished. A handsomer and more valuable wireless instrument you never saw.

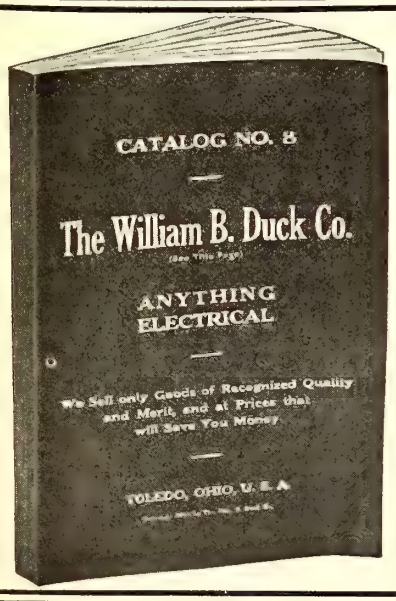
CRYSTALOI TYPE O
Very Sensitive

Price $3.50
Mailing Weight One Pound



CRYSTALOI

A PERMANANT WIRELESS DETECTOR THAT HAS MADE A WONDERFUL RECORD



YOU will find wireless men on land and sea using Crystaloi Detectors in preference to any other detector made. They will not burn out or go dead and are ever ready to pick up the minutest currents that are in the air. They are sold under the Turney guarantee and are making their wonderful reputation on real merit. Send today for full description.

The Wonders of Radium

RADIUM! A thousand years hence a benevolent smile will pass over the features of the average planet inhabitant when he thinks back upon the time when science was still grappling with the mysteries of Radium, the wondrous. It will no doubt seem strange to him how the world could have gotten along for centuries without having subjugated nature's forces to his entire advantage, as he will do then. He will pity us for having lived in a dark age, and his pity for us will be on par with that we now have for the Dark Ages, when man still made the cave his abode.

We are accustomed to think of electricity as being a wonderful power. Indeed, it has revolutionized our lives completely. It might be said that up to the 19th century, that is, before the advent of electricity, man was still uncivilized. We might even go so far as saying that the new civilization period dates back to the year 1791, when Galvani first made his memorable experiment with the frog, incidentally discovering "Galvanic" electricity.

But the wonders of electricity, as we are accustomed to them to-day, are naught when we contemplate the marvels that lay before us when man will finally understand atomic forces. Every particle of matter has concealed within itself undreamt of forces which at present are locked up and are inaccessible to man. Once we are enabled to unlock these forces, the proverbial "Aladdin's Lamp" will grow pale by comparison.

Is Radium the key that will open the door to the Promised Land? What is Radium? What are its functions? Wherein does it differ from a piece of stone? The average man does not seem to know; indeed, it is amazing to find how much ignorance there is displayed at this minute as to what Radium really is and does. The layman has the most astonishing conception about this wonderful element, and the wildest prophecies and guesses are made by people who have a good general knowledge of everyday science.

The purpose of this article is to set forth in a popular manner the wonders and the astounding possibilities of Radium in a non-technical manner as far as that is possible.

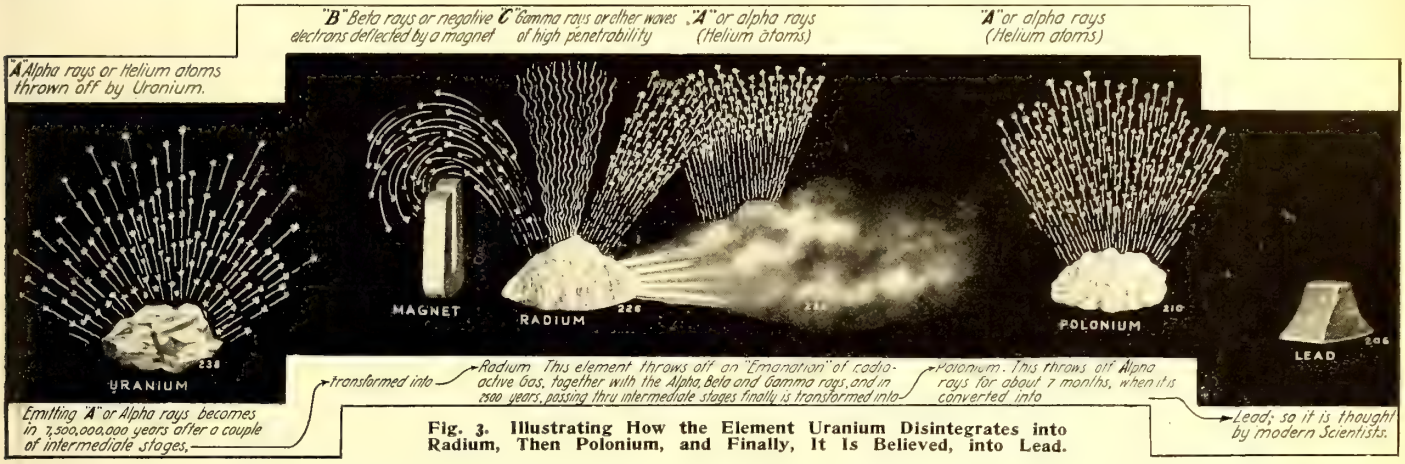

Fig. 3. Illustrating How the Element Uranium Disintegrates into Radium, Then Polonium, and Finally, It Is Believed, into Lead.

IN this prosaic age we are prone to scoff at miracles; we only think of them as the foolish misconceptions of a bygone age. But the most impossible miracles of the past pale into insignificance alongside of Radium, the miraculous. Who could have predicted 20 years ago that 1/50 gram of a new element—Radium—could supply sufficient energy to lift the Woolworth building bodily into the air? Where is the bold prophet who can predict the still greater miracles in store for man? Radium is the key that will open the door to man's final emancipation. This article explains its wonders in a non-technical manner.

History of Radium.

Prof. Henri Becquerel, the famous French physicist, in 1896, while experimenting with the then newly discovered X-rays, wondered if it were not possible to procure a substance that would give off rays similar to X-rays. After numerous and painstaking experiments, he found that his surmise was correct, and he found that the element Uranium was indeed capable of giving forth rays similar to X-rays, without in any way being under the influence or connected to any electrical or other source of power. In other words, he found that Uranium gave off a spontaneous and continuous stream of rays, without seemingly disintegrating while it was doing so. A homely comparison will not be amiss here.

Suppose we have an automobile tire well compressed with air. It would be reasoned that in case of a minute puncture the air

THE ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is $1.00 a year in U. S. and possessions. Canada and foreign countries, $1.50 a year. U. S. coin as well as U. S. stamps accepted (no foreign coins or stamps). Single copies, 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of THE EXPERIMENTER PUBLISHING CO., INC. If you change your address notify us promptly, in order that copies are not miscarried or lost. ***A green wrapper indicates expirati n.***

All communications and contributions to this journal should be addressed to: Editor, THE ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York. Unaccepted contributions cannot be returned unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

THE ELECTRICAL EXPERIMENTER. Monthly. Entered as second-class matter at the New York Post Office, March 1, 1915, under Act of Congress of March 3, 1879. Title registered U. S. Patent Office. will leak out quickly, the tire becoming flat, after the accumulated air has left it. This is a comparison of the X-ray, i. e., the X-ray tube gives forth X-rays only as long as it is connected to an electric transformer. Now, Uranium acts like a tire that has a puncture, but notwithstanding this it does not become "empty." Of course Uranium, the same as any other natural force, will "give out" finally, but it has been calculated that it will take some 7,500,000,000 years before it ceases to be "active."

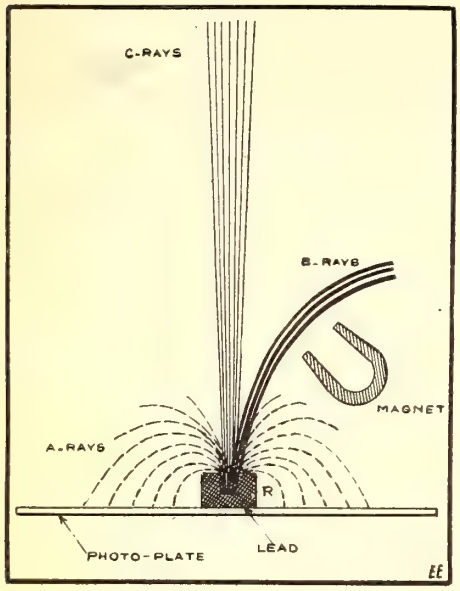

Fig. 1. Showing Effect of Magnet on the "Alpha" and "Beta" Rays.

After Prof. Becquerel had published his reports on Uranium, M. and Mme. Curie, of France, began their wonderful researches independently from Becquerel, and in the course of their tremendous labors discovered Radium and then Polonium.

So far, the element Radium, which we believe to be a metal, has not been isolated in its metallic form. At present we only know Radium Chloride and Radium bromide. We have already, however, ascertained the atomic weight of Radium, which we know to be 236, while Uranium has an atomic weight of 238, while the metal closest related to Radium, namely, lead, has an atomic weight of 206.

Wonderful Properties of Radium.

Let us first enumerate the properties of Radium and wherein it differs from other substances.

If we take a piece of lead, the only remarkable physical properties which we can discover about it is that it is very heavy and that it melts rather easily. If we view it in the dark, nothing can be seen. If we place it on a photographic plate, nothing happens. If we bring it near an electroscope—an instrument which records electrical charges in its neighborhood—the result will be negative.

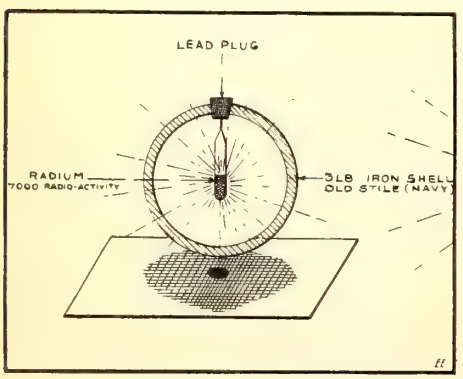

Fig. 4. Lead is Opaque to Radium Rays. The Lead Plug in an Iron Cannon Ball Shows a Black Spot on Photograph as Perceived.

Not so with Radium. If we take a small quantity of Radium salt and place it in a dark room, we will see that it emits a faint glow of light. Place a speck of Radium in front of a fluoroscope, such as is used in X-Ray work, and the screen of the fluoroscope will light up brilliantly, showing the rays to be of a similar nature to that of X-rays.

Indeed, we can prove this by putting our hand on the back of a fluoroscope, placing the Radium behind the hand; if we have a sufficient quantity of Radium, the bones of the hand will be seen clearly outlined on the fluoroscope screen, the same as if X-rays were used.

If we place a speck of Radium on a photographic plate, although the latter is wrapped up in several layers of paper and is placed in a wooden box, the rays of Radium will pass through the box and the paper, blackening the photographic plate.

If we bring Radium near an electroscope, an electrical charge is indicated by the latter immediately, showing that Radium gives off an electrical force.

Radium also gives off what is technically termed as "emanations." Inasmuch as this is a misunderstood term by the average layman, a homely analogy will not be amiss again.

The word "emanation" really means giving off particles of force and matter. The analogy in this case being a garden hose, to the end of which is attached a spraying nozzle. As is well known, the water comes out of this nozzle in very finely divided streams. We can compare Radium to this spray, the emanation being the water as it leaves the spray. But here the analogy ends, as will be seen later.

Radium gives off a number of rays which are invisible to the unaided eye, these rays being termed "emanation," as explained before.

There are three different and distinct types of rays which are known to scientists, respectively, as:

1° Alpha Rays.
2° Beta Rays.
3° Gamma Rays.

The Alpha rays possess certain characteristics of the well-known X-ray, and many have thought these rays to be identical with X-rays, but they do not have any appreciable penetrative power. In fact, they are stopped by a thin layer of air and a piece of paper. They carry with them a positive charge of electricity.

The Beta rays have a much greater penetrative power than the Alpha rays, and the velocity of these rays approaches that of light iself, which is 185,000 miles per second. These rays may be deflected from their original direction by means of a magnet, proving their electrical character. Fig. 1 illustrates this very readily. If we take a piece of lead and bore a small cavity in same, as shown in illustration, and then place a speck or Radium in its cavity, we find that the Alpha rays only make an impression on the photographic plate, as shown. The Beta rays also give off an electrical charge, but unlike the Alpha rays, it is negative, while the former is positive.

The third rays, that is the Gamma rays, possess the greatest penetrative effect of the three. These most powerful rays produce radio-activity through the air for a considerable distance, but they appear not to carry any electrical charge with them, for the reason that they are not influenced by a powerful magnet. That the Alpha and Beta rays carry an electrical charge, or, in other words, give off electricity continuously, is best proven by the following experiment. Refer to Fig. 2.

If we take a gold leaf or aluminum leaf electroscope, as shown at A, and charge it by means of an electrified rod of hard rubber, the two leaves will diverge, as seen. But as soon as any substance containing Radium or pure Radium salts is brought near the electroscope, as shown at B, the leaves will collapse. This action is due to the fact that the rays charge the leaves with opposite electricity, thereby causing them to collapse, again proving Radium to be a body that gives off an electrical charge.

The wonder about Radium, however, is not that it emits these rays and electrical charges, but the mystery so far unsolved is *that it does so continuously and almost indefinitely,* contrary to any other known element so far discovered. In our analogy before we spoke of an automobile tire, if punctured, that never became empty. Exactly so with Radium. It gives off energy without any apparent loss of weight or power or intensity, and while this process seems to go on indefinitely, this really is not the case.

The most remarkable property of Radium, however, is found in its ability to give out a considerable amount of heat without cessation; thus, if a thermometer is placed in a tube containing Radium or Radium salts, and if the thermometer is sealed air-tight to the tube, it will be found that this thermometer always registers a 2.7 degree Fahrenheit higher temperature than the surrounding air.

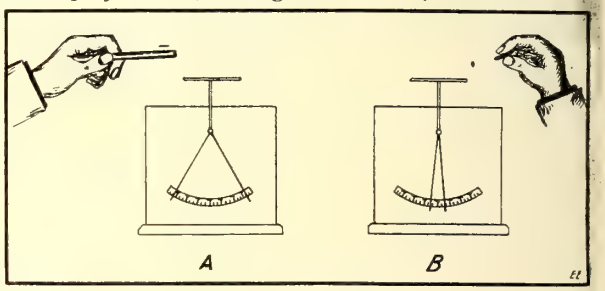

Fig. 2. Demonstrating How if Radium Is Brought Near a Charged Electroscope (A) That It Will Be Discharged (B) Owing to Electronic Rays Shot Off by the Radium.

How immense the energy produced by Radium is may be better understood from the following: *One ounce of Radium will raise one ounce of water from freezing point to boiling point in one hour. And heat continues to be produced at this rate, not for one hour, not for one day, not for one year, but for* 2,500 *years,* before the Radium finally gives out! The greater part of this ponderous energy is produced by the energy of the Alpha particles of the Radium emanation.

A thimbleful of this emanation would contain about seven million calories of heat, sufficient to raise 15,000 pounds of water 1 degree! Weight for weight, the heat evolved by the Radium emanation is nearly one million times greater than that let loose by any known chemical reaction.

Life of Radium.

Prof. Rutherford, who probably to-day is the greatest authority on Radium, has calculated the average life of Radium to be within the limit of twenty-five hundred years. In other words, a given quantity of Radium will furnish energy for twenty-five hundred years without stopping. It is this property which makes Radium so wonderful and so unlike any other substance and element we know. Before Radium was as well understood as it is to-day, it was even thought that we had here an approach to perpetual motion, but we have since learned

that this is not the case. But it is truly remarkable that any substance should be able to give forth such a tremendous power for

Fig. 5. Radium Picture of Mouse. Exposure 24 Hours. Photo Taken by William J. Hammer.

such an exceedingly long time without materially weakening.

However, there is probably something behind this which we have not as yet ascertained. A theory of the writer has long been that Radium is nothing but a form of "sponge" which takes up within itself some unknown to us energy, transforming it into an electrical energy. While this theory has not been proved nor disproved, it opens up a new avenue in research. Undoubtedly, something of this sort must take place, as otherwise Radium would be contrary to almost every rule of the conservation of energy.

Scientists from time immemorable have been trying unsuccessfully to transmute a lower grade metal into one of the higher orders. Thus many of the alchemists have tried to convert lead and other heavy metals into gold, silver and other precious metals, without success. Radium, at last, has given us a means by which this may some day become accomplished. Our Fig. 3 shows graphically how the alchemist's dream has at last come true. Here we see how one element is actually changed into another one. In other words, it shows the transmutation from Uranium to Radium, from Radium to Polonium, and from Polonium finally to Lead. While this has not been conclusively proven so far, the indications are that the sequence as stated above is the correct one, and from this it may be inferred that at some not far distant date it will be possible to change one metal into any other given one.

It is thought by many scientists that Uranium is broken up and disintegrated into Radium, as shown in our Fig. 3, which shows the subjects at which the Alpha rays, Beta rays and Gamma rays are respectively emitted during the break-up, if such really occurs with the so-called Radium atom. While various theories have been brought before the scientific world, none of them has as yet been accepted as final, on account of the different results each observer obtains, and for this reason no final conclusion can be stated here.

As we also stated above, the disintegration of Radium is continuous, and while the average life of Radium has been calculated to be twenty-five hundred years, this, however, is not final and is merely hypothetical.

Various Radium Effects.

Prof. Rutherford, who has conducted a most painstaking investigation into the penetrative character of all the radiations of Radium, Uranium and Thorium, has found that lead was the best insulator for the radio-active rays, and for this reason Radium is always kept in lead cases or lead bottles. Fig. 4 shows this very nicely. Some Radium salt is placed in a glass tube, the latter being attached to a lead plug, and the tube is then inserted in a three-pound iron shell, such as have been used in the past by the navy. If this apparatus is now placed upon a photographic plate, the rays will of course pass through the iron shell, but cannot pass through the lead; the rays will now be reflected from the lead plug and will strike down in the axial direction of the tube. When the photographic plate has been developed, it is found that a picture of the lead plug has been photographed on the plate, simply by reflection. In this case the rays not only penetrated the iron shell, but also the rubber cover which enclosed the photographic plate on which the shell rested. A strong black spot in the center of the picture was the result.

An interesting photograph is shown at Fig. 5, which is a Radium (X-ray) picture of a mouse. This mouse was radiographed in about 24 hours by placing it directly on a photographic plate, six inches above which were supported on a cardboard frame six

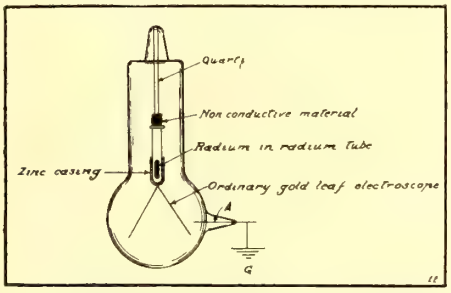

Fig. 7. Radium Will Run This Clock 2,500 Years. The Nearest Approach to Perpetual Motion.

tubes of Radium having the following radio-activities: 40, 100, 250, 1,000, 3,000 and 7,000, as compared with Uranium (the standard). This arrangement was put in the bottom of a trunk, the trays being replaced, and the trunk wrapped in three thick rugs and kept in a dark room. This picture well shows the powerful penetrative power of these wonderful rays.

Fig. 8. Radium Light is Practical, and Actually Permits One to Read 6 Feet Distant From the Bulb.

Besides having all the wonderful properties enumerated above, Radium still has another property, and that is its effect upon man's body. One of the earlier Radium

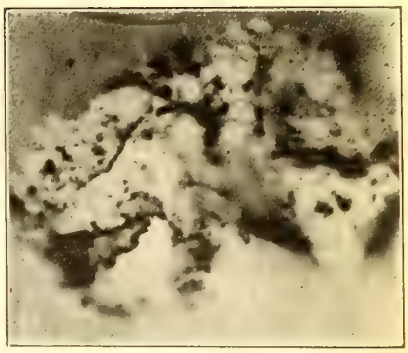

Fig. 6. Auto-Photograph of Piece of Pitchblende Taken by Its Own Rays.

scientists was carrying a glass tube containing Radium salts in his vest pocket. While there were no bad effects to be perceived, and while the Radium did not seem to do any harm when placed upon the naked skin for a short time, bad burns appeared within a few days, which proved to be exceedingly hard to heal, and produced worse effects than the well-known X-ray burns which many persons experimenting with the latter rays experience.

In connection with this, however, a very curious paradox has been discovered by Dr. Robert Abbe. In a lecture on "X-ray Epithelioma Curable by Radium," Dr. Abbe recently delivered a paper to the *Journal of the American Medical Association*. This scientist claims that by using Radium in a certain manner, these X-ray burns can actually be healed by means of Radium. This seems more proof that the properties of the Radium rays are vastly different to those of X-rays.

As said above, Radium is not without its dangers. It is also very dangerous to the eyes, and if Radium is viewed very closely it may result in ultimate blindness, if the experiment is carried on for any great length of time. In connection with this, a curious fact was found in the following:

If a person is taken into an absolutely dark room, and if a small tube containing a Radium salt is placed directly over the closed eye, a strong sensation of light within the ball of the eye is experienced. Some explanations have been offered as to this result, but none is quite satisfactory.

While Radium is no doubt dangerous, if handled by the layman, the medical profession has already made great use of the mysterious element. It seems that cancer and some other diseases have been actually healed by placing a minute quantity of Radium, sealed in a tube, on top of the sore. Some phvsicians have even gone as far as to open cancers and placing a very small tube in the inside of the diseased flesh, and in many cases a permanent cure has been the result. In case of cancer of the stomach the patient has been made to swallow a small glass vial containing a very minute quantity of Radium salt, thereby bringing the latter in close contact to the cancer, and in this case also many cures have resulted.

Of course such experiments must be carried out very carefully, and it is especially the quantity of the Radium salt that is important, for if too much is used disastrous results will be experienced.

Of course, we are but at the beginning, and more wonders and cures are to be expected by the direct application of Radium.

A curious experiment was performed by Mr. William J. Hammer, the well-known experimenter, who several years ago visited the aquarium of Naples, Italy. This aquarium has a large collection of electric fishes, and Mr. Hammer experimented with the *Torpedo Galvani* and the *Gymnotus Electricus*. As is well known, these fishes are capable of dealing a very powerful electric shock, if the bare hand is brought in contact with the body of the fish. The shock, in some cases, has been strong enough to kill a grown man. Mr. Hammer, who had obtained several tubes of Radium from the Curies, of Paris, placed these tubes directly upon the body of the fish. The tubes were left for some 20 minutes in contact with the fish's body, and it was found that the Radium emanations had entirely dissipated the fish's electrical charge and the animal was no longer capable of giving electrical shocks for quite a time.

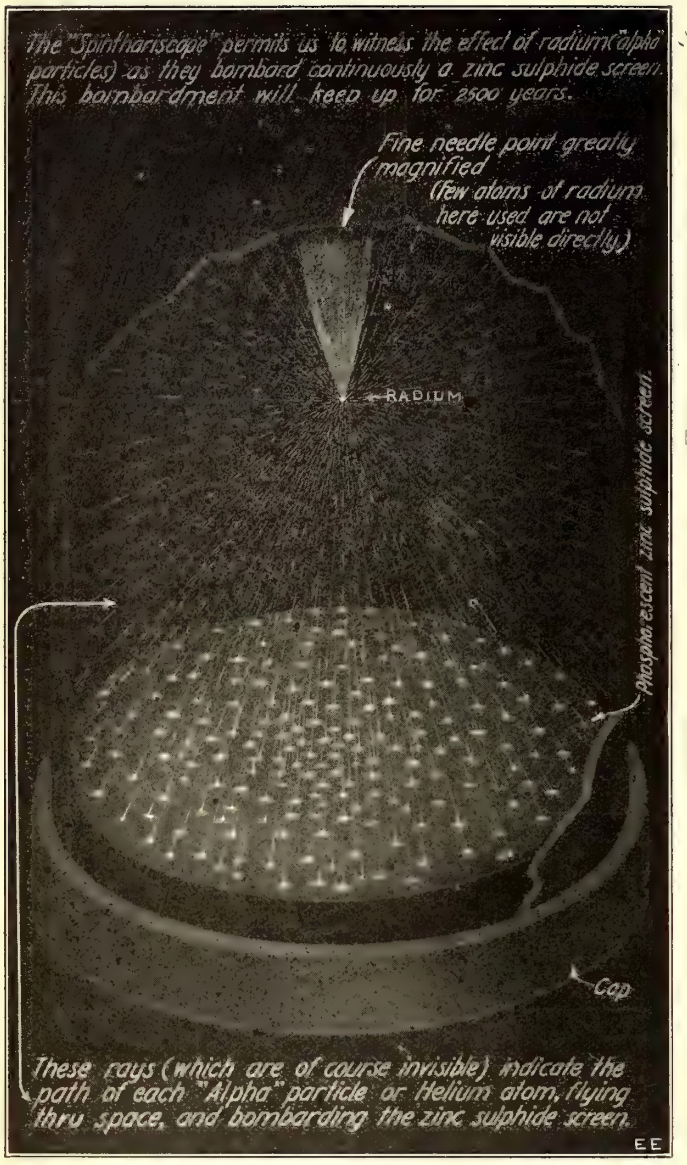

Fig. 11. Magnified Sectional View of Interior of Spinthariscope.

Radium Supply of the World.

There is but very little Radium in the hands of man to-day. By this we mean that only about one pound of Radium or Radium salts is actually in use, for the reason that Radium is one of the most difficult substances that can be obtained. At the present time almost our entire supply is obtained from Austria, from the mineral called "Pitchblende," and this form of pitch is highly charged with various Radium salts. There is only one part of the element Radium for every 3,200,000 parts of the element Uranium in Pitchblende. Of course, the Pitchblende may be of any degree of richness from only a few per cent. to over 50 per cent. of Uranium, but between 100 and 200 tons of even the richest Pitchblende would be required to produce an ounce of pure Radium. The commercial compound, usually called Radium bromide, if pure, contains some 58 per cent. of Radium. It is like the myriad of roses we are told go to make a single drop of attar, which is almost priceless.

The Radium that is extracted is a million times more radio-active than the mineral, and several million times more than Uranium itself. Our Fig. 6 shows the autophotograph of a small piece of Pitchblende, which was placed on a photographic plate in the dark, making its own photograph by means of its own rays. We might also state that Radium itself is not luminous, and this is best proven by the fact that weak Radium preparations shine by themselves more in the dark than the pure Radium salts, owing to a phosphorescent action of the impurities which are to be found in the weaker salts.

Fig. 10. View Through Eye-Piece of Actual Spinthariscope.

Practical Applications of Radium.

We now come to the practical applications of Radium. We have shown in our Fig. 2 how the leaves of an electroscope can be made to converge and diverge, and it is upon this principle that Prof. Strutts has designed what he calls a perpetual clock. This is the nearest approach to a practical perpetual device as yet invented. Our Fig. 7 gives a view of this. It consists of a glass bulb, as depicted, which encloses a gold leaf electroscope, some Radium salts and a wire, which latter is connected to the earth. These parts are arranged as shown, and it works as follows:

The emanation of Radium charges the leaves, which diverge slightly until one of them touches the wire at A. As this terminal is connected to the ground, it carries off the electrical charge from the leaves, leaving them uncharged, and they consequently will collapse. The Radium, however, which gives off a continuous charge of electrons, charges the leaves anew, which open, then discharge, and then charge again. A suitable delicate contact could no doubt be arranged to the leaves, so that it would close a secondary electric circuit operating an electro-magnetic device, which would then operate an electric clock. Or a very sensitive attachment could be placed directly inside of the bulb, which would operate some very light hands playing over a clock dial. With suitable means an accurate Radium clock could thus be constructed, no doubt.

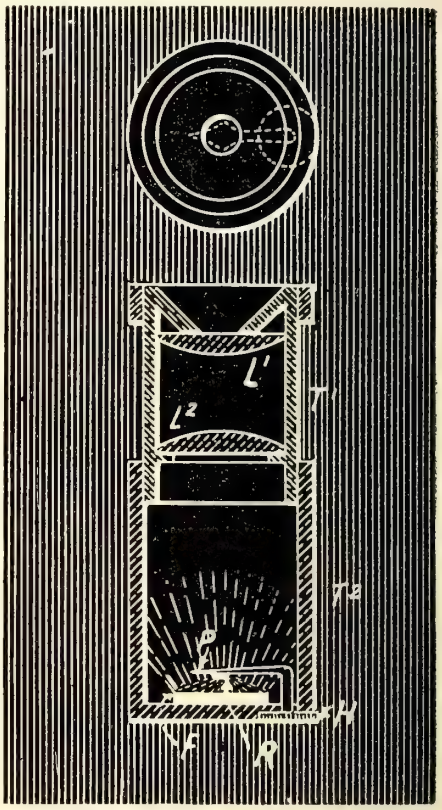

Fig. 9. Details of Spinthariscope Whereby Effects of Radium May be Observed.

We have shown before that Radium is capable of lighting up a fluoroscope screen, and an interesting application is found in producing light through means of this property. In the future it is well possible that buildings and streets may be lighted by means of a similar arrangement as that explained hereafter.

Professor Curie constructed an apparatus as illustrated in Fig. 8. It consists of two large glass bulbs, one having a solution of Radium salts, the other a small quantity of phosphorescent zinc sulphide. The two

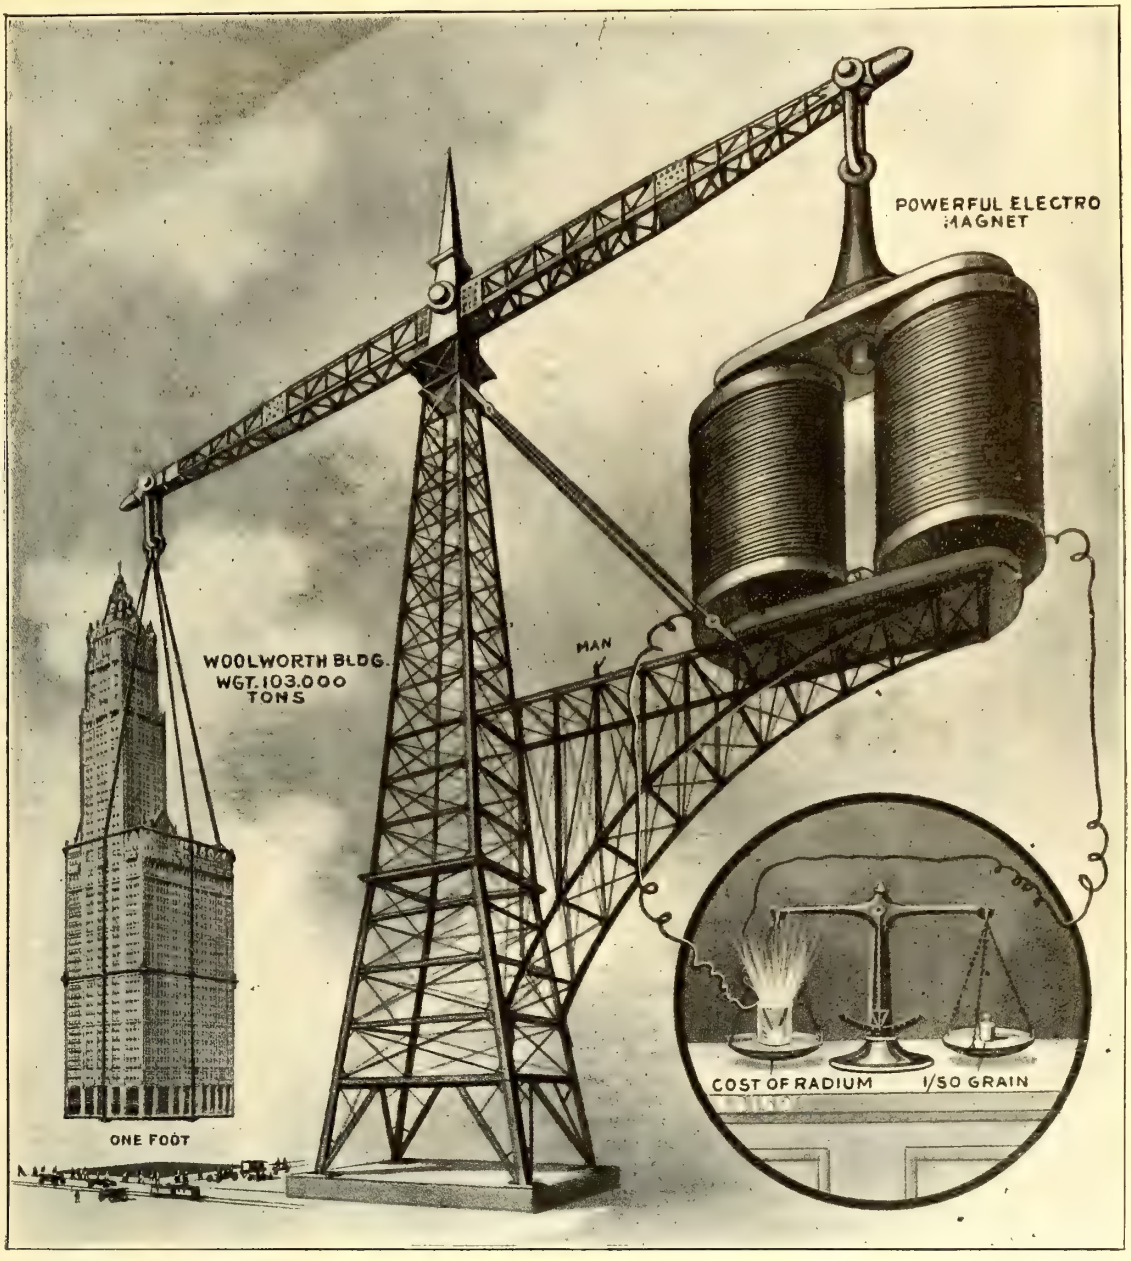

Fig. 14. How (Theoretically Considered) the Energy Contained in 1/50 gram of "Radium" Could Lift the Massive Woolworth Building 1 Foot Above the Ground.

bulbs are connected by means of a glass tube, in the center of which is a stopcock. Upon placing the apparatus in a dark room and opening the stopcock, the Radium emanation will be sent from one bulb through the tube over to the zinc sulphide, and this salt will be immediately illuminated with such an intensity that one is able to read a newspaper six feet away from the bulb, as shown in our illustration. This is so far the nearest approach to cold light as yet invented. As nothing is consumed, such a lamp would, of course, last almost indefinitely.

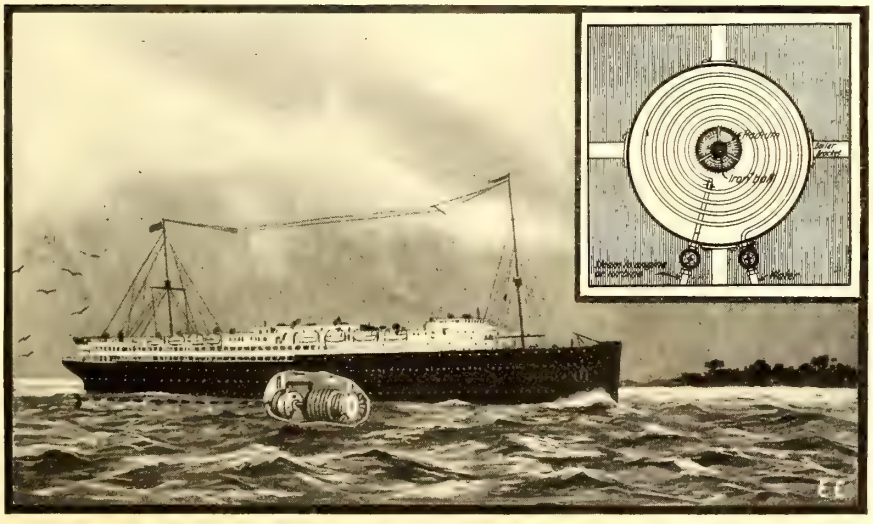

Fig. 12. Modern Ocean Greyhound Being Driven with Radium. Insert, Fig. 13, is Detail of Radium Boiler.

A very clever instrument working on the above principle and termed "Spinthariscope," invented by Sir William Crookes, is illustrated in our Fig. 9. It consists of the following:

There are two brass tubes, T^1 and T^2, the upper sliding into the lower. The upper tube carries two condensing lenses, L^1 and L^2. At the bottom of the lower tube we see a small screen F, covered with phosphorescent zinc sulphide. In front of this is a small pointer P, bearing a small quantity of a Radium salt R. This pointer may be revolved from the outside at H.

Combating the Submarine by Electrical Means

By H. Winfield Secor

THE submarine has already shown its wonderful flexibility in manoeuvering under war conditions and it has kept inventors busy right along, who have endeavored to perfect some means, electrical or otherwise, to detect the presence of such a submerged war vessel even though it be several miles away from its intended prey. A number of different schemes have been proposed and tried out in some instances, but without much success. In the present article some of these schemes will be considered briefly, and they include wireless and other diversified plans and arrangements.

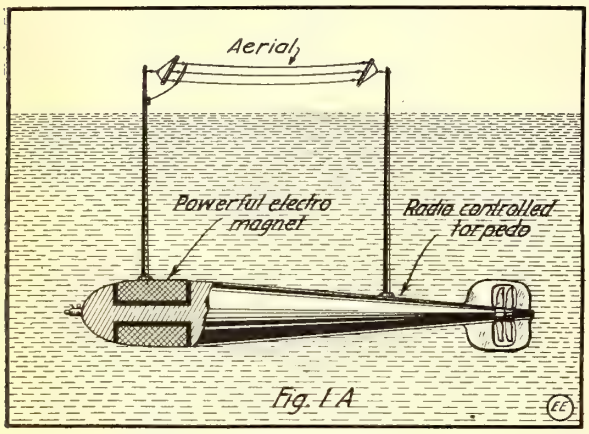

Fig. 1A. Wireless Directed Torpedo Carrying Powerful Magnetic "Head."

One of the latest wireless torpedo schemes has been evolved by a Mr. Gardiner, of Fleetwood, England, and our front cover depicts his scheme in a graphic manner. Simply explained, his arrangement is as follows

An aeroplane, it has been found, can see a submarine when submerged even 150 feet below the surface of the water. It carries a powerful wireless set, and its means of destruction, as regards a submarine cruising under water constitutes a powerful torpedo which propels itself under water and is subject to the wireless control of the man in the aeroplane. The wirelessly controlled torpedo in this case is suspended by proper wires or cables from a non-sinkable float, the latter carrying suitable antennae to pick up the wireless control waves as sent out from the aeroplane flying overhead.

This idea of Mr. Gardiner's has been very favorably received in England, and it is said that it will shortly be tried out by the English Admiralty. This scheme seems to hold good promise, as is evident in view of the known facts in the case, viz., that it is possible for an aeroplane scout to see a submerged submarine boat many feet under the water, and also that there are successful wirelessly controlled torpedoes existing at this time. Therefore, this invention seems indeed practical, and when the aeroplane scout spots a submarine coming along under the water, he sends out a proper wireless control wave, which causes the non-sinkable float and its attached torpedo to proceed directly toward the submarine. Also it is possible to control by wireless waves suitable mechanisms, such as take-up drums, on the torpedo, so as to cause same to rise or descend. Ballast tanks might be thus controlled for the purpose. The explosion of the torpedo could be, firstly, by concussive contact in the usual manner, or, secondly, it could be exploded by wireless means from the aeroplane; and it would not matter whether the torpedo exploded a couple of feet from the submarine or at a considerable distance from it, as the force of the explosion is transmitted through the water to a considerable distance, owing to the (practically) incompressibility of this liquid

We have all heard, probably more or less, about these torpedoes which can thus be controlled by radio waves of different frequency. In this connection a new suggestion is made as outlined at Figs. 1A and 1B, in the form of a radio controlled torpedo, carrying an aerial as observed, and also having its "head" fitted with a powerful electro-magnet. A scheme is suggested by the writer which, though theoretical in a way, might be applied under certain conditions for the protection of a warship, and also for the purpose of searching out a harbor, etc. This scheme would operate on the principle that, to begin with, we have a powerful wireless controlling station, either on board a dreadnaught, or on the harbor shore. Wirelessly controlled torpedoes of the type shown at Fig. 1A are then employed with the strong electro-magnets attached to them as aforementioned.

Referring to Fig 1B, it is seen how four zones (and of course more zones could be provided for) are covered at different times by wirelessly controlled torpedoes, sent out from properly devised and arranged torpedo discharging tubes. It is to be noted that when the radio torpedo A is at the point shown that its mate, say at B, is opposite it, but traveling in a different direction, and that when B has reached the point X the torpedo A will have reached the point X^1. This holds good also for torpedoes C and D. Thus, by sending out these radio controlled torpedoes, which can be directed and made to go in any direction desired, they are caused to search out the water for several miles in the vicinity of the ship. It is proposed that a ship would carry a net, so as to be able to pick up its returning radio torpedo without danger to itself. Tests made about two years ago in the English navy with torpedo nets proved that torpedoes could be picked up very easily by allowing them to strike the net and then picking them up by means of grappling irons.

An electrical scheme (it is said) is being used in several navies for the detection of submarines or other vessels when several miles away, which involves the use of an extremely sensitive microphone submerged under water and pivotally mounted on the side of the war vessel or dreadnaught. This device is illustrated at Fig. 2. By suitably arranging the microphone M so as to be constantly and rapidly rotated about its axis, it is seen to cover a complete circle about the ship, as indicated by the dotted line A and B. By properly constructing the microphone M and a horn on same, it seems possible that this method would allow of detecting the sound of the machinery, and especially the *propeller*, of the enemy's war vessel to within a single degree of the compass. Not only does this method seem undoubtedly feasible, but also, with the several types of amplifiers now available, it is a simple matter to hook up one of these with the circuits of the microphones M and to thereby increase the activity and usefulness of this arrangement. As submarine wireless telegraphic communication is carried on by sound vibrations transmitted through the water up to a number of miles, there is no reason why this scheme should not prove efficacious in every way. Of course, suitable telephone receivers or other indicating means are connected to the microphone circuits.

In this direction of scientific apparatus for the detection of the presence of a hostile warship in the neighborhood of a dreadnaught there is often brought up a more or less logical argument by many, viz., that, having obtained the information aforementioned as to the presence of a submarine, say, then what good is this information after it has been obtained? The answer to this argument would be, it seems, that if those on board the dreadnaught are duly apprised of the fact that a submarine lies within active range of them, then they will take all necessary precautions to ward off any attack by such a vessel. It is evident, of course, that this microphone scheme, for instance, of detecting the presence of a hostile vessel would do its duty, even though the submarine is cruising under water with its periscope out of sight; and if this or a similarly efficient arrangement is not utilized, then it is certainly impossible for those on the dreadnaught, under ordinary conditions, to know of the presence of such a boat.

The dream of a great many inventors in the wireless line, including Ulivi, of Italy, has been to utilize some special form of wireless ray or wave which could be directed toward a submarine or war vessel of any type, and that would cause the powder magazines of same to explode, thereby destroying the hostile vessel.

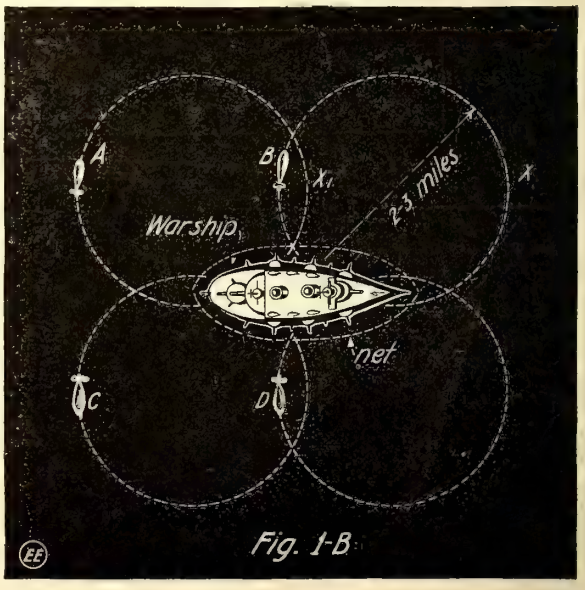

Fig. 1B. Scheme for Protecting "Dreadnaught" from Submarine with Several Radio Directive (Scouting) Torpedoes.

Ulivi's scheme was demonstrated, it is

claimed, before bona fide naval authorities of several foreign governments, but it has since been stated in several instances that the tests were a hoax and, moreover, that he could not produce the effect he claimed to have achieved with the apparatus employed. Several of the best radio authorities and scientists in this country and abroad have since gone on record as stating that it is indeed very doubtful if there ever

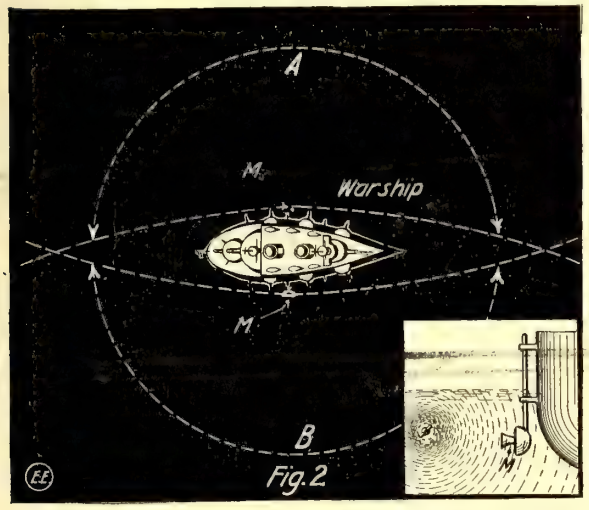

Fig. 2. Super-Sensitive Microphone Picks Up Sound of Submarine's Propeller and Machinery. Note Sound Waves (in Insert) Striking Microphone.

will be such a "wireless ray" perfected which would explode a submarine or the powder magazine in a dreadnaught. This seems, in the writer's opinion, to be the conclusion, reached in any event along this line of research, as in all cases the explosive is encased in metallic shells which are highly impervious to radio waves. Even if such waves do induce (as we know they can) minutely small local currents inside of the metallic shell encasing such explosives, they, as tests have often demonstrated, circulate around the shell and in some rare cases do produce a small spark between two sections of such encased metallic shells where they are not joined together firmly and metallically.

However, and even though this effect is possible, it should be remembered that at a distance of a few miles, even, the energy so produced and localized in a metallic body or shell by wireless waves radiated from a central station is very small. Undoubtedly, from what has been published of Ulivi's work, this effect is what he intended to utilize in his marvelous ray that would blow up all the battleships in the world. If Ulivi had succeeded in his arrangements and apparatus they would undoubtedly have been employed long ago. So there are still good opportunities for some bright genius to bring forth a successful combatant for the modern terror of the seas, "the invisible submarine."

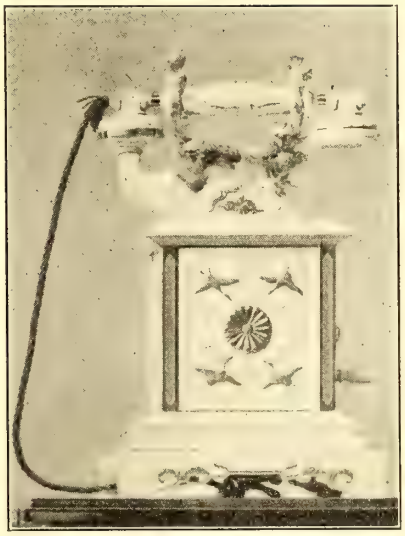
ON CURING ILLS BY ELECTRICITY.

A distinguished European physician, Kowarschik, declares that we are entering on a new era in the field of electrotherapy, as the mechanical technic has been so perfected, while our knowledge of the biologic and therapeutic action of electricity has been deepened in recent years.

The theory of electrons and ions has provided a scientific basis for therapeutic action, a basis more solidly planted, he insists, than we have for the action of most of our drugs. Among the favorable accounts of ion treatment published recently is that of Aufaure with acute and sub-acute articular rheumatism treated by driving a 10 per cent. solution of sodium salicylate directly into the joints with the electric current. The effect was found to be superior to that with internal administration of the drug.

Excellent results in the treatment of chronic nose and ear disease and sinusitis are reported by Friel. A 1 per cent. solution of zinc sulphate, with a current of two or three milliamperes, was used at a 10-minute sitting and repeated at eight of 10-day intervals. Sometimes a single sitting completed the cure.

About half of the cases of sinusitis thus treated were cured and a large proportion of the middle-ear cases. Kowarschik says the eye and ear affections seem to offer a specially favorable field for diathermy, as also malignant growths of all kinds.



RADIO TIME SIGNALS SENT 4,250 MILES.

The wireless signals sent out by the United States Naval Observatory at Washington have been caught as far away as a point 600 miles north of Rio de Janeiro, which is 4,250 miles from the Government station. Watchmakers, jewelers and colleges throughout the country have installed apparatus for catching the signals. In the past year the daily error in transmission ranged from .055 second to .36 second, due to a change of rate in the standard sidereal clock in consequence of overhauling.

The observatory is seeking an appropriation from Congress for more efficient sending apparatus, declaring that the increased use of the signal for astronomical and other purposes requires a higher degree of precision.

ELABORATE JAPANESE TELEPHONE SET.

The illustration here portrays a very beautiful and odd telephone desk set, decorated with ivory, gold and silver, and which cost about $3,500 to build. This set is illustrated by courtesy of the *Western Electric Co.*

Beautiful Telephone Set Presented to Emperor and Empress of Japan.

This very elaborate telephone instrument was presented to the Emperor and Empress of Japan at the time of their marriage. Some of the Japanese telephones are works of art, but in America we are content to have one standard of finish for our telephones, which makes for maximum efficiency as to talking qualities as well as wearing qualities.

RUBBER PRODUCED ARTIFICIALLY BY ELECTRICITY.

By Frank C. Perkins.

Our illustration shows the electrical equipment by means of which a Cleveland doctor believes rubber can be produced artificially, the chief ingredient of the product being coal tar.

Electrical Apparatus with Which It Is Claimed Substitute for Rubber Has Been Made.

Dr. Lyman A. Noble, an electro-therapist, has declared he has discovered a formula by which a substitute combining all the qualities of natural rubber can be produced. For nearly a year Dr. Noble has been experimenting with ingredients and processes for the production of artificial rubber.

In the process he uses a high frequency electric current. In his first experiments he sought to produce rubber by evaporating the liquid combination of ingredients. This did not produce the desired result, and in addition to the evaporation process he conceived the idea of submitting the liquid to the high frequency current for an extended time—six hours—and the result was obtained.

It is stated that from 200,000 to 500,000 volts of electricity of high frequency is necessary to produce the rubber. With a current of 1,000,000 volts the time would be greatly cut down, he states.

The various ingredients are mixed, by secret formula, into a liquid which, under heat, is evaporated down to one-quarter of its original mass. When it has reached a consistency of a thick syrup the mass is placed in a metal retort and connected with a high frequency electrical machine used by Dr. Noble, and the retort forms one pole while the other pole is suspended in the liquid. The current is turned off after six hours; the retort contains a black, spongy substance with all the qualities, it is claimed, of natural rubber. A series of tests show that the product resists both wear and punctures to a greater degree than regular rubber.

NEW LOUD TALKING TELEPHONES USED BY THEATERS.

A NEW form of attraction recently installed by a progressive New York City theater is that involving the use of a loud-talking telephone arrangement. This apparatus is illustrated herewith, and it involves several very unique features.

To begin with, this instrument operates on a 110-volt circuit, and the microphone, of the carbon grain type, as shown at Fig. 1, has a diffusing button placed at the base

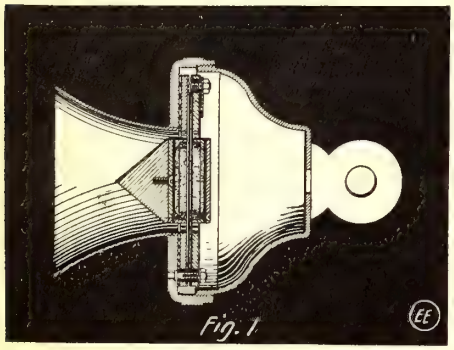


Fig. 1. Special 110 Volt Style Microphone Transmitter for Loud Talking Enunciator.

of the mouthpiece, as perceived. This transmitter is hooked up in series with a couple of 110-volt tungsten lamps of about 50 watts capacity, and it actuates directly the resonator or reproducer, shown at Fig. 2.

The horn on this reproducer is only about

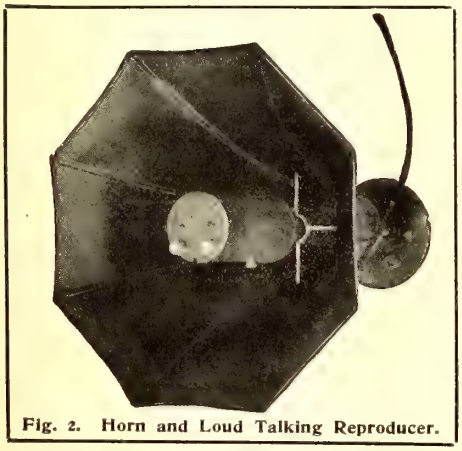

Fig. 2. Horn and Loud Talking Reproducer.

18 inches long, and the appearance of the complete reproducer, with magnet coil, is shown at Fig. 2.

The transmitter is of peculiar construction and especially adapted to stand a heavy current. It employs in its make-up three distinct electrodes, and as it thus has a compartment, containing carbon grains, placed at both sides of the center diaphragm, it is seen that, as compared to the ordinary transmitter, having but one carbon grain chamber, its current carrying capacity is 100 per cent. greater. This microphone has several other distinct constructional features which permit it to be inserted in the 110-volt circuit, and it does not overheat, even when used for half an hour or more at a stretch.

When used to energize from one to five loud talkers or reproducers about ¼ ampere of current is best passed through the microphone.

The special double microphone arrangement, with suitable arm, etc., for use on talking machines where music is to be transmitted through loud talkers, is illustrated at Fig. 3. This specially arranged talking machine is driven by an electric motor, and the switch for operating same may be seen on the side of the cabinet. The two microphones forming the transcribing head in this case are actuated by the regular stylus needle resting on the graphophone record, and suitable wire lead along the microphone arm to and from them.

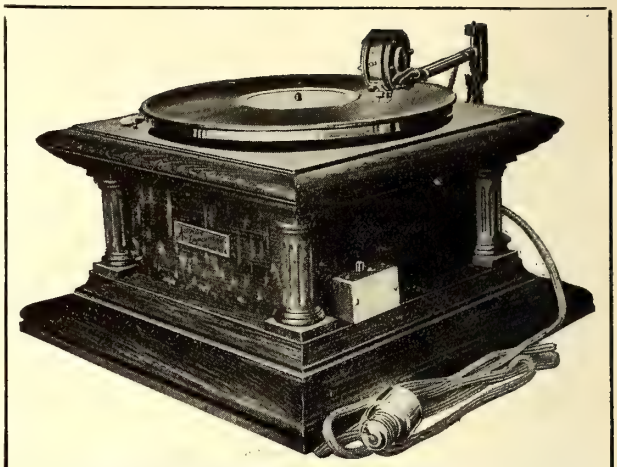

Fig. 3. Special Graphophone and Microphone Arm for Producing Music Through Loud Talkers.

Considerable interest centers in the improved construction of the loud-talking reproducer, shown at Fig. 2. At Fig. 4 the details of the inside mechanism of the reproducer are portrayed. Several years were spent in developing this type of reproducer, which operates on the lever principle. The whole mechanism, shown at Fig. 4, is encased in a tubular metal chamber about 3 inches in diameter by 8 inches long. Large bars of the best grade tungsten steel are used as permanent magnets, and an electro-magnet coil similar to those used in regular telephone receivers or reproducers is mounted on the end of the permanent magnets at A. The iron armature, which is very carefully built, is at one end, directly supported by one pole of the permanent steel magnets, and the other end of the armature is supported and held 2/1000 of an inch from the head of the other pole piece by a mica diaphragm, which is embedded in a rubber cord. A system of levers connects the vibrating end of the armature with the mica diaphragm in such a manner as to cause this diaphragm to have a magnitude of vibration from two to three times as great as the armature. The large volume of sound obtained in this perfected loud-talking reproducer or receiver is due to the powerful magnetic circuit and also to the amplifier vibration effect. The tone quality is due to the mica diaphragm, which has been found much superior to the usual metal form, and also to the manner in which it is mounted in the sound box.

This arrangement is being used for railway station train announcement, restaurant purposes, et cetera, and apparently works better than anything placed on the market heretofore.

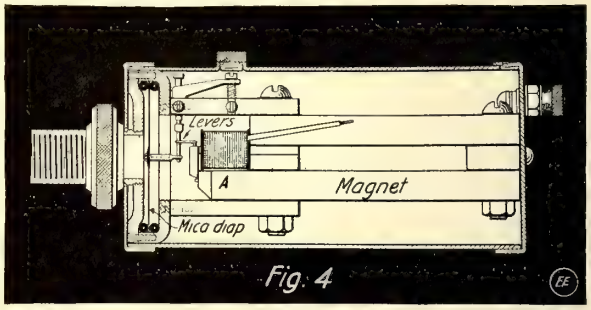

Fig. 4. Reproducer Construction Details.

The reproduced speech from the loud talkers can be heard over distances of 500 to 600 feet, and the articulation is very distinct and perfect; if anything, more so than when holding conversation over the ordinary telephone.

WATERPROOF CEMENT OR CELLULOID.

Celluloid is becoming increasingly popular as a material for making a great many articles. Broken parts are sometimes cemented with a form of glue, made by melting gelatine in sufficient glacial acetic acid to cover it by means of gentle heat, after first standing for 24 hours in the cold. This cement, while strong, is not waterproof. A better cement, and one that will withstand the action of water, can be made by dissolving small cuttings of celluloid in acetone to the consistency of a thick syrup. After applying this solution to the parts that are to be united the work must be placed under pressure and left for some time until the cement is quite hard.

PRODUCTION OF MICA IN 1914.

The value of the mica produced in the United States in 1914 was $328,746, a decrease of $107,314 from 1913, according to a statement of Douglas B. Sterrett, of the United States Geological Survey. The production came from 13 States. The output of sheet mica amounted to 556,933 pounds, valued at $277,330, as compared with 1,700,677 pounds, valued at $353,517, in 1913, and the production of scrap mica in 1914 amounted to 3,730 short tons, valued at $51,416 as compared with 5,322 short tons, valued at $82,543, in 1913.

There was also a decline in imports of unmanufactured and trimmed mica.

A METER, SOME SPIDERS AND A MOTH BALL.

Electric meters in the earlier days of the industry were not always made dust-proof. In fact, it was often possible for wily patrons of some electric light companies to introduce spiders into their meters through cracks in the cases. One spider if introduced promptly after the meter was read would spin enough web, it was learned, to retard the meter disc and to effect a considerable reduction in the electric light bill. According to stories told by operators of those early days, a single moth ball if placed in each meter case could be depended upon to eliminate all trouble from spiders.

Some Late Theories for the Young Scientist

By Rogers D. Rusk, Science Dept., Defiance, O., High School

HERE in the United States we have a vast army of boy scientists and experimenters from whose ranks the masters of theory and the practical inventors of to-morrow will arise. A deal more would be accomplished and a greater number of these budding geniuses would be more surely successful, if they had proper guidance in their early efforts. The writer wishes in the present article to point out a few of the more important theories of the day and the opportunity for their further development.

Men, from time immemorial, have pondered on the great questions of this life, and the ancients who spent their lives in search of rich truths were known as philosophers. Very soon philosophy was divided into two great divisions: one being the study of life, its reason and purpose, and the other being a study of matter and force and all the phenomena of nature. From this the latter was called natural philosophy, or, as we now know it, the science of physics.

Many have been the theories regarding the construction of matter from the subjective theory that matter exists only in the mind, to our latest, the electronic theory. The atomic theory of matter, of which the electronic theory is only a deeper interpretation, has become so well founded and satisfying that scientists now never doubt its general validity, but the farther and farther we study, the more we see that all theories are more or less *glittering generalities,* whose greatest use is to give us room to stand on while we endeavor to grope and feel a little farther.

Matter was first found to be divisible into small particles known as *molecules.* These were the smallest particles of a substance which would still retain their original characteristics, and these molecules it was later found could still be divided into the different elements or particles of which they were composed, and these smallest divisions were called *atoms.* It remained now only to find what the atom was made of to know the actual constitution of matter.

In the last few years experiments have proved that the atom is a kind of miniature universe all in itself, and that there seems to be a central body or nucleus and other particles or *electrons* as they are called, revolving about the nucleus, at a probably very great relative distance from it. Certainly our universe seems as infinitely extensive toward the minute as it is limitless in the opposite direction, and few of us realize how probable it is that each universe is only an infinity of smaller ones.

The electron theory is a big step in scientific advance, for now we see that it is possible for all the different kinds of matter to have the same fundamental constitution of nuclei and electrons except in a different number and arrangement. Just what may cause any particular arrangement, whether from internal or external forces, is a big question, and one which will probably puzzle scientists for a long time to come.

The fundamental unity of matter has been the pet theory of many scientists, but a difficult one indeed to prove. A fact often employed to substantiate this theory is found in astronomy. By means of the "spectroscope," the different elements of the stars and planets may be analyzed and in the very young nebulae, which are solar systems in the making, only a few elements are found; while in nebulae in more advanced stages of development, more and more elements are found, until finally the greatest number is found in the older bodies, such as the planets of our solar system.

This seems to point to the fact that as matter gradually goes through the process of evolution more and more different forms are evolved from some common fundamental base.

The electron theory has, moreover, simplified our concepts of heat, light and electricity. A few years ago there was hardly a scientist who would venture a guess as to the nature of electricity. Now the electron has given us a good foothold in theorizing. The Zeeman effect, cathode rays and other phenomena, have by a reverse process, helped to establish the electron theory and Prof. Millikan of Chicago has actually succeeded in *isolating and measuring the electron itself;* which he found to be about one two-thousandth the size of a hydrogen atom. In static electricity and the study of the various electric tubes, the electron theory is particularly applicable and demonstratable.

The chemist has been in the dark for a long time on the attraction certain elements manifest for other elements, and this he has named *chemical affinity.* The power of uniting he has termed *valence;* and as in water oxygen unites with two parts of hydrogen whose valence is taken as unity, we say the oxygen has consequently a valence of two. The electron theory opens up with renewed interest the question of valence and what it really is. If it depends on the structure of the atom, and all atoms have the same fundamental constitution, only differing in arrangement and number, then valence ought to vary accordingly. If it does not, and it certainly seems that it does not, then evidently the field here is just opening up.

Physical science may be pretty well summed up in the three categories, matter, ether and energy, and artificial as these divisions no doubt are, they serve the purpose to designate three great fields for research. Of matter enough has already been said and of the various forces which await further investigation might be mentioned, adhesion, cohesion, gravitation and magnetism; the last being not the least interesting, indeed.

Regarding *energy,* we know as little about it as anything else, or as Thomas A. Edison has said: "I calculate we know less than the one-ten millionth part about anything." One of the latest theories is known as the Quantum theory proposed by Planck and adhered to in some form or other by a number of scientists. It is to the effect that *energy,* instead of being a continuous and infinitely divisible quantity as heretofore believed, is discontinuous and resolvable into elemental units or atoms of energy. This is similar to our atomic theory of matter and there is good ground for argument on both sides.

Of the *ether* our knowledge is practically nil, except that it transmits light and light waves according to Maxwell as transverse electro-magnetic vibrations. Here again the electron is dragged in with the electro-magnetic theory. The connection between energy, matter and ether seems indissoluble, and the farther we advance in science the more we see how all natural laws work in harmony, and how it resolves that it is our woeful lack of knowledge that causes us to fail to see the relations and infinite truths of nature.

Recent developments in wireless telegraphy and radiation have opened up new fields of investigation, the results of which only aid us the more in former fields. We are now at a place where we are not hampered by a meaningless jumble of phenomena and (empirical and individual mostly in those days) laws, as the scientists of a few centuries ago were. Our general science of physics is fairly well organized and looking out we can see the vast fields open ahead of us.

Showing the Relation of the Basis of Matter, According to the Latest Scientific Theories.

Omegon

By George Frederic Stratton

NED CAWTHORNE, the young millionaire heir of the founder of the great Cawthorne Electrical Works, glared at the half-page caption in the morning paper:

INTENSE EXCITEMENT IN WASHINGTON

Reports That Seventy Thousand Japs and Chinese Have Been Smuggled Into Mexico During the Last Ninety Days

SECRETARY OF WAR ARMSTEAD IMPERATIVELY SUMMONED FROM FLORIDA

Rumor That Mobilization of U. S. Troops Will Commence At Once

He dropped his elbows on the table and his clenched fists against each side of his strong lower jaw.

"We'll be in it, at last!" There was almost a piteous moan in his low, deep voice. "And I—smashed in that accursed polo game—am on the bench."

He straightened up, crashed his fist on the table and growled: "Ever since this fearful struggle in Europe—always with the chance that our country would be drawn into it—I've been ready. I could raise a troop in a week in Idaho and Wyoming. I'd do it, if I had to mount and equip them myself. And now—now, I'm crippled and useless!"

His man, Frohm, entered the room and announced: "Mr. Kilroth, sir!"

Cawthorne glanced at the big, sturdy mechanic who followed. Then he limped forward with a cordially outstretched hand.

"We know each other by sight, no doubt, Mr. Kilroth; but I've never exchanged any words with you, I think."

"You've seen me in the works, sir. They call me a shop inventor."

"And you have something to submit to me, Kilroth?"

"Yes. The men and the engineers know well how you feel about this war and what you'd like to do; and I've heard of something—a big thing—you can do if you care to put in the money and give orders."

He glanced at Cawthorne, who, with clenched jaws and fiercely flashing eyes, nodded imperatively.

"It's no invention of mine, sir, but I've heard of it and looked into it. It's a submarine invented several years ago. It will run under an armored vessel, and in twenty minutes, or less, all action on that vessel will cease, although no lives need be sacrificed and no damage done to the ship."

Cawthorne's fist crashed down on the table. "If it will do that, Kilroth, why has it not been developed?"

"It doesn't kill," retorted the machinist. "It's been offered to the Government and turned down, flat. It's too small and unimpressive! It's only forty feet long and hasn't got a death-dealing implement on board. Its purpose is persuasion, not annihilation, and the War Department don't take any stock in that kind of stunt."

"Where is it?" demanded Cawthorne.

"There's a model in Providence, and full drawings. The inventor, Wheaton, is a Providence man."

"Can we see it—and when?"

"To-day, if we were there, Mr. Cawthorne."

"We'll be there!" He picked up his house phone, called the hangar, and directed:

"Wansted! Get that gyroplane ready for a trip, at once. Just three or four hundred miles." Then turning to Kilroth:

"You can go, I suppose?"

"Certainly, sir."

The elder Cawthorne's grasp on gigantic industrial exploitations and the financial projects which backed them had notoriously come from his marvelously rapid decisions and determinate action; and Ned was his father's son. The flight over to Providence, the interview with Wheaton and the convincing enthusiasm of the machinist, Kilroth, resulted on that same day in a decision to build some of those submarines. Ned spent a week in placing orders, at several great plants for the shells of the boats and for the various parts of the machinery and equipment. Then he dashed across the continent and secured a large water-front warehouse for the assembling and launching of the boats.

The magic of the Cawthorne name and the two hundred millions back of it, with Ned's evident disregard of cost, resulted in astounding speed in those great shops, and several cars of apparatus were being rushed west by special train when war with the Japo-Chinese alliance was declared.

Kilroth engaged a number of the finest machinists from among his very extensive acquaintance, but not one was informed clearly of the work to be done.

"It's assembling machinery over in San Francisco," he stated. "You'll get triple pay and all expenses; but you'll have to stay and live in the shop till the job's finished. The doors'll be locked when you go in, and they'll stay locked till we're through. Even your mail will be censored! If that doesn't suit you, don't go."

SUPPOSE that some first-class foreign power declares war on us to-morrow. Also suppose that we are outclassed in battleships—we are only the fourth strongest naval power to-day—what would happen? Would American genius prevail? Would our inventors rise to the occasion? Could we annihilate a powerful fleet as suggested in this story? Read this brilliant tale and judge for yourself. It will fire your imagination and it will thrill you, as few stories can.

And, amid all the tremendous excitement of preparation for war, the rush of troops to the Mexican border and the rush of battleships through the canal and along the Pacific Coast, the mystery of the big, sealed-up warehouse in Oakland excited intense speculation from coast to coast. News correspondents made frantic and futile efforts to get admission to the building or into touch with some workman, but the only man who ever responded to the demands at the entrance was Kilroth.

"Nothin' doing!" he'd grin through the small wicket. "You'll have to see Mr. Cawthorne."

That gentleman invariably received them with hearty smiles, cigars and: "Oh, well, boys! Of course you know we're working on some small—very small—submarines; just experimental models, in fact. If they show any promise I shall invite the naval authorities to look at them."

And when the naval authorities were invited to inspect the boats a young lieutenant was sent to the shops. He glanced superciliously at the five miniature boats ranged along the length of the floor and, with a touch of sarcasm in his tones, said:

"A bit small for present warfare, Mr. Cawthorne. The total length of those five boats is considerably less than any one of the new boats they're laying down at the Fore River shipyard."

Ned laughed: "Sometimes machines are like men; the size is no indication of efficiency, lieutenant."

"Possibly so, in industrial matters. But making cotton-cloth or—er—arc lamps is not warfare. It's weight counts there. That last battleship the Japs put into commission is fifteen feet longer than any we've got, and her guns are three millimeters larger caliber. That's what we've got to meet."

Ned shrugged his shoulders. "Examine the principle of this boat. See those great electro-magnets on the deck? When we run under a battleship those magnets will be switched in and hold this little forty-foot submarine as fast against the great hulk as if she was bolted. Each magnet has a pull of 20,000 pounds! Now! Look at these guns pointing straight up from the interior of the boat. Just a little two and a half-inch bore, but they use the new Trotal gelatin explosive. They put as much power behind a bolt as the most modern fourteen-inch gun you've got. Let's go inside!"

They descended through the deck manhole, and in the ample light of electric bulbs the lieutenant saw two bulkheads—the doors open. Aft was the 300-horsepower Hargreaves motor, its aluminum casing and duplex wiring weighing only one-quarter as much as the ordinary motor of the same power.

"Our current is from the marvelous Edison-Seabright storage culminator," explained Ned. "No compressed air to heat up things. The voltage is 2,000, and there's juice enough to run us 600 miles."

The middle compartment contained the controlling mechanism, the gauges, air and pressure valves, and, overhead, the collapsible conning tower. Forward were the breeches of the two Tobin bronze guns, and tapped into each was a flexible tube connecting with chemical tanks overhead.

The lieutenant pursed his lips. "The department has seen drawings of all this before, Mr. Cawthorne. Ingenious, and all that, but giving no indication of practicability."

Cawthorne exploded: "No indication of practicability! How can such a demonstration be made except in actual use?"

"Ah, yes. Of course! But, don't you

see, my dear Cawthorne, that this is no time for experimentation? We have got to fight the real things, and must have the real things to fight with. I should advise you to make a test on some hulk. There's quite a number of played-out tramp steamers laid up here."

Ned's face crimsoned with riotous indignation and a hot retort sprang to his lips, but the lieutenant had stepped to the manhole ladder and started to ascend. He paused on the lower rung and continued:

"Of course, all that is only my opinion, Mr. Cawthorne. I shall make a full report of this, and you will probably hear from my superior officers regarding it."

But as quickly as the hot wave of rage had swept over Ned so quickly it departed, and in its place came a flashing gleam of inspiration. "That hulk!" he muttered, as he skilfully worked his false leg up the ladder steps. "This little lieutenant has put me on the track of success far more than he thinks!

He waved his hand to the departing officer, stumped over to a shed and ran out his roadster. Before that day was out he had signed a check for $120,000 for a laid-up tramp steamer, formerly in the Columbia River lumber trade.

And that evening San Francisco was wild with excitement and alarm over the telegrams:

"Seven Japo-Chinese superdreadnaughts crossing the Pacific, headed for San Francisco. Six others have left Mexico and are steaming north."

Cawthorne dashed down to the big warehouse and got Kilroth into the eight-by-ten den they used for consultation.

"How soon can we run those boats out?" he demanded.

"Three days! There's a conducting wire all ready for charging our culminators and the tanks are connected up, ready for the chemicals."

"Yes!" retorted Cawthorne grimly. "And do you know what we're up against now? That naval expert who was here this morning has nothing but sneers for our boats. They're not large enough to consider. Now, Kilroth, unless we man those boats ourselves, and fight them ourselves, they'll stay right here on the floor. I haven't the faintest hope that the naval authorities will put them in commission!"

"I never had!" grinned Kilroth. "But we can handle them. We'll need three men for each boat—four would be better—and we can get the right fellows from our gang here. They don't know how to present arms and salute a dinky little West Pointer properly, but they'll put those boats just where we built them to be put, mark me, Mr. Cawthorne."

Ned grinned confidently "I'm sure of it!" Then he told of the lieutenant's suggestion to test the submarines on some old hulk.

"I bought the hulk to-day," he laughed. "Not to test the submarines—we'll do that on a Jap dreadnaught—but as a tender. See! She's a pretty fair boat. Now, here's my plan: If the authorities here knew that we were going out to meet the enemy they'd stop us completely; but they're not going to know it until it's done. We'll state that we're going up the coast to test the boats, and we'll start up that way; but after we've run a hundred miles north we'll change into the west and run out into the Pacific and intercept those Japs seventy or eighty miles from San Francisco. Our steamship will cover our approach, will tow us out until she is challenged, and save our power. Then we'll drop our submarines below the surface and go for them."

"That's a scheme, all right," grinned Kilroth. "An innocent looking little scheme that hasn't got any 14-inch guns poking out in front of it."

"Select the men we need," muttered Ned. "Tell them just what we're going into, and that I'll guarantee them a couple of thousand dollars each for the adventure—win or lose. And there may be prize money! If so, it will be big—very big! Now, I've got to select a captain for that hulk—the *Sarah Quimby*."

Four days later the *Sarah Q.* steamed out of San Francisco Bay, and grouped at her stern were the five submarines, decks awash, the tiny conning towers barely visible. They ran up the coast to Gualala, and while the *Sarah Q.* lay at anchor the submarines made below-the-surface cruises, testing out men and equipment.

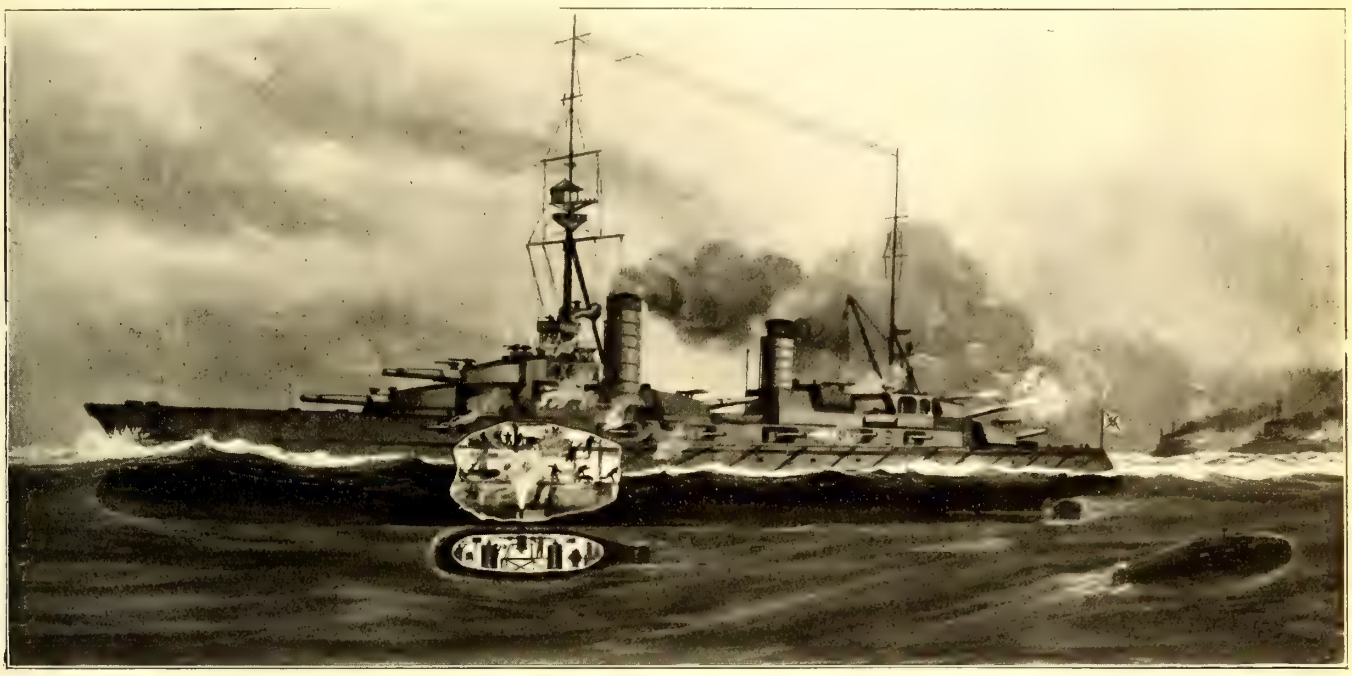
There were two days of that. Then came, through the Gualala telegraph office, a code message from San Francisco, sent by one of Cawthorne's trusted mechanics, and which Ned interpreted as:

"Wireless from outlying scout cruisers—Jap vessels 200 miles west."

He handed that to Pat Mulray, the new captain of the tramp steamer, and that blue-eyed, red-haired mariner gleamed with joyful anticipation.

"If we start at once, Mr. Cawthorne, we'll cut 'em off a hundred miles out of 'Frisco Bay. That'll be about right, won't it?"

"It sure will, Captain. Admiral Sangster's squadron won't run out as far as that to meet them. He's got to keep near the coast to watch those other Jap ships which are working up from Mexico. Now, you've got it all clear. Run across the line of the enemy's ships. They'll challenge you as soon as you get within five miles—perhaps before. Then you'll lower your flag and stop. They'll send a prize crew aboard, I suppose, and make you and your crew prisoners; but about that time we'll be busy."



"Glory be! I'd like to be goin' wid yez, Mr. Cawthorne. It's against the grain to be lowerin' the flag to those little brown divils."

"It's the strategy of war, Captain. You'll have the laugh on them a little later."

They steamed out, due west, the conning towers of the submarines just above water, but hidden along the side of the *Sarah Q.* At noon two cruisers, which had been watching outside, were working back toward the coast. They sent an imperative wireless message:

"Turn back! The enemy's battleships are coming in." To which Captain Mulray returned:

"Thanks. Going due south. Will be across before they get here." And for 20 minutes he changed his course so as to avoid any interference from those cruisers.

The gun piston had plunged through the bottom plating of the ship, carrying with it the Omegon ether injection tube.

Then he swung her head again into the west and ran at full speed.

When within 10 miles of the coming vessels Cawthorne gave the order:

"Drop below!" and in a few moments the conning towers had disappeared. At 16 feet below the surface the boats kept together, running at full speed. Ned's boat, No. 3, was in communication with each of the others by means of the new hydrophones which were perfected to an underwater radius of 5,000 yards, and his aerial televisor, floating like a little toy balloon 20 feet above the surface of the water, was showing on the marvelous electric screen below the positions of the battleships.

"They're running half speed!" he exclaimed, exultantly. "Look at the funnels! No forced draft there! I'll bet they are holding back so that their southern squadron'll reach San Francisco when they do. That'll give them 13 ships against Sangster's 11."

When within two miles of the ships the televisors were hauled down. Ned gave his last orders to the other boats, and each started independently on its mission. They darted through the smooth subsurface at full speed, and in less than five minutes the magneto-detector in Cawthorne's boat showed the nearness of a mass of steel, its needle pointing accurately to that mass. Ned steered to one side of his prey, swung sharply around and darted under the monster—the flagship of the Japo-Chinese alliance and the most furious hell of destruction ever constructed by man.

"Half speed!" he yelled, and Bundy slipped the controlling lever over. Wheatly, the third man, stood by the submerging wheel.

"Up—easy!" commanded Cawthorne. Then he sprang to the forward magnet while Bundy jumped for the other, and there was a dull thud and scraping sound as the magnets of the submarine came up into contact with the bottom of the *Matzuma.*

"Hold her!" he shouted, and threw his switch, and the distinct jar and click showed that the connection was made.

Cawthorne peered from the bullseye in the tiny lookout, just large enough to take his head, and he threw on the concentrated electro-magnese ray. "Pretty well forward," he muttered. "Jump for that forward gun, Bundy! Fire it!" and the next moment there was a crash which jarred every rivet in the boat. *The gun piston had plunged through the bottom plating of the ship, carrying with it the injection tube.*

"Stand by that pressure valve! Let her go!"

Wheatly swung the valve, opening connection to the chemical tank above and forcing the *Omegon* ether, under 300 pounds pressure, through the gun piston tube into the bowels of the great superdreadnaught. Cawthorne stepped to the pressure gauge and watched it for eight minutes, which seemed like eight days to the other men. Then, his face grinning through a flood of sweat, he exclaimed:

"We'll give them the other tank in the other end now. Stand by those magnet switches! Throw 'em out!"

The great magnets went out of commission and Cawthorne threw in the propeller switch, casting off so as to permit the submarine to slip along the bottom of the battleship toward the stern. Suddenly he yelled, "Hold her!" and again the magnets took their bull-dog grip on the steel plating.

Again and again came the fearful crash of the great guns above them. "They're firing on the cruisers, I guess," grunted Ned. "Let 'em have that other gun, Bundy!" and he sprang to the pressure valve. The operation on the forward end of the ship was repeated aft, and as Cawthorne's eyes were fastened on the gauge, Wheatly exclaimed:

"It's getting in its work, Cawthorne! The for'rd guns are silent!"

"Well, we've done all we can," grinned Ned. "Let's get out of this!"

Again the magnets were switched off, the propeller motors put into action, and the nose of the submarine pointed down as they darted away from the bottom of the huge dreadnaught.

They ran for two miles before raising the televisor. Then it was allowed to float up to the limit of its 40-foot cable. Cawthorne's eyes were fixed on the wonderful screen which revealed all that the televisic eye above saw. Wheatly stood by him, every nerve tingling with excitement.

"The *Matzuma's* engines are stopped!" he half yelled. "See those funnels!"

"There's the *Sarah Q.!*" grinned Cawthorne, as the televisor was slowly revolved. "Flying the Japo-Chinese flag, too! They took possession of her pretty quick. I wonder what Captain Mulray's doing?"

MÜNCHHAUSEN?

YES, how about him, what happened to the old boy? Was he really struck by a meteor and was he killed? No, dear readers, nothing of the sort happened. Meteors may be fast, but not fast enough to catch our beloved Baron, no sir.

To explain: When the usual installment did not arrive from our far famed correspondent, I. M. Alier, of Yankton, we sent him several urgent wireless messages. Here is his answer:

Editor E.E., New York:

Sorry no installment this month. Münchhausen and Prof. Flitternix left for Planet Mars in their "Interstellar" some time ago. Will return to Moon, Sept. 10th. Expect sensational story. Hold presses till last moment to catch October issue.

I. M. ALIER.

The above explains it. If everything goes well, we ought to print a wonderful story in the October issue. We're kind of excited to know what's doin' on Mars, aren't you? Better order your October issue now.

"Our battleships are coming up!" he added after a short pause. "If our submarines didn't get in their work there'll be a fight, right out here. But four of the enemy's vessels are not steaming, and our cruisers are falling back to meet Sangster's ships. I guess we'll fall back too, Wheatly. We ought to report what we've done so that the Admiral can follow it up."

They headed back east at full speed, and in a few minutes were near the *Texas,* which was turning her propellers just sufficient to give her steerage way. Flying the Stars and Stripes from the aerial mast, Cawthorne put his short wireless into action.

"*Texas:* Can I come alongside and report? Our submarines have been in action and have silenced four of the enemy's ships, I think."

There was a few minutes' delay. Then came the answer: "Come alongside."

Five minutes later Ned climbed onto the deck of the cruiser and faced the lieutenant who had inspected his boats.

"We have discharged our Omegon ether into the *Matzuma,*" he exclaimed, "and I believe, from the appearance of the enemy's ships, that three of the other submarines have done the same!"

"Good Lord!" ejaculated the officer, "is that what it means? Come aft, Mr. Cawthorne, and report to the Commander."

He was taken to the bridge and again stated what he had done. Commander Preston made no comment, except: "Four of their boats are out of action—are not even steaming. Mr. Pearsall! Direct the wireless officer to report this information to the Admiral. Mr. Cawthorne, go onto the main deck, or below, if you wish. One of their vessels is getting our range."

He went to the deck, and as he reached there a fearful, ear-splitting crash broke out astern. Staggering around, he saw the gigantic *Arizona* about a mile away. Then a hand was clapped on his shoulder and a deep voice said:

"Mr. Cawthorne, I believe?"

It was the ship's surgeon. Without waiting for a reply, he went on: "Something extraordinary has happened, or is happening. Three or four of the enemy's ships are out of action, and our Commander has just been signaled to send a prize crew aboard the *Matzuma.*"

"The *Matzuma!* The vessel we put to sleep?"

"Evidently. Her flag is down." Then, after a long glance through his binoculars, he added: "I make out two other ships—flags down!"

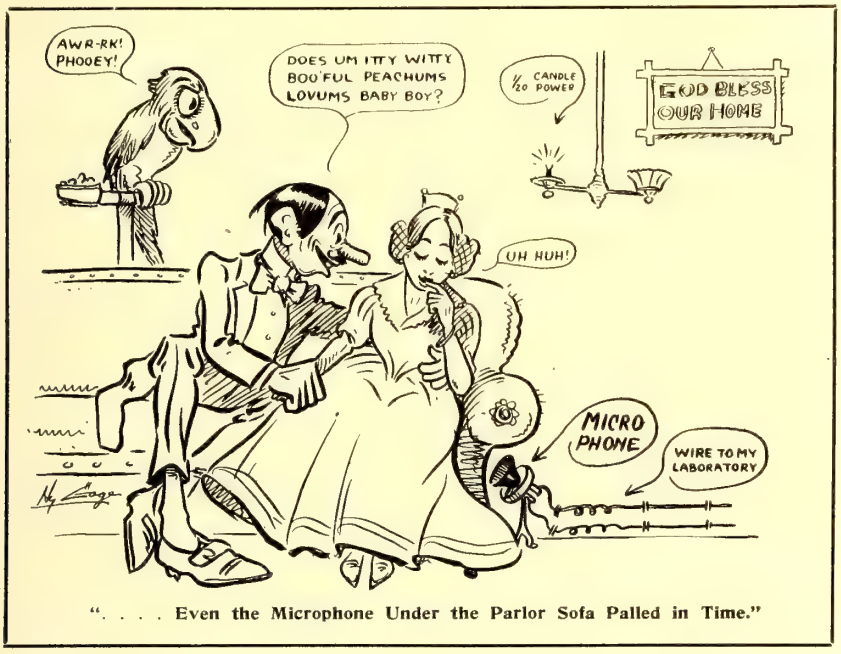
"Then my submarines did get in some work," muttered Ned. "I'd give a million to hear from them—to learn if they are safe. Surgeon, is there a bare possibility of calling Gualala? I ordered those boats to run back there when they got through."

The officer shrugged his shoulders. "I think we all feel curious about that. Stay here, Mr. Cawthorne. I'll see the Commander."

In a few minutes he was back. "The Commander has ordered communication with Gualala. He's as eager as you to know how your men and boats have come through. It's marvelous, simply marvelous! Five of those tremendous new superdreadnaughts have surrendered without landing a shot! Most of the firing came from the two which our ships are now chasing! Here comes our launch—the one that took the prize crew out to the *Matzuma.*"

And as the officer in command of the launch came on board he was followed by Pat Mulray, captain of the *Sarah Q.* Utterly indifferent to the uniformed men about him and the officers on the bridge, he made for Cawthorne in an Irish hornpipe step which was a revelation of irrepressible overwhelming joy.

"Glory be! Man, dear, yez did it! Hould on, now! Hould on! I'll tell yez all about it if ye'll let me lay me own course. Whin the *Matzuma* sint a launch over to take possession of the *Sarah Q.* they had orders to take me back to the flagship. So I wint. Whin I got there they began askin' me about th' little *Sarah,* an' what I was doin' wid her out there. But divil a wor-rd about th' submarines. They knew nothin' of thim, at that toime; but they got th' knowledge of thim without askin' me. Before they asked me more than twinty questions an' got th' neat little lies I had ready for 'em, the for'rd guns stopped firin' an' th' officers an' deck crew were tearin' 'round, crazy as hornets. They opened some hatches an' jumped in, an' came out again carryin' out men as limp as dead eels, an' laid 'em 'round th' turret base like bars in a capstan.



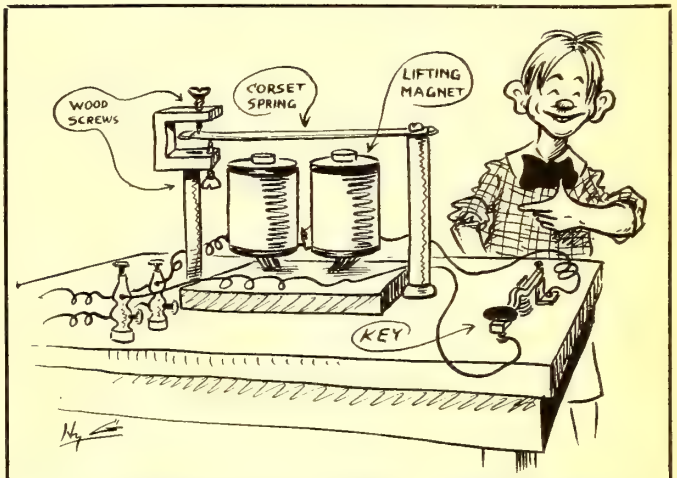
(*Continued on page* 237.)

The Old "Bug" Speaks

By Thomas Reed

IN many hearts the warmest spot is reserved for the boy experimenter, the "scientific bug." In mine that spot is so large that it threatens to include the entire organ. Do I know anything about bugdom? Listen.

The youthful bug is always poor. His scanty finances have to be spread as thin as a coat of paint over the vast area of his desires. How we envied the lot of the fortunate exception, the boy whose parents "encouraged" his taste, giving him unstined "dough" wherewith he acquired "boughten" instruments, driving us to what in later years would be drink. Long, long afterwards we knew that the favored child of fortune was missing all the fun of the thing. Once the oh's and ah's of the have-nots had died away he had nothing to do but turn his nickeled handles and grow tired of his toy; while we progressed from one triumph to another, conquering not only the forces of nature, but the attacks of "outrageous fortune." The first was easier than the second.



". . . . Even the Microphone Under the Parlor Sofa Palled in Time."

Bits of material and parts from other mechanisms were our hoarded wealth. Clock movements and curtain rollers were mines of opportunity. Broken electric light carbons and sheets of lead-foil from the tea-chest were what the solemn ones call "mediums of exchange." Feminine finery helped the cause—what should we have done without the trusty corset steel? It was supplemented in my day by the flat wires of the last of the hoop-skirts, ravished from its dusty retirement in the attic.

With us it was not to copy, but to extract the principle and adapt to it such material as we had. My first sounder was a big lifting magnet, with an armature of that corset steel of grateful memory, all imbedded in a wooden block with an adjustment contrived of wood screws. It resembled no sounder since the days of Morse, but it worked.

It was in the days of my early *bughood* that the telephone swam into the ken of a waiting world, surrounded by an awesome halo of patent suits. We used to tremble at the step of the policeman on the beat, apprehensive of what the American Bell Telephone Company would do to us if they should catch us with the goods—our poor little wooden receivers made in defiance of the great seal on those patents; but somehow we escaped the felon's cell.

It was the telephone that first broadened the horizon of us bugs. Before that there was only the telegraph, electric bells to ring for purposes supposed to be useful, electric clocks and such like. Oh, yes, an electric wind-vane; to be sure, there was already a vane on a barn in full view of my window, but I persuaded myself mine was more accurate. The telephone began to realize the ideal which has attained its full glory in the wireless. It was a really delicate instrument, yet so easy to make as almost to defy the possibility of failure. Bugdom was elated when its first pair of receivers transmitted words, not only perfectly, but with the individual characteristics of the voice; but given a magnet, a little coil of wire and a diaphragm, and it would tax the stupidity of the head bungler from Bungleville to make one that would not work.

My First Telegraph Sounder Comprised a "Lifting Magnet" of Heroic Size, Together With a Corset Spring and Some Wood Screws.

Of course, I am a wireless bug to-day; but I sometimes wonder, looking back to the lean old times, if the present buglets realize what a seventh heaven they were born into by wisely postponing their birth date till now. Our old machines seemed somehow to lack a vital use. The electric bell that repeated in our room the blows of the kitchen clock was entertaining, but superfluous. The telephone and telegraph once perfected we found it a bore to think of something to say. The wind vane, rain gauge, etc., recorded only slow processes of nature; it was a long wait between changes. The electric clock was good, but monotonous. Even the microphone under the parlor sofa palled in time; variety again was lacking. We yearned for something that, once in operation, would bring us returns from the outer world—continuous, changing, worth while—and there was nothing till the wireless came.

But now what a paradise for the patient bug! Instruments, the coil, the detector, the condenser, within the power of anyone to make. And once made, like the glittering paraphernalia of the wizard, they open a wide door into a new world. You push your sliders, turn your switches, feel for that elusive sensitive spot on your galena, and presto! "the world is all before you where to choose." You hear the fussing of the amateurs from near and far with "O. M.," "C. U. L." and "How is my wave now?" The crisp, abbreviated messages between ships and from ship to shore—here comes the Campania, the Lusitania (alas, no more) just on time, and what a babble is exchanging of "Greeting" and "Love" and "Meet you at the dock."

Here is the weather forecast for to-morrow, hot off the griddle at the navy yard; almost equally important, the baseball scores after the playing is finished for the day. The correct time, straight from old Father Time himself at Washington. The weather conditions in their simple code from a dozen stations; the "winds for Tuesday and Wednesday—North Atl., Middle Atl.," and all around to the Great Lakes Some times the brief, grim tale of an "obstruction to navigation"—an iceberg, a waterlogged schooner in such and such a latitude and longitude. Careful Grandma Wellfleet with her "latest news of the day" —what a boon at the summer camp, where the morning paper will not come in till afternoon, if it comes at all! And so on till the German station starts its all-night toil, rapid, nervous, now in German words, now in English, pouring urgent messages over an iron-bound frontier and a zone of desolation and death.

ELECTRICAL EXPORTS TO ARGENTINE REPUBLIC.

May exports of Argentina from the port of New York included $63,000 worth of electrical supplies. To Brazil, there was sent in May from New York, $34,000 worth of electrical material and supplies.

WHAT IS A WATT?

By P. W. Pelts.

The writer has been asked so often, "How many volts is in an ampere?" and, "What is a kilowatt?" that he has thought of mimeographing the answers and carrying them around in his pocket. However, since the *Electrical Experimenter* is read by practically everyone interested in the subject, a contribution to this excellent magazine would be more far reaching than the typewritten copies would be.

Although we can neither see nor hear the electric current, still it is just as easily handled and utilized as a water fall. Both are sources of energy; both can do work. You can buy and sell the one, just as easily as you can the other. Either can be parcelled off in small packages or sold in job lots. The electric energy can be packed away in small jars and set up on the shelf to "keep," or it may be shot off along a pair of slender metallic threads, to run the shops and street cars of a city three hundred miles away and also light its streets and homes.

Water is sold by the cubic foot or by the gallon. One way or the other, it is a definite quantity, at a definite price. Electricity is sold by the AMPERE*, just as we sell water by the gallon; an AMPERE of current therefore is just "so much." One horse drinks half a gallon of water; twelve horses drink six gallons. One lamp takes half an ampere of current; and twelve lamps require six amperes. A little pony could drink but a small fraction of the gallon, so also a small lamp can take in only a small part of an ampere. A twenty-five watt Mazda lamp uses about one-fourth of an ampere and the 100-watt lamp uses almost a full ampere. An arc-lamp requires from six to ten amperes.

It is well known that some substances will carry the electric current better than others. Silver is one of the very best conductors, with copper a close second. Iron is rather poor, lead is worse, while German silver and Mercury bring up the rear as conductors. Substances that are poor conductors push back against the oncoming current. This ability of a conductor to retard the flow of a current through it, is called resistance, and it is measured in ohms.

A water pipe of small diameter will deliver much less water in a given time than one of larger diameter, although both be connected to the same tank or reservoir. This is because of the resistance offered by the sides of the pipe to the flow of the water. An exactly similar condition exists in an electric circuit. A wire one-fourth of an inch in diameter will offer much less resistance to the flow of an electric current than a wire only one-eighth of an inch in diameter, consequently more amperes of current will flow through the larger wire than through the smaller.

As was said before, the resistance which a substance offers to the flow of electricity is measured in OHMS. The standard OHM is that resistance offered by a column of mercury 106.3 centimeters in length, and one square millimeter in cross-section at 0 degrees C. This is equivalent to a length of mercury 41 4/5 inches and 155/100,000 square inches in area. 9.35 feet of No. 30 copper wire and 6.2 inches of No. 30 German silver wire have the same resistance. 93.5 feet of No. 30 copper wire would have a resistance of 10 OHMS, which would be just the same as 62 inches of German silver wire of the same thickness.

From the above it will be seen that the resistance of a conductor increases with its length and decreases with its diameter, also, that different substances offer different amounts of resistance.

Now since all conductors possess this quality of resistance, and this means that they are able to push back against the oncoming current, we must use force or pressure to push our amperes of current through the conductors so that they may be of use where they are wanted. Take the case of a 55-watt Mazda lamp. The little hair-like filament of this lamp is very small indeed and possesses 220 units of resistance or OHMS. To heat up this filament to full brilliancy we must send through it half an ampere of current. In order to get our half ampere through the lamp we must exert a push or force greater than the backward push (or electrical inertia) exerted by the lamp filament. This force which pushes our half ampere through the lamp, can be measured just the same as the force or pressure of a steam boiler. The unit of this electrical force is the VOLT and it is equal to about two-thirds of the force which can be exerted by an ordinary dry-cell. In other words a single dry cell can furnish a pressure or force of about one and a half VOLTS. It has been found by experiment that the pressure required to force half an ampere through the above mentioned Mazda lamp, is about 110 VOLTS.

Ohm's Law is a formula which enables us to tell what pressure is required in any case, when we know the current and resistance. It is written as follows: VOLTS equals AMPERES times OHMS. ½ AMPERE times 220 OHMS equals 110 VOLTS. If we know the electrical pressure furnished by the power company, and the resistance of a circuit, we can tell before hand how much current will flow. To do this we can transpose the factors in the above formula, so that it will read: AMPERES equal VOLTS divided by OHMS. Thus it is that 110 VOLTS divided by 220 OHMS gives us ½ AMPERE.

Since the power company has to furnish us with the amperes of current to light our lamps, and also the pressure to force the amperes through the lamps, they are going to charge us for both the VOLTS and the AMPERES. Edison's first electricity meters measured only the AMPERES that ran into the customer's lamps, then the bookkeepers in the office had to figure out the rest of the bill. The modern meter, however, measures both AMPERES and VOLTS. In fact it multiplies one by the other and gives the answer in WATTS. A WATT, then, is a VOLT times an AMPERE, and is the unit of power. Half an ampere of current flowing into the lamp for one hour, forced through the lamp by a pressure of 110 volts, gives us 55 watt-hours. If the electric company charges at the rate of 1/100 cent per watt-hour (which is the same as 10 cents per kilowatt-hour) our bill for burning the Mazda lamp for one hour is approximately ½ cent. Thus the consumer of electrical energy will have some idea of how his watt-hour meter "adds up his bill."

[*Not strictly speaking; the watt is the unit of electrical energy. See the author's later paragraphs.—Editor.]

THE WRAITH OF THE WIRELESS

By Rose Seelye-Miller.

I was a voice enthralled,
And at command I called
Over the sea, where the white ships ply
Over gray icebergs, through foggy sky;
Sharply or softly, the vibrant air
Carried my message, shriek, or prayer.

Chanted the watchman, "All is well."
A crash! Pandemonium! Hurry! Hell!
My master's hand clutched at my vibrant throat;
Choking, I hurtled a single note—
In a mad, metallic S. O. S.
I shrieked out my signal of distress.
S. O. S.! S. O. S.! S. O. S.!
I shrilled and I prayed in wildest stress,
Save our souls! Save our souls! Save, Oh, Save!
From the iceberg ghouls and the deep sea grave!

Save! But the hand that hurled me wide
Fell from duty to death in an awful tide.
My Master's power was too weak to save
A mighty horde from a mightier wave.
Had I been mortal, my throat with Death
Would have choked and rattled with frigid breath.

But I live, and Master, Master, I fly
Over fields of ice, through foggy sky,
Futile, finite, hushed and stilled,
Without thy hand that touched and thrilled.
I'm a wandering wraith, without control,
For my voice went out with my Master's Soul.

Some time, somewhere, in infinite light,
I shall answer again to my Master's might.
Neither futile, nor finite, then will be
His hand with its perfect mastery.

EDITOR'S CHAT

We sincerely hope that you will like this issue. Containing as it does 144 illustrations and 128 different articles, it is without a doubt the largest and most complete popular electrical magazine ever printed in this country. No expense was spared to produce this big issue which is the equivalent of an 128-page standard-size magazine. But while it may satisfy you, we are not as yet at the end of our efforts. We will try hard to surpass this number; indeed the coming October issue will even be better.

There will be several big feature articles, several new "cracker jack" stories, including "Münchhausen" on the Planet Mars. There will be a wonderful article for the Constructor and a bunch of new wireless articles to gladden your heart.

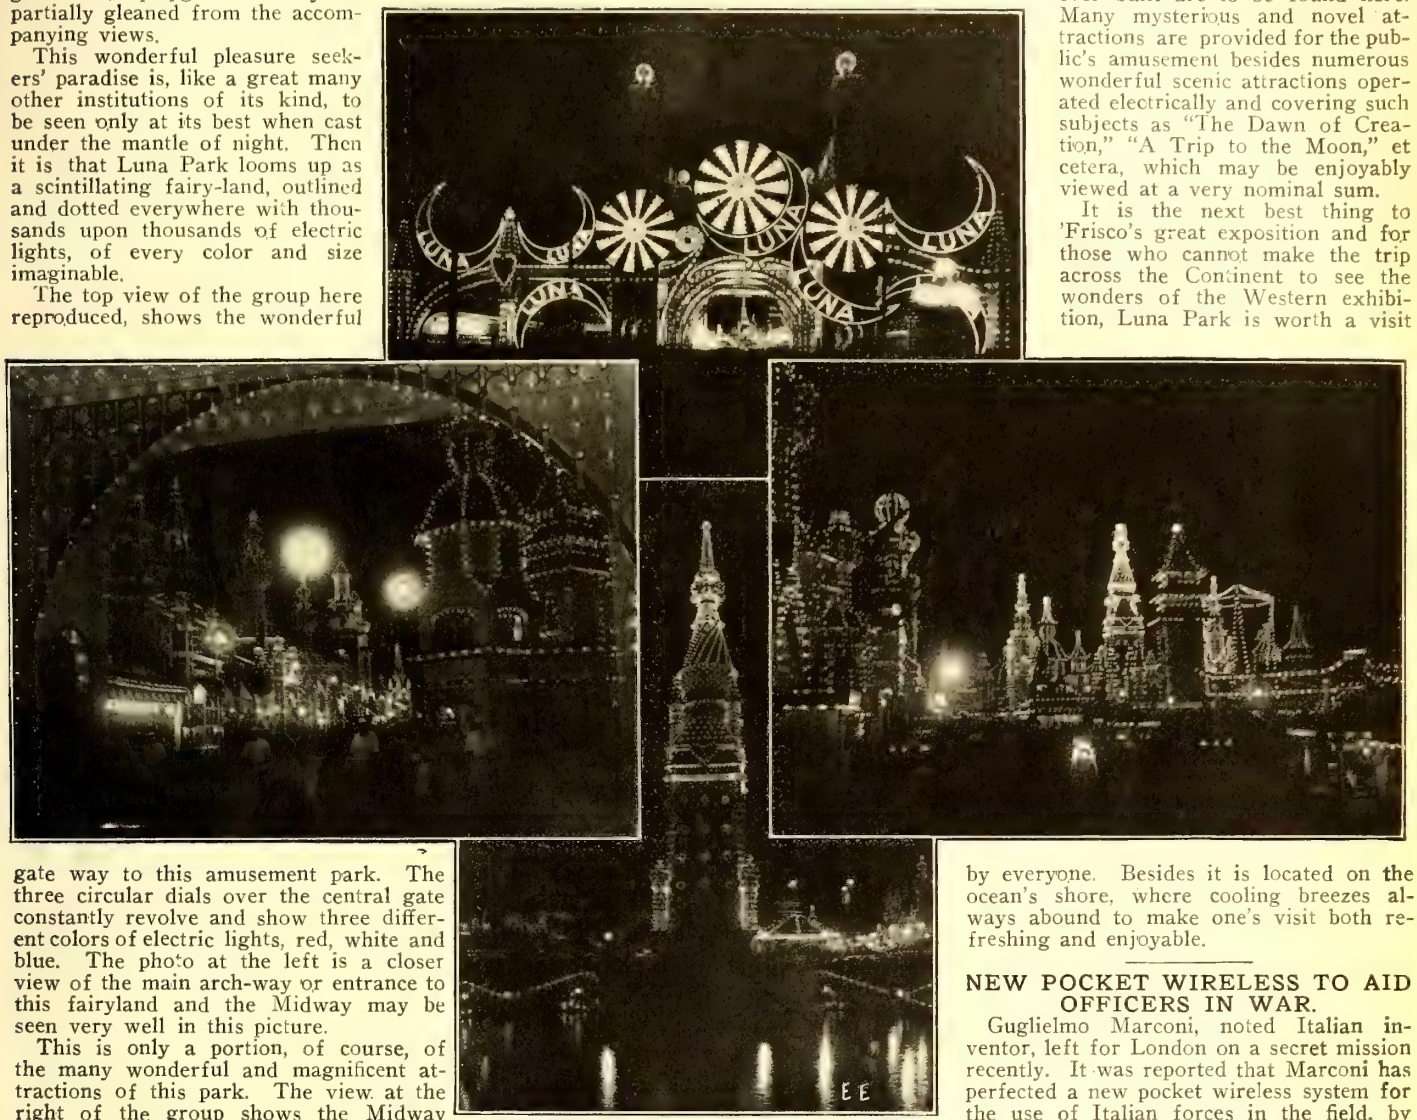
But before we forget it: This issue is so big only due to our advertisers. You must thank them rather than us. You cannot show your appreciation better than by writing for their literature and by patronizing them to the fullest extent. Only—and only so—can we enlarge the magazine still further. It's up to YOU.

And before we forget, order your October issue early, NOW.

Massachusetts students of wireless have had good success with experiments in sending and receiving messages with aerials laid on the ground.

Luna Park, New York's "Joyland"

WHEN the proverbially tired business man of the great metropolis of New York looks about for a place in which to clear away his worries, he invariably jaunts forth to that "Mecca" of all pleasure seekers in the "Eastern" United States, Luna Park. Some of the beautiful effects attained in the arrangement of the electric lighting of this playground of playgrounds may be partially gleaned from the accompanying views.



This wonderful pleasure seekers' paradise is, like a great many other institutions of its kind, to be seen only at its best when cast under the mantle of night. Then it is that Luna Park looms up as a scintillating fairy-land, outlined and dotted everywhere with thousands upon thousands of electric lights, of every color and size imaginable.

The top view of the group here reproduced, shows the wonderful minarets of Luna Park at night.

The lower central photo shows The Tower of Jewels, which is garbed in a handsome manner with thousands of electric bulbs and as this is situated alongside one of the lakes or lagoons of the pleasure ground, the reflection and general scenic effect at night is very entrancing and decidedly oriental. In fact, this seems to be the underlying theme in the general arrangement and architectural layout of Luna Park. This oriental effect, to be sure, gives a bewitching charm and quaintness not easily duplicated otherwise.

There are a great many interesting attractions to be found here, which depend mostly for their operation upon electricity. The largest scenic railways and the like ever built are to be found here. Many mysterious and novel attractions are provided for the public's amusement besides numerous wonderful scenic attractions operated electrically and covering such subjects as "The Dawn of Creation," "A Trip to the Moon," et cetera, which may be enjoyably viewed at a very nominal sum.

It is the next best thing to 'Frisco's great exposition and for those who cannot make the trip across the Continent to see the wonders of the Western exhibition, Luna Park is worth a visit by everyone. Besides it is located on the ocean's shore, where cooling breezes always abound to make one's visit both refreshing and enjoyable.

Views of the Beautiful Night Illumination at Luna Park, New York.

gate way to this amusement park. The three circular dials over the central gate constantly revolve and show three different colors of electric lights, red, white and blue. The photo at the left is a closer view of the main arch-way or entrance to this fairyland and the Midway may be seen very well in this picture.

This is only a portion, of course, of the many wonderful and magnificent attractions of this park. The view at the right of the group shows the Midway more in detail and here can be seen the many beautiful illuminated towers and

NEW POCKET WIRELESS TO AID OFFICERS IN WAR.

Guglielmo Marconi, noted Italian inventor, left for London on a secret mission recently. It was reported that Marconi has perfected a new pocket wireless system for the use of Italian forces in the field, by which officers at the front can keep in touch with headquarters all the time.

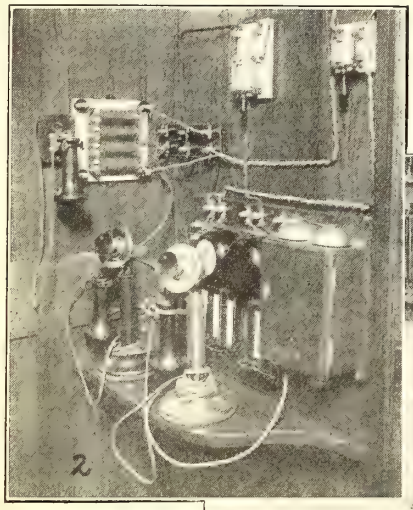
UNCLE SAM WILL HAVE ELECTRIC BATTLESHIP.

The first electric battleship will be added to the United States navy in two years. It is the California, which is to be built at the Brooklyn Navy Yard at a cost of $7,000,000. It will also be the largest battleship yet built for our navy—624 feet long and 97 feet wide, with a displacement of 32,000 tons and a speed of 21 knots.

Its main battery will be 12-inch guns. It will have a torpedo defense battery, which the European war has shown to be of great importance. This battery will have 22 5-inch guns.

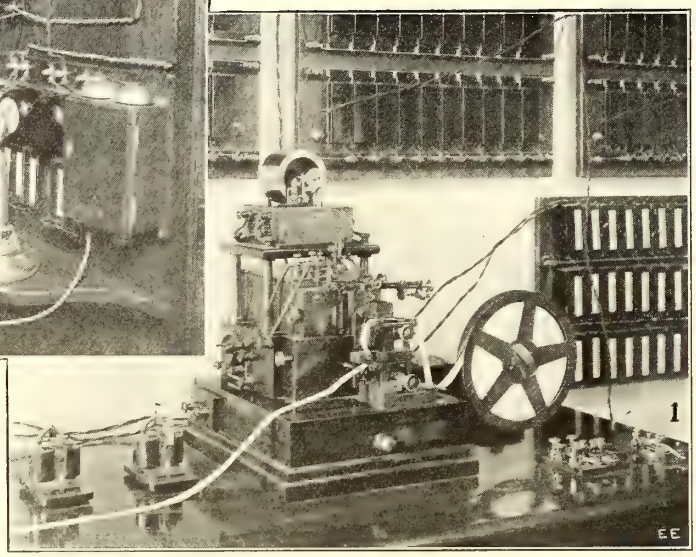
Inventors have long dreamed of an electric battleship. With the California this will be realized and with it we lead the world, just as we led it by the device of "central fire"—that is, having the heavy guns over the keel instead of at the sides—a device that the new European battleships have copied.

In the California there will be no directly connected turbines. The power will be transmitted to the four screw propellers through slow-speed motors which will relieve much of the strain on the crank shaft. The electric power installation will consist of two separate plants, each furnishing power for two screws. If desirable the ship can be operated on one generator. Electricity provides the smoothest and most flexible method known of propelling, steering and operating a ship.



WEATHER BY INTER-CITY WIRELESS.

Advices received recently from Cincinnati stated that weather bureaus of that city and Pittsburgh would soon exchange information by wireless. The announcement was reported to have been made by Weather Forecaster W. C. Devereau, of Cincinnati, that preliminary arrangements for the installation of the service were made at a conference between Mr. Devereau and Henry M. Rubel, Jr., who is installing a station at Cincinnati. Mr. Rubel is said to be connected with the Marconi company, and proposes to erect powerful plants at Pittsburgh, Louisville, Evansville, Huntington, Cairo and other cities, and to co-operate with the weather bureau in each city in disseminating weather and river information. The stations are expected to be ready for operation by fall.



To analyze the unburned gases given off by industrial plants a French scientist has invented electrical apparatus which makes the tests and records the results automatically.

Long Distance Submarine Telegraphy and Telephony

HOW would you like to speak to your friend in Cairo, Paris or Liverpool from your office or home by simply removing the receiver, get central to connect you and then hear your friend's "Hello" over the wire? This may soon be a realization, as the inventions of Dr. Guiseppe Musso tend to prove.

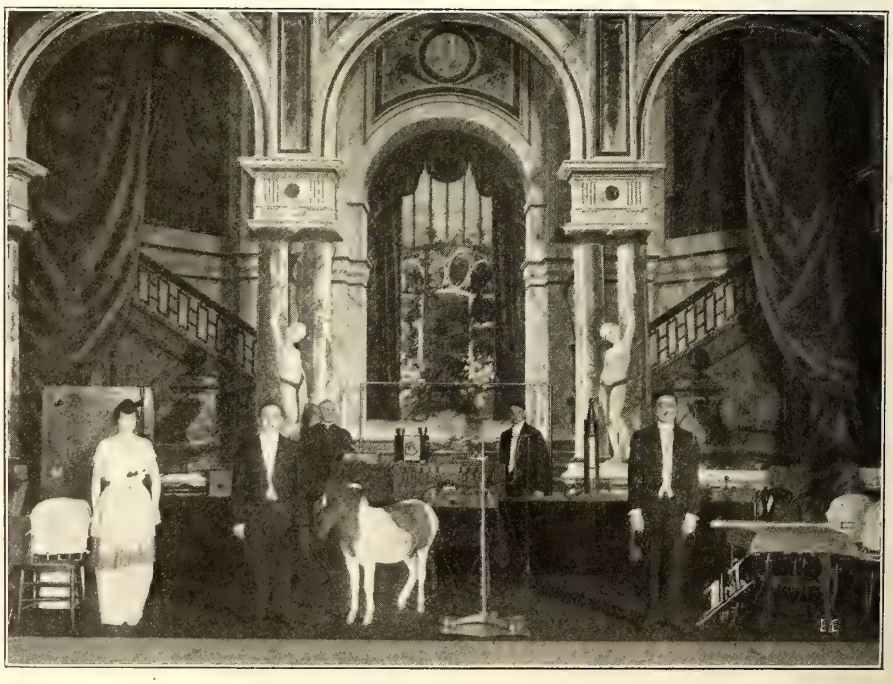
Below (Fig. 1) Portrays Dr. Musso's Highly Perfected Long Distance Telegraphic Recorder, Which Prints the Dots and Dashes on a Moving Paper Strip.

Above (Fig. 2) Illustrates the Small Difference Between Dr. Musso's (at left) New Submarine Cable Telephone Set and Ordinary Telephone (at right).

Many telegraph and telephone engineers are only too well aware of the difficulties encountered in the submarine cables, such as enormous inherent capacities, resistances, etc. Some companies have even gone to the extent of developing a new cable with which to reduce the large amount of capacity, and thousands of dollars have been expended in this direction, but very little headway has been made. The longest talking distance ever covered with a submarine cable was 31 miles. Also the incoming speech waves were so indistinct that it was practically impossible to reproduce articulate conversation.

However, with this latest invention of the Italian scientist, the Government has recognized that greater distances can be covered and has tested the apparatus with an actual submarine cable in Alaska, which carried successfully speech over a distance of 320 nautical miles. Arrangements are now being made for greater experimentation along this line, and distances up to 3,000 miles have actually been covered with an artificial line, as partly illustrated in Fig. 1. This consists of lumped inductances and capacities mounted on the wall.

The various condensers on the wall represent the capacity of the usual cable. By changing the circuits various artificial cable lines can be obtained. Fig. 2 shows the difference between the present telephone (at the right) and Dr. Musso's long distance submarine cable telephones. No additional apparata is required, with the exception of those illustrated here.



Dr. Musso has also turned his inventive brain to the development of a high speed submarine cable telegraph apparatus. The receiving apparatus of the recording type is shown at Fig. 2 on the table in the foreground. Messages can be recorded with much greater rapidity than that with which the human hand is capable of writing; the signals being automatically notated on a strip of paper, as perceived.

ELECTRIC PONY SHOOTS SPARKS

Many spectacular adaptations have been made for several years past of high frequency electric currents on the theatrical stage, with great success. But the ever active, quick-witted minds of theatrical performers have now discovered a new scheme for attracting and holding the interest of the public in the application of these high frequency currents to animals. At first it appeared as if this new idea would never be successfully produced, as in many cases the animal would become electrocuted by the current, or the shock would prove sufficient to make the animal uncontrollable.

However, after long, persistent practise and training Mr. La Reine has succeeded in applying these high voltage currents to a pony which is now able to withstand the shocks without any outward or visible sign of emotion.

The illustration herewith portrays Mr. La Reine and his pony performing a stage act known as "The Electric Pony." The animal is charged with high voltage electricity, produced by a Tesla coil, and various interesting electrical feats are enacted, such as drawing sparks, lighting paper from any part of its body, and many others. The act is intensely interesting to the audience and the effect very spectacular.

The Pony That Shoots Forth Electric Sparks for the Amusement of Theater Audiences.

BLIND WIRELESS OPERATOR.

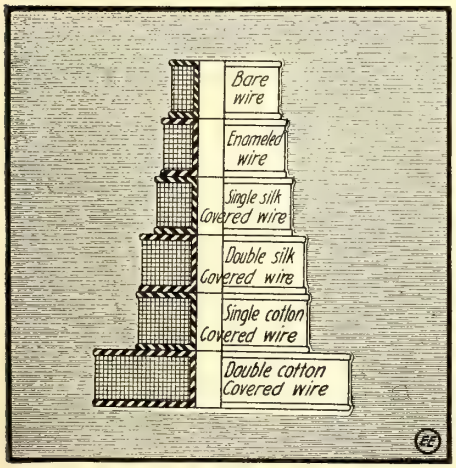
J. William Ellis, of Lakewood, said to be the only blind wireless operator in the world, opened a wireless telegraph station at Rocky Point, R. I., recently for exhibition and transmitting purposes. The antennae extends from the Rocky Point tower to the cupola of the hotel, the station being in the tower.

All kinds of commercial and naval messages were received, including those from outgoing and incoming steamers all over the coast from Canada to Guantanamo Bay, Cuba. Visitors are invited to the station to watch Mr. Ellis operate.

Mr. Ellis has been engaged in the wireless operating business for 10 years, for the last eight years as builder and manufacturer of all kinds of receiving and sending wireless apparatus. He was a commercial operator eight years ago at the Waldorf-Astoria Hotel in New York, and has also operated for the New York Association for the Blind and the Metropolitan Opera House. He has also controlled and operated a large receiving station at Lakewood.

Wireless apparatus that weighs but eight pounds yet will transmit messages 21 miles and has received signals more than 300 miles has been invented by a New Jersey man.

Enameled Magnet Wire, Its Properties and Manufacture



By L. Earl Deane

THE older readers of this article will probably remember that in Franklin's time electricity was not considered as it is now, nor did the Philadelphian have the modern conveniences with which to conduct his experiments. Annunciator wire was not used to conduct the current to the key, nor was a toy motor, such as a Knapp or Loomis, used to wind in the kite. One is caused to wonder, when he stops to think of the marvelous advance within so short a time, in every phase of electrical progress.

Electricity in the time of Franklin was considered an uncontrollable atmospheric discharge. Later it was found to have been wrongly considered and was called a fluid, because it apparently flowed, as did water, through certain mediums. Now we think that we have it boiled down to a vibratory motion of the molecules or etheric electrons.

Knowing that electricity traveled with varying degrees of strength and velocity through different mediums, it became necessary to "insulate" the conductors, to interpose some substance between the conductor and other conductors, so as to prevent "leaks." Such a substance was said to possess a "dielectric" quality. Silk and cotton, being found low in the scale of conductors, came into universal use. Coils were wound for individual use, no attention being given to another's problems.

It was known that certain laws existed concerning fixed relations between the number of turns on a coil, size of wire used, resistance of winding, current consumption and work to be performed. It was also known that these relations varied with the thickness of *insulation*. The problem then was to get at the basic principles, formulate them, and arrive at some standardized results which would prove of practical value. Engineers became interested. The old forms of insulation were unsatisfactory for several reasons: They occupied too much space; broke down under moderately high voltage; would not withstand high temperatures; absorbed moisture; and disintegrated under the action of acids.

Showing Relative Volume of Various Kinds of Insulated Magnet Wire. Note Small Space Occupied by the Enameled Wire.

Thus you see the great problem which the inventors and experimenters in industrial chemistry had to attack. A covering was to be found which would occupy less space than does a single silk thread. High tension currents must be carried safely. It must withstand heat, both external and internal. It must be impervious to moisture and inert to chemical action. It is not necessary, if I could indeed do so, to relate all the difficulties encountered. Suffice it to say, the first producers of enamel wire placed on the market a form of insulation —an enamel—which met all these requirements and was also elastic enough to be practicable.

As to the voltage test on such enameled wire, I will give the result of a recent experiment performed by Prof. A. B. Smith, of Purdue University. A three-foot length of No. 36 B. & S. wire stood the following voltage tests before puncturing:

Enamel, 736 volts; single cotton covered, 587 volts; single silk covered, 527 volts. Thus you see the advantage of enamel over fabric covers as to danger of electrical breakdowns.

As to the space occupied the following tables show the great saving in enamel over the older insulations, as to number of feet per pound and outside diameters of various covers.

WIRE, APPROXIMATE FT. PER LB.

B. & S. gauge.	Single cotton.	Single silk.	Enamel.	Bare wire
24	763	799	810	818
27	1,500	1,584	1,620	1,639
30	2,860	3,148	3,240	3,287
32	4,234	4,913	5,132	5,227
35	7,755	9,536	10,197	10,480
40	18,376	26,558	32,107	33,410

OUTSIDE DIAMETERS.

B. & S. gauge.	Single cotton.	Single silk.	Enamel.	Bare wire
14	.0686	.0661	.0660	.0641
20	.0365	.0340	.0333	.0320
27	.0182	.0162	.0152	.0142
35	.0096	.0076	.0061	.0056
40	.0071	.0051	.0034	.0031

The above tables show enameled wire to be in close proximity to bare wire. The importance of this is best shown by the law of comparative activity: *The activity of a coil winding varies directly as the ratio between the cross sectional area of the conductor and that of the conductor plus the insulation.* To make it plain, the closer the winding lies to the core the greater the strength of the magnetic field, and enameled wire brings the turns closer to the core because the insulation is thinner.

Enamel is guaranteed to withstand a temperature of 500° F. provided the coil is allowed to cool before being moved. I have seen cases where the test was much more severe than this, but a conservative guarantee is 500°.

Internal heat, whether by normal or abnormal currents, is diffused by enamel, so that the proper working temperature of the coil is more easily obtained and maintained.

Enamel is not affected by moisture, water, oils or greases, nor is it injured by chemical action. Gases and fumes, so often encountered, do not injure enamel.

Mechanical strength, twists, turns, etc., may best be proved by actual test. Enamel will stand far more abuse than will fabric covers. It may be stretched without opening the insulation, as will fabric.

The combination covers, cotton or silk wound over enamel, afford the same advantages as enamel, with the additional protection for voltage or to serve as a cushion in cases where it is necessary because of mechanical difficulties, friction, abrasion, jarring, etc.

Fig. 1 (at left) Shows Machinery Used in the Manufacture of Enameled Magnet Wire. Fig. 2 (above) Illustrates Part of the Finishing, Winding and Inspecting Department.

With the fact that less wire in weight, in enamel stock, is required than in fabric covers; that it costs less by the pound than any fabric; and that there are more feet to the pound than in the fabrics, the greater saving is evident.

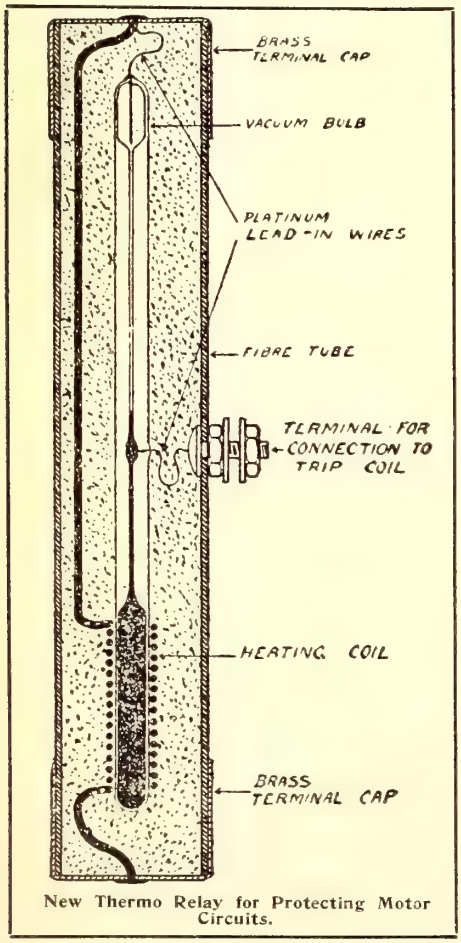
The process of manufacture is depicted partly by Fig. 1. This shows the process as used by the American Enameled Wire Co. The bare wire runs from the spools, S (there is a table, T, on each side of the oven, so that twenty wires run through each machine, ten on a side), over the pulleys, P, through the enamel tank, E, which is heated by an electric heater. From there it runs vertically through the oven, O, where it is baked at the proper temperature. Gears, F, drive fans to keep the temperature even throughout the oven. Each machine is also connected to a blower pipe, which serves as an additional equalizer of oven temperature. This process is repeated five times, five coats on a wire, even down to No. 40, which measures .0034 inch outside diameter. Each coat is baked hard separately before the next coat is applied. The finished wire runs off on to spools at W.

From the enameling room the wire goes to the inspection room, Fig. 2. Here every inch of wire is inspected by experts before it leaves the plant. Any defective spots are cut out and the wire is welded and enameled at the weld, leaving no joint or large place. The weld is not weakened and cannot be detected from any part of the wire.

Despite the most careful precaution in enameling some defective wire gets through to the inspectors. The power plant is governed so as to keep a uniform speed on the machines. Machine shafts are con-

trolled for the same purpose. All working rooms are kept at a constant temperature. The machines are "boosted," so that even the very fine sizes of wires are not stretched in running through as many times as they do. Pin holes, burnt or raw enamel, rough spots, lack of uniformity in size, etc., must be noted and detected by the inspectors. Wire must measure to size or it is rejected. The finest possible instruments are used for this, measuring directly to .0001 inch.

From inspection it is sent to the main shipping room, where it is boxed and sent to all parts of the world.



Just another point before quitting the issue—do not hesitate to ask the manufacturers for information. Some one often asks me how to clean the wire for terminals, etc. The maker of the wire which you use can give you a tip on this that will be worth asking for. Suggestions as to binders, etc., are sometimes desirable. Do not be afraid to ask what you want to know. In all probability the engineers of the wire company can help you, and if not they will be willing to tell you so and no harm will be done by communicating with them.

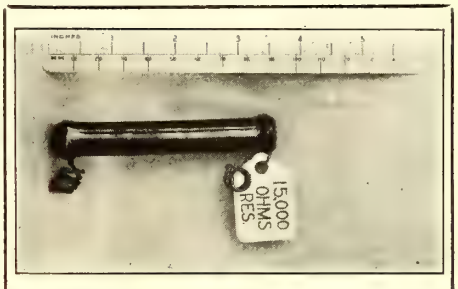
NEW THERMO-RELAY FOR MOTOR PROTECTION.

A very ingenious and undoubtedly efficient electric motor protector, similar in size to the usual cartridge fuse, with which we are all familiar more or less, is shown in the sectional view here depicted.

The principle of this device, known as the "Thermo-Relay," is based upon the fact that if a small coil of wire, forming a heating coil as our illustration shows, is placed around the base of a glass tube, similar to a thermometer tube and which contains some mercury, then when a certain current passes through the circuit (and consequently through the heating coil which is in series with the main motor leads) the mercury will gradually rise. Now when a certain predetermined amount of amperes passes through this device, the mercury will rise high enough in the tube to close a trip coil circuit through the binding post in the side of the tube, as indicated.



New Thermo Relay for Protecting Motor Circuits.

The trip coil acts the same as a circuit breaker coil, of course, and opens the switch, thereby cutting off the current supply to the motor. This device evidently is extremely practical and sturdy in its operation, as the manufacturers of the same offer $100 to anyone who can burn out a motor properly protected by the use of these Thermo-Relays in the main circuit.

NEW COMPACT RESISTANCE UNIT.

Herewith is a photograph which shows a new and extremely compact resistance unit 7/16 inch in diameter by 3½ inches long.

This resistance unit has 15,000 ohms of resistance on one layer of wire. The wire is so fine that it would be crumpled up in two or three days if left open to the atmosphere with no current passing through it, but it is covered with a vitreous enamel insulation which protects it from the oxidizing influence of the atmosphere, causing it to last an unlimited length of time.

Smallest "High Value" Resistance Made.

This tube is interesting. It is a porcelain tube with wire wound upon it and covered with a vitreous enamel which entirely encloses it and protects it from chemical, mechanical and electrical deterioration. It is doubtful if a unit of half this resistance, or even a third of this resistance, has ever been produced, in this space, on a single layer of wire, up to a short time ago.

POWERFUL NEW CHINESE RADIO PLANT.

Arrangements have been completed for the erection of a wireless installation at Foochow at a cost of $15,000. The plant is to be of the Telefunken style, with an A. E. G. (German) dynamo of 12 kilowatts, converter and a gas engine of 28 horsepower. The storage batteries will be charged from the dynamo; the converter, being operated by the storage batteries, will make an oscillating current of 500 cycles. Two wooden masts are to be erected, each 200 feet high. The guaranteed range is 1,500 miles at night and 650 miles in the daytime, although it will be possible to secure a range of 2,000 miles and 1,000 miles, respectively.

The wireless station will be operated in connection with and under the control of the Chinese Government telegraphs and will be devoted chiefly to military use. Public messages will, however, be sent and received to and from ships and the wireless stations already erected at Shanghai, Canton and Wuchang. Wireless plants have now been erected or are in process of construction at Shanghai, Canton, Peking, Kalgan, Wuchang and Foochow. Four more stations are to be installed, two of which will probably be at Yunnanfu and Chengtu.

ELECTRIC ILLUSION SIGN FOR BARBERS.

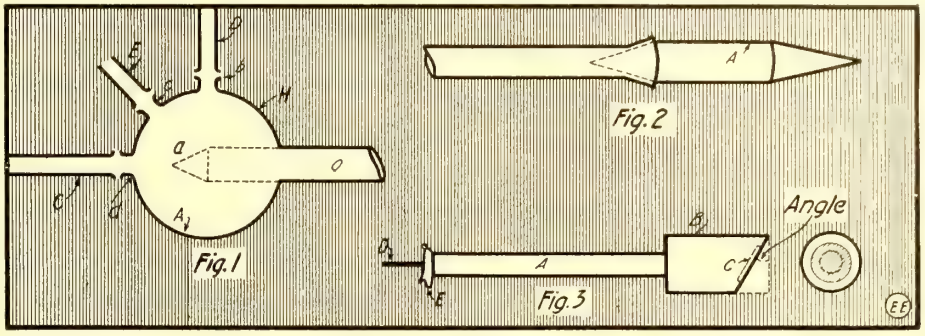
A very attractive electric illusion sign was recently perfected and put in operation for a New York barber. The sign herewith illustrated consists of a circular disc of glass and having three colors; red, white and blue painted on it, as shown.

Novel Electric Illusion Barber Sign.

This disc is rotated at medium speed by a small electric motor connected to the shaft of the disc by means of a leather belt. When in operation various novel effects are produced by the constantly changing colors, which never fail to attract the eye of the passer-by. This sign is one of the well-known Federal line.

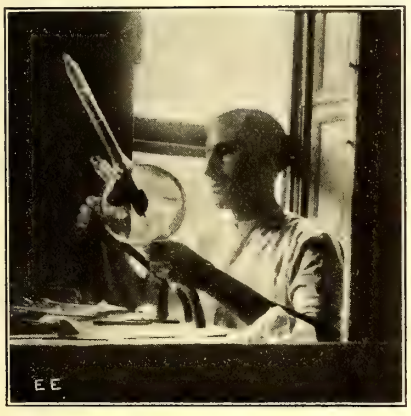
IONOMAGNETIC ROTATION.

A. Righi finds that a body turning lightly on an axis and placed inside a gas suitably diluted and ionized (for instance, by means of sparks) will commence to rotate around its axis as soon as a magnetic field is created in the direction of the axis. This phenomenon the author has called ionomagnetic rotation. He explains it as follows: It is known that the path of an electrically charged particle (ion or electron) changes when a magnetic field commences to act, and when this field is uniform the path becomes a helix with its axis parallel to the field. The sense in which this curve is followed is identical with the sense of the current flowing in the coil producing the field when there are negative ions or electrons; the sense is the opposite when there are positive ions. So when there exists a magnetic field the ions and the electrons will follow helical areas instead of straight paths.



Owing to the action of the magnetic field they will be directed all in the same sense and all around the body, thus producing the rotation of the latter. This will occur in the same sense as the current producing the field in the case of positive ions, and in the contrary sense in the case of negative ions. As the couple changes sign with change in sign of the electric particles, the ionomagnetic rotations will be generally produced by the difference of two couples of contrary signs. At the beginning of these researches the author was for long in doubt whether the rotations observed could be explained by the actions of the ordinary electromagnetic forces. Finally he has been led to conceive that the well-known forces which provoke the movement of a conductor through which an electric current is passing, when other currents or a magnetic field are acting, are the result of the shocks of the electrons which, according to modern theories, move in the interior of the conductor and constitutes the current.—Abstract from *Atti Asso. Elet-Italiana* in *The Electrician*, London.

X-Ray Tubes and Their Manufacture



By Samuel Cohen

IT was not until after the discovery of the phenomena of the X-rays by Wilhelm Konrad Röntgen that the world realized the value of these powerful penetrative rays. Many articles have been written on the theory of X-ray tubes, but none of these tell how the tubes are made. It is the intention of this short article to show the reader how these tubes are manufactured.

One of the first operations consists of blowing out the bulb A, Fig. 1. This is done by closing a glass tube O at point (a) and heating it to redness. When the operator sees that the glass is heated to the right temperature he then slowly and carefully blows into the open end of the tube, which expands the hot soft portion of the tube at (a), and by blowing constantly and turning the tube in the flame the bulb A is formed. After the bulb is blown to the proper size the holes b, c, d are next made. This is done by heating the glass at the indicated points with a sharp blow flame and then blowing into the neck, which forces the soft heated parts out. A small projection is made on the holes as shown; the purpose of these projections will be seen later. All the blowing of the glass is done by the operator, and no compressed air is utilized.

Various Stages in Manufacture of X-Ray Tubes.

Expert Glass Blowers Are Employed Only in Making the X-Ray Tubes.

The electrode glass tubes are next made. They consist of a glass tube of proper dimensions, and on one end of these tubes a small flared portion is made. This is done by heating one end in a flame and introducing a conical piece of charcoal, as shown in A, Fig. 2. The projection of the hole in the glass bulb and the flared end of the electrode glass tubes (c, Fig. 1) are now welded together; they are heated simultaneously in a brush flame, that is, a pointed flame, and jointed while quite soft. The joint is made true and even by constantly turning the tube to keep the glass evenly heated. All the electrode tubes are welded in the same manner.

One of the electrodes consists of a tungsten alloy disc C, Fig. 3, welded in a solid copper rod B. A cylindrical iron tube A is used for supporting the target C and copper rod B. Extreme care is taken in making the proper angle on the copper rod as shown. The deflection of the X-rays depend wholly upon this angle of the tungsten target. A short piece of platinum wire D is next welded to the iron cylinder A. A small quantity of soft glass E is now poured on the end of the cylinder. The electrodes G and F (Fig. 4) are made in the same way, but consist only of aluminum discs instead of the tungsten.

The next process is to weld the electrodes to the tubes C, D, E, Fig. 1. The electrode is placed inside of the tube, and the end of the glass tube is heated to redness. It is now closed and a small hole is made by forcing a piece of glass through the soft portion. The platinum wire is now passed through this hole and the end is again heated. The glass on the end of the electrode E, Fig. 3, welds together with the end of the glass tube and it is thus sealed up. The weld is made smooth and true by constantly turning the end in a flame and blowing through end H (Fig. 4) until the end is perfectly sealed. The other electrodes are sealed in the same way.

The tube is now ready to be exhausted. This is accomplished by connecting the small open tube H, Fig. 4, to an exhaust or vacuum pump, which may be a mercury, oil or molecular exhaust pump. After proper vacuum is obtained the glass tube H is sealed, while the pump is exhausting the tube. This is done in order to prevent any air entering the bulb. Names and trade-marks on these tubes are made by the etching or sand blast process. The location where the name is to be etched is inserted in a solution of boiled common wax and allowed to dry. The name is next marked out in the wax and then dipped into hydrofluoric acid, which dissolves glass. The etching continues for a few minutes and then the tube is rinsed in clear water. The wax is now removed, allowing the neatly etched letters to remain.

The main difficulty in the manufacture of X-ray tubes is in the glass work, and therefore expert glass blowers are required. The day will come, perhaps, when someone will invent a machine for blowing glass bulbs automatically, which will reduce enormously the price of X-ray tubes.

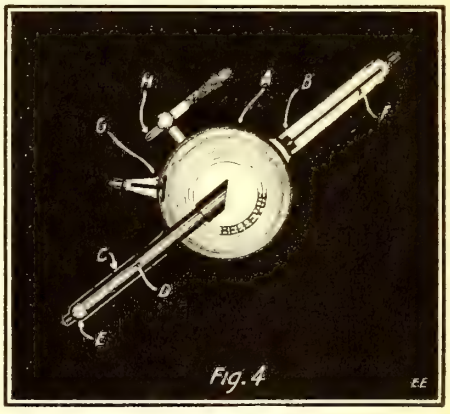


Fig. 4. Showing the Different Parts of X-Ray Tube Assembled.

At present all the work in making X-ray tubes may be said to be hand work and thus the expense is severely high.

A BATTERY TYPE MAGNETIZER.

By Frank C. Perkins.

The accompanying illustration shows an effective battery type magnetizer of the Swedish-American type developed at Chicago, Ill. It is pointed out that magnets should always be kept fully charged. All magnets lose their strength in time, and this results in decreased efficiency of whatever device they are used on. This holds true of telephone apparatus, automobile, motorcycle and motor boat magnetos, charging and lighting generators.

In telephone apparatus weak generators, receivers or ringer magnets will render satisfactory service impossible, and in magnetos for gas or gasoline engines a fully charged magneto with "saturated" magnets gives a much fatter, hotter spark than one whose efficiency is lowered by weak magnets.

New Portable Type Magnetizer for Recharging Magnets.

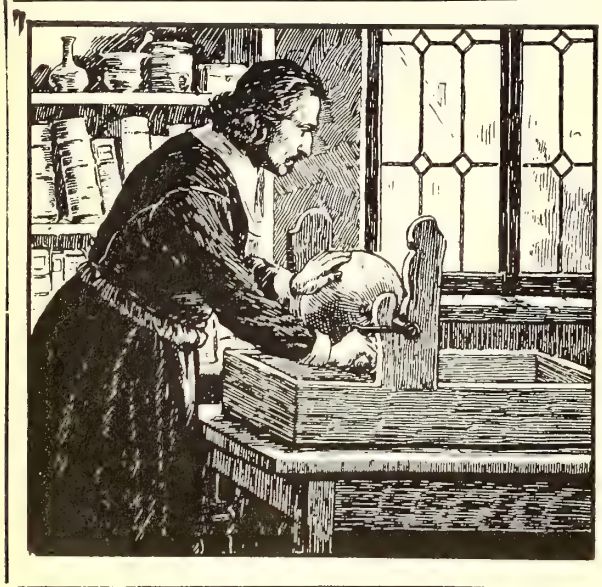
It is recognized that sending of the magnets to the manufacturer to be remagnetized causes long delays and considerable expense, and they are often demagnetized or broken in transportation. These difficulties can be eliminated by using a magnetizer of the type illustrated in the accompanying photograph, which is efficient, durable, compact, sturdy and easy to operate. It requires no experience to "charge" magnets, and it will operate on five ordinary dry cells or a 6-volt storage battery or on 110-volt direct-current lighting circuit.

It is quickly adjustable to any size or shape of magnet. It is equipped with a switch which automatically cuts off the current. Less than half a minute is required to fully energize or "remagnetize" any magnet. Thus this device saves both time and money.

The Static Machine, Past and Present

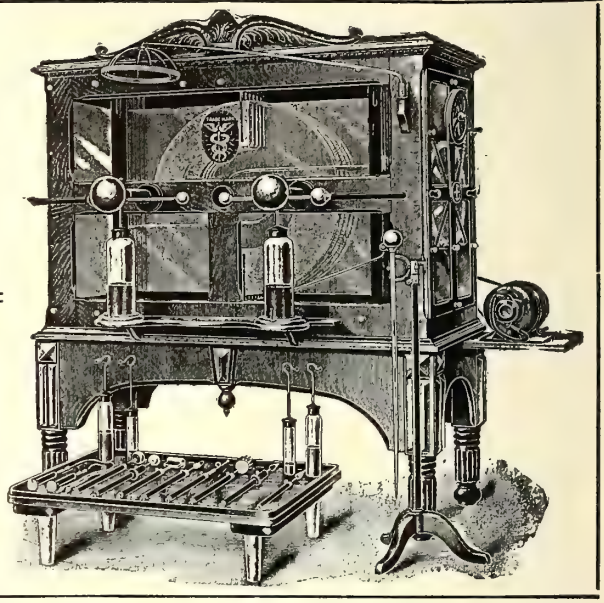
THE large static machines, or for that matter even the smaller ones in use to-day, are quite efficient indeed and a wonderful improvement over the first attempts made in producing static electricity.

The earliest form of electrical generating machine of the static type was that devised by Otto Von Guericke, of Magdeburg, Germany, in the year 1630. His machine consisted of a globe of sulphur fixed upon a rotatable spindle, so that it could be turned around rapidly by means of a crank, and static shocks were obtained from this crude device by pressing against the surface of the sulphur ball with the hand while it was being turned.



With this simple arrangement Von Guericke discovered the existence of small electric sparks and the peculiarity of static electric charges. This sulphur ball machine and Von Guericke himself are seen in illustration at Fig. 1, while Fig. 2 shows some of the experiments being made with this crude static generator. The boy hanging over presses against the sulphur ball with his feet and transfers the static electricity to the young lady by means of his hands as depicted. Note the electric attraction of the small bits of paper from the table on the extreme left.

Later Sir Isaac Newton, of England, replaced the sulphur ball utilized in Von Guericke's machine by a globe of glass. At a later period the general form of the machine was improved from time to time by several German electricians, notably Von Bose, who added a collector or "prime conductor" in the shape of an iron tube, held by a person standing on cakes of rosin to insulate him from the ground, or else the collector was suspended by silken threads. Also Winckler, of Leipzig, substituted a leather cushion for the hand as a rubber, and Gordon, of Erfurth, rendered the static machine more easy of construction by making use of a glass cylinder instead of a glass globe. The electricity in this case was led from the excited cylinder or globe to the prime conductor by a metallic chain, which hung over the globe. A pointed collector was not employed until after Franklin's famous researches on the action of points with respect to electric charges.



About the year 1760 De La Fond, Planta, Ramsden and Cuthbertson developed machines using flat glass plates instead of glass cylinders. Fig. 3 shows a static machine built by Martinus van Marum, in 1785, utilizing the glass plate principle. The machine consisted of two glass plates 23 inches in diameter and 7½ inches apart. The sectors were 15½ inches in diameter and were made of sheet copper. The glass standards were 57 inches high. When this generator was in operation it only developed a thin spark 8 inches long and a brush discharge in the dark of 21 inches. The two plates were operated by means of a large crank shown at the extreme left and designed for two men.

From that time on the principal modifications and improvements in the static machine have been along the line of the substitution of ebonite or hard rubber, and in some cases patented compound mixtures instead of glass for the rotating plates have been employed. Further improvements have been made in the invention of compound machines, depending upon the principles of induction and convection.

A modern type of static machine capable of giving steady and powerful sparks 20

At Left, Fig. 1, Is Seen Otto Von Guericke, the Earliest Worker in the Field of Static Electrical Machines and Also His First Crude "Sulphur Ball" Static Generator Made in the Year 1630.

At Right, Fig. 4, Illustrating the Latest Model Multiple Glass Plate Static Machine, with Driving Motor. It Will Develop Heavy Sparks 20 Inches Long of Great Electrotherapeutical Value.

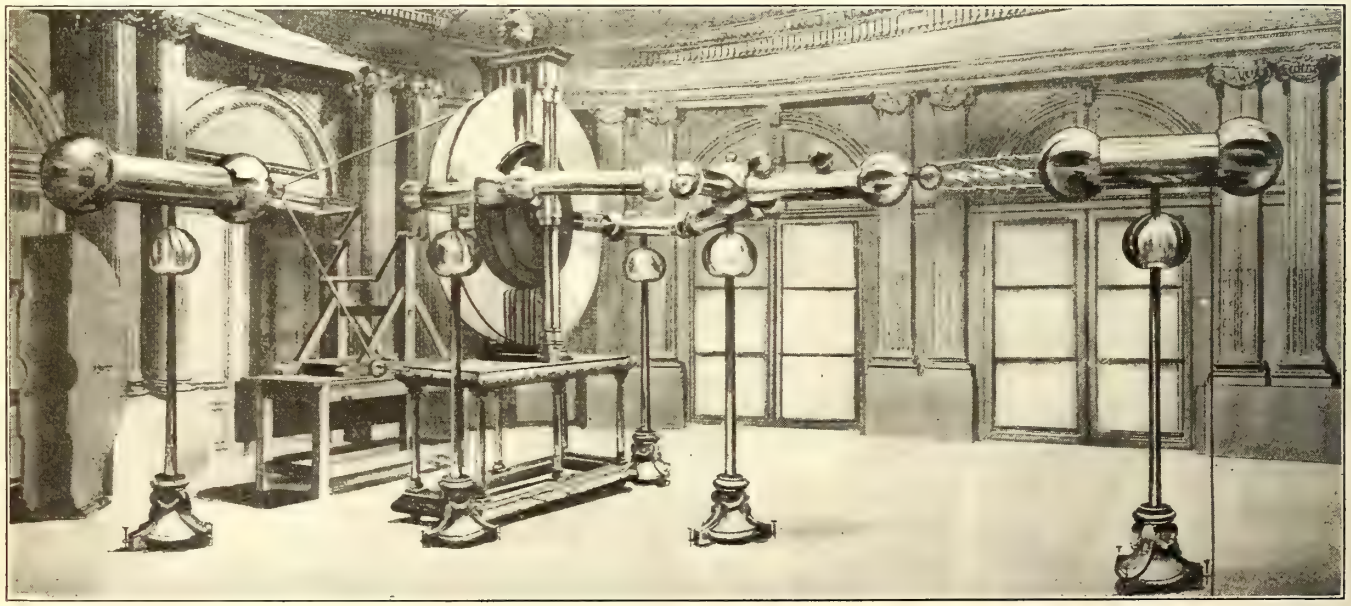


Fig. 3. This Portrays an Early Static Machine of Massive Proportions, Built in 1785 by Martinus Van Marum. This Ponderous Machine Standing 10 Feet High, Produced But 8-inch Sparks.

inches long is shown in Fig. 4. This machine has a multiplicity of large rotating plates, and also makes use of Leyden jar condensers to increase the activity or volume of the discharge between the smaller brass balls observed on the side of the machine. This powerful instrument is driven by an electric motor and is much used for physicians' requirements. A complete set of various electrodes for treatment work is shown on the insulated glass foot stand. The static machine is of low over-all efficiency and is being rapidly substituted by modern high-voltage transformers and spark coils.

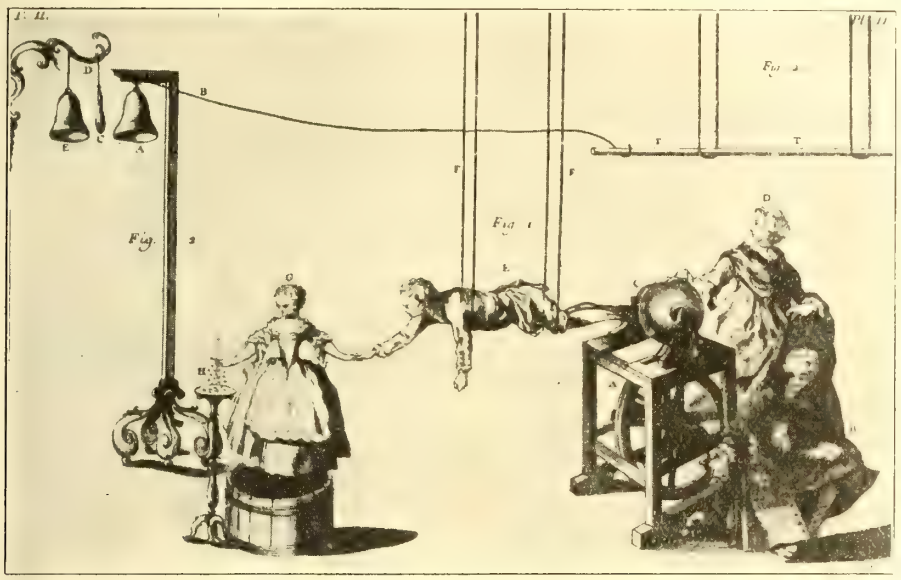

Fig. 2. Experiments with the Early Static Electric Generators Were Mostly Carried Out With a "Human" Prime Conductor as Here Shown.

OZONIZER HELPS FISH CANNERIES OF EUROPE.

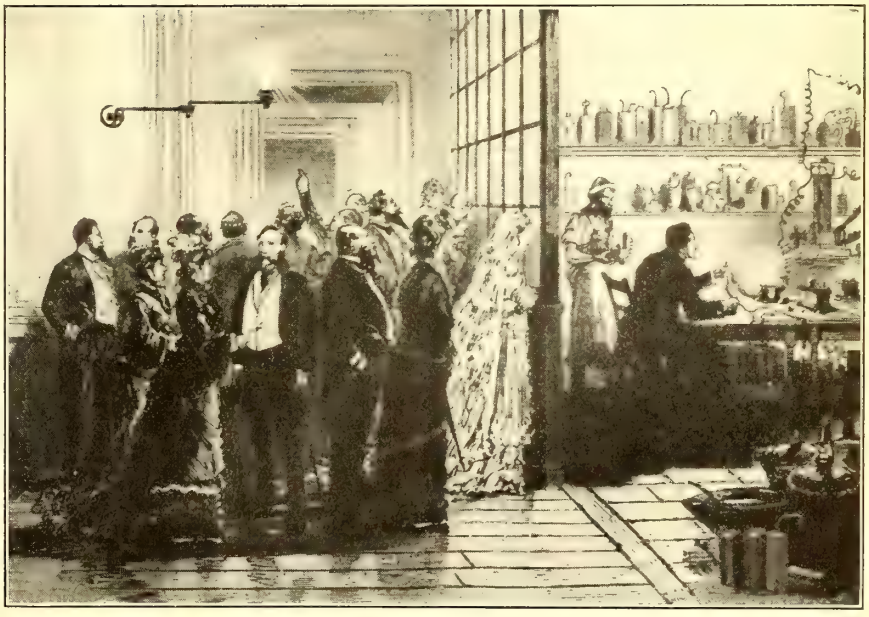
New uses for electricity are being discovered every day. Even in war-swept Europe ways and means are being devised whereby electricity is employed to lighten labor and to improve working and living conditions. One of the latest and most novel applications is the use of Westinghouse electric ozonizers to reduce the odors usually prevalent in the fish canneries of Norway and Sweden, which, as is well known, supply a large part of the world's needs and form one of the chief industries of those countries.

Several months ago 50 of these devices were installed in the canning factories that line the coasts of Norway and Sweden, and their success was so marked that orders were immediately placed for approximately 130 additional ones, which will soon be in operation.

An ozonizer is a device that converts part of the oxygen in the air into ozone, which is nothing more than a modification of oxygen, having increased chemical activity. It has properties similar to those of oxygen, but to a more marked degree. It is a strong oxydizing agent, and, therefore, attacks organic material, such as germs, bacteria and the small organic particles that produce odors. It is this property of being able to destroy odors that has made the ozonizer so popular in the canning factories, and it is claimed that, while its use does not entirely eliminate the strong odors attending this work, it reduces them so they are not objectionable. By doing this it greatly improves working conditions, making them more pleasant and more sanitary.

Ozone is produced naturally by lightning discharges, by the slight electric effect produced by the separation of particles of spray from waves and waterfalls, and by some other of nature's processes. The manner in which it is produced electrically is interesting. A current at high voltage is applied to the inside and outside coatings of specially prepared glass cylinders and minute brush discharges take place over the inner surface. These tiny discharges act on the air in the cylinder or tube and change part of the oxygen in the air into ozone.

WHEN EDISON GOT MARRIED.



Although it is a fact not generally known, Thomas A. Edison, the master inventor, was so engrossed in his electrical researches at the time of his marriage in 1873 to Miss Mary Stillwell, that at the appointed hour when the minister was to pronounce the ceremony, the guests were unable to find Mr. Edison for some time.

Finally he was located in his private laboratory, experimenting with the electric light, which was in those days, of course, a great novelty, and, in fact, a brand new branch of science.

Our illustration herewith reproduced from an old print shows this episode in Edison's life and follows in many ways a number of other incidents which have occurred during his strenuous career.

It is recorded that at one time he had presented to him a box of "Havana" cigars, and although they were of doubtful quality he in a very short time had smoked the whole box of them. Absent mindedness such as this is an attribute of the greatest scientists of the world. When walking about his extensive laboratories at West Orange, N. J., it is rarely that Mr. Edison notices anyone, whether they are callers or not, and he walks by even when close enough to brush their clothes with his coat. He does not recognize them even though they are old-time friends, as he is so intensely absorbed in thought over some invention or other.

Mr. Edison's wife has undoubtedly helped in a myriad of ways to make him the master inventor and scientist that he is to-day.

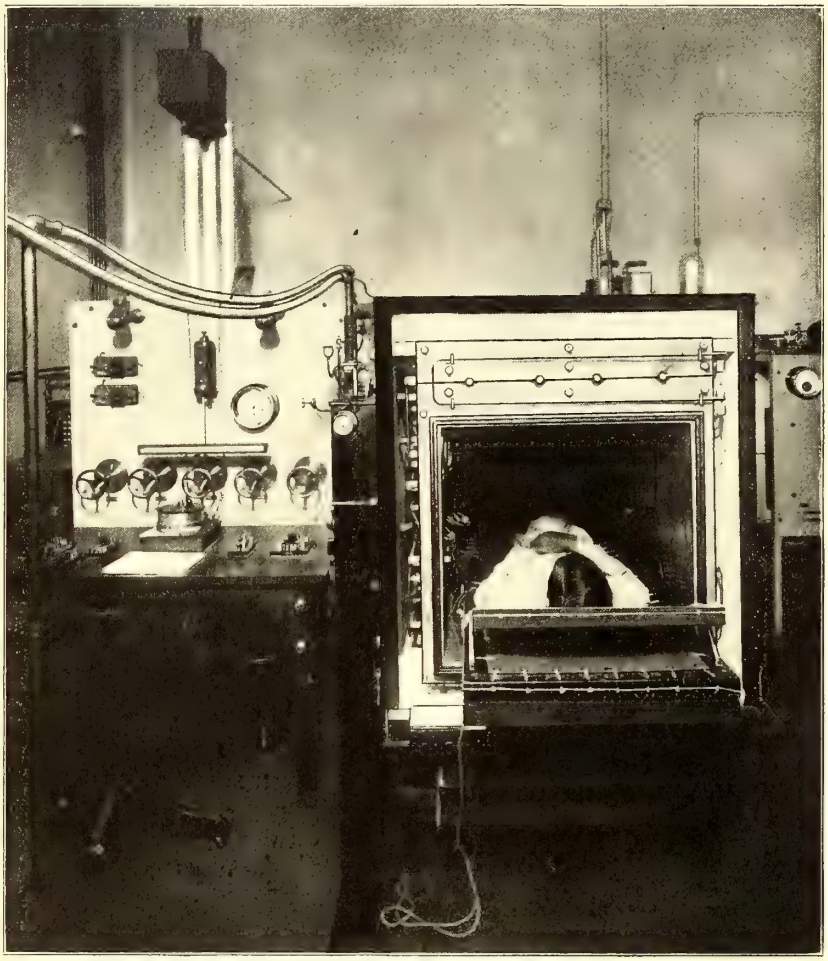
How Edison Was Married.

THIS MODEST INVENTOR WOULD STOP WORLD WAR.

"I can make the United States the strongest nation in the world. I can end the European struggle in a short time. I can make the smallest nation most powerful."

This is the assertion of John Vogelzangs, of Menominee, Mich., an inventor, who claims to have a method of extracting electricity from the air so that aircraft might be manned with powerful guns and not be forced to land until they want to.

"I can sweep the seas clear of vessels. I can kill armies and level cities," claimed the inventor, who in the same breath asserted he favored universal peace, but that the world was not ready for it.



He says Secretary Daniels' plan for an advisory board is good. He refused to give out much information about his new device, and said he lacked money to carry on the work and displayed a letter from Mr. Daniels, written before the war broke out, saying this nation was not ready to take up his ideas.

Vogelzangs has a reputation for being an inventor of ability. He made a street cleaner which he refused to sell for $10,000.

New Calorimeter Registers Energy of Man's Every Move

A respiration calorimeter is an apparatus designed for the measurement of the gaseous exchange between a living organism and the atmosphere which surrounds it, and the simultaneous measurement of the quantity of heat produced by that organism.

The first contrivance of this nature was described by Lavoisier in 1780. It will be remembered that Lavoisier was the first to comprehend the significance of the then newly discovered oxygen. Primitive though the apparatus was, yet intellectually inspiring was the mind which so early grasped the principles and understood many of the difficulties.

Marvelous New "Human" Calorimeter Which Is So Sensitive in Its Adjustments That the Heat Generated by the Mere Raising of a Man's Arm Indicates on an Instrument.

In our illustration the large opening at the head of the box, into which a man can be slid, measuring 76x70 cm., is closed by two glass plates 7.5 mm. thick, each of them sealed after the subject has entered the calorimeter by means of a mixture of five parts of beeswax and one and a half parts of Venice turpentine. There are numerous pipes and electric cables entering the box for the various control devices, thermopiles, etc.

On the surface of the outer copper wall are attached the wires connecting up the thermopiles. The pipes for cold water are swung on brass angles attached to this surface, and the enameled "Therlo" resistance wire is bound on insulators to the same surface.

It is remarkable how promptly the spirometer (air-pressure gauge) rises when the person within the box makes even a *slight movement* of a hand or leg. In fact, it makes so delicate a movement record that a Porter *work-adder* has been attached in such a manner that the downward movement of a counterpoise weight winds up a thread, and the total amount of thread so wound represents the total work done by the patient during that particular period. By standardizing various movements of the body such as turning over or lifting the arm, it is possible to gain a fairly accurate idea of the amount of muscular movement and express it in centimeters of thread, thus obviating the necessity of printing long, graphic records. So sensitive is this machine that an ordinary telephone is not adaptable for use inside the chamber if a man has to make any movements at all, so a dictagraph with super-sensitive microphone is utilized to convey the subject's speech outside.

The thermopiles between the outer and inner copper walls of the chamber are arranged in three groups, 32 on the top, 30 on the sides and 12 on the bottom, the area covered by each group being warmed by a strand of enameled "Therlo wire," No. 24 B. & S. gauge, whose temperature is controlled by one of the adjustable rheostats.

One thermopile is arranged with one end in the outgoing air current and the other in the ingoing air. The temperature of the latter is adjusted to that of the former by means of a step rheostat and two 55-volt lamps. A similar rheostat controls the temperature of the ingoing water by means of a water-heating resistance.

By carefully controlling the rate of flow and the temperature of the water in the heat absorber it is possible to adapt this calorimeter to wide variations in the heat production of the subjects. For example, on April 23, 1914, an experiment was made on a cretin, with an average heat production of 26 calories an hour. The next day the subject was a patient with exophthalmic goiter, whose heat production averaged 107 calories. In one case the methods of direct and indirect calorimetry agreed within 0.2 per cent. and in the other within 0.7 per cent.

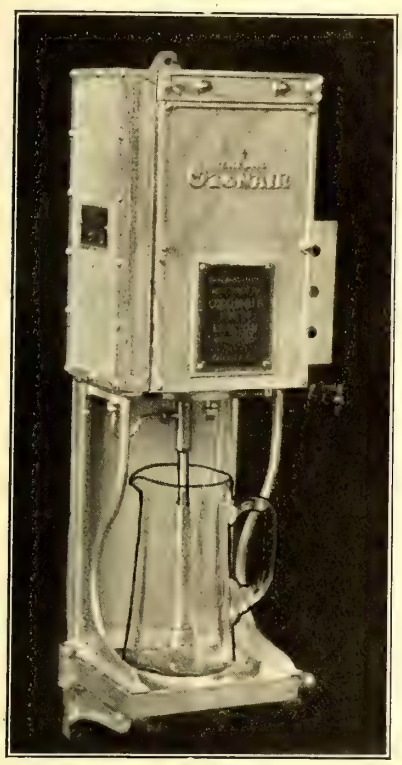
BOOK REVIEW.

"Practical Applied Mathematics," by Jos. W. L. Hale, S.B., E.E. Cloth covers, 206 pages, 185 illustrations. 5x7 inches. Price $1. McGraw-Hill Book Co., New York, N. Y.

A useful handbook on applied shop mathematics starting with the rudiments of arithmetic and leading up to the mensuration of solid and plane surfaces, cube root, practical use of graphic curves, simple binomial equations in algebra, etc. The treatment of each subject is unusually clear, showing in a very practical manner the relation betweeen mathematics and everyday problems, such as locomotive and car weights, strains, etc., tank and other volume calculations, micrometer readings, measurement and relations of angles, circles and spheres. An appendix of very useful tables is added to the book. This book may be recommended to anyone desiring to read up on practical applied mathematics and their adaptation to everyday shop problems.

Radio Stations of the World, compiled by A. Coleman and J. B. Harrietts. 200 pages. 5½x3 inches. Cloth covers. Vest pocket edition, 60 cents. Published by Radio Stations of the World, New York City.

This new radio call book contains in alphabetical order all of the official call signals which are arranged in such form that upon hearing a stations letters one can instantly find the name, nationality, etc., of the station to which that call has been assigned. The names of ship and shore stations are also arranged alphabetically in another section, which also gives the call letters. It also contains the international abbreviations (Q signals). It includes every merchant, government and naval vessel, the high and low power, commercial, government and private land stations of the entire world, both of countries which have and have not agreed to the radio-telegraphic conventions.



It is very handy and is claimed to be the only complete list of international radio stations and calls that has ever been placed upon the market. The book is printed in special clear type, on good quality paper, neatly bound in black cloth, stamped in gold, and fits the vest pocket. It should find a ready sale among all radio operators, both amateur and professional. Supplements are furnished to keep the work up to date. Also blank call pages are inserted to allow of filling in newly assigned calls in their proper relation.

SURGEONS USE ELECTRIC SAW.

Sawing bones by electricity instead of by the old hand method is now all the rage in surgery. It saves labor and makes for accuracy, and soon the suffering public, hearing of the latest, up-to-the-minute methods, will demand that when it must have its skull trepanned or the vertebral tibia sawed off, the job be done according to the latest styles in science.

NEW ENGLISH WATER OZONIZER

One of the most important details relating to the well-being and health of any community must be a pure water supply; pure not only as regards innocuous suspended matter, but free from the germs of such dangerous disease as cholera, typhoid, dysentery, etc. These scourges more often than not are caused by the contamination, accidental or otherwise, of the supply of water at its source or during its passage to the place of distribution.

Improved English Ozone Water Purifier.

Fortunately, there are several methods at hand by means of which these defects can be easily and cheaply remedied.

The simplest and most certain in its action is sterilization by ozone. Ozone is the ideal agent for water purification. It accomplishes its purpose without in any way altering the natural constitution of the water and at the same time leaves no trace of its presence. Water which previously was alive with dangerous organisms will, after proper subjection to ozone treatment, be in perfect condition for consumption. Moreover, its appearance and odor will have been improved, and it will have a sparkling brightness which, before the treatment, was absent.

A neat and efficient type of domestic Ozonair (British) sterilizer of this type, and using 45 watts of current, is here depicted. It has a capacity of 30 litres of water purified per hour.

Edison Heads New U. S. Navy Science Board

At last the American naval authorities, in the personage of Secretary Daniels, have awakened to the fact that battles of today, unlike those of yesterday, are really fought by scientists, either directly or indirectly. More and more it becomes apparent to even the layman that science, properly directed, can effect wonderful results when it comes to naval and particularly *land* battles on the scale upon which they are waged in this era.

Particularly is this noticeable in the reports from Europe, which state that the Germans are now using several kinds of highly poisonous gas guns, as well as gas bombs. But not only in the mechanical, but particularly in the electrical and wireless branches of science, are there most wonderful opportunities awaiting development.

To further the scientific development of military arms and devices in America, Secretary of the Navy Daniels recently sent out invitations to a number of the leading inventors and scientific men of the country. Thomas A. Edison, the peer of all inventors, has been selected to head the board of nationally famous inventors, which will include such men as Henry Ford, Simon Lake, John Hays Hammond, Jr., Orville Wright, etc.

The photograph herewith shows Mr. Edison and Secretary Daniels upon the latter's recent visit to Mr. Edison's home at West Orange, N. J., when plans were discussed.

THE WIRELESS TORPEDO IN THE "MOVIES."

The wireless torpedo, which has been heralded far and wide as the greatest engine of destruction ever invented by man, has been exploited of late in the Pathé film, entitled "The New Exploits of Elaine," episode "Shadows of War."

The illustration herewith shows the new fangled wireless antenna invented by "Craig Kennedy," the master scientist of this remarkable film story. In the photo are shown his assistant and also the heroine of the story in the person of Miss Pearl White. "Craig Kennedy" is seen holding the miniature wireless torpedo which possesses remarkable devastating powers, and in the series of pictures it is demonstrated how, quite like the "Hammond" wireless torpedo, it is possible to send out wireless waves from the radio apparatus and antennæ, as here shown. These waves will cause the little torpedo, carrying terrible explosives, to be directed toward a hostile war vessel and as soon as it comes in contact with the hull of the vessel it, of course, explodes with mighty violence, blasting its target into eternity.

Love, intrigue and science permeate this extremely interesting photo play, including efforts by a foreign government to procure the secret of this wonderful radio torpedo.

Pathe Film Episode Exploiting the "Wireless Torpedo."

cussed for the formation of the new Navy Board of Invention and Development. The idea will be to have this Board meet periodically and to thoroughly look into the merits of any inventions which may be submitted to the Government by the many inventors throughout the country.

It is undoubtedly true that in the past many worth-while inventions have been either smothered, so to speak, forever, or else they have been taken over by foreign governments, owing to inadequate facilities for examining such inventions.

The idea to be followed will be to have this Advisory Board of famous engineers and scientists so balanced as regards its personnel that all distinct branches of applied science to-day will be represented by undoubted leaders in those particular fields. Thus, any inventions submitted to this Board will naturally be given the best and proper attention possible. Proper laboratory and field arrangements are to be made for testing out such inventions in a practical way.

The English, and particularly the German, governments have long recognized that scientific men can help very materially in developing proper equipment and machinery for the defense of the nation. Such farsightedness will always repay a thousandfold the development expenses incurred, and it is the rankest kind of folly to expect that we or any other nation can even hope to cope with modern war problems with such a proportionately small army and navy as we possess. To offset this is the task of the new Board of Scientists.

SELENIUM CELLS AND RADIO TORPEDOES.

The problem of radio selectivity may be cast aside as one of secondary importance, and the real problem of keeping the enemy from tampering with the torpedo by means of their own wireless transmitter solved by the use of apparatus which will make them their own executioners, says B. F. Miessner in *Purdue Engineering Review*, in discussing radio-controlled mechanisms, etc.

In 1912, while associated with John Hays Hammond, Jr., he developed an apparatus which was called "An Orientation Mechanism." The principle involved in this machine has been applied to torpedo control with this same idea of making it hazardous for the enemy to attempt interference. This orientation mechanism, which has also been popularly called the "Electric Dog" (see June, 1915, issue of this magazine), in its present form consists of a rectangular box about 3 feet long 1½ feet wide and 1 foot high. This box contains all the instruments and mechanism, and is mounted on three wheels, two of which are geared to a driving motor (see diagram), and the third, on the rear end, is so mounted that its bearings can be turned by solenoid electro-magnets in a horizontal plane. Two 5-inch condensing lenses on the forward end appear very much like large eyes.

If a portable electric light, such as a hand flashlight, be turned on in front of the machine it will immediately begin to move toward the light and, moreover, will follow that light all around the room in many complex manoeuvres at a speed of about 3 feet per second. The smallest circle in which it will turn is about 10 feet diameter; this is due to the limiting motion of the steering wheel.

Upon shading or switching off the light the dog can be stopped immediately, but it will resume its course behind the moving light so long as the light reaches the condensing lenses in *sufficient intensity*. Indeed, it is more faithful in this respect than the proverbial ass behind the bucket of oats. To the uninitiated the performance of the psuedo dog is very uncanny indeed.

The explanation is very similar to that given by Jaques Loeb, the biologist, of reasons responsible for the flight of moths into a flame. According to Mr. Loeb's conclusion, which is based on his extensive researches, the moth possesses two minute cells, one on each side of the body. These cells are sensitive to light, and when one alone is illuminated a sensation similar to our sensation of pain is experienced by the moth; when both are equally illuminated no unpleasant sensation is felt. The insect threfore keeps its body in such a position, by some manner of reflex action, as will insure no pains, and in this position the forward flying motion will carry it directly toward the source of light.

The *orientation mechanism* here mentioned possesses two selenium cells corresponding to the two light sensitive organs of the moth, which when influenced by light effect the control of sensitive relays instead of controlling nervous apparatus for pain production, as is done in the moth. The

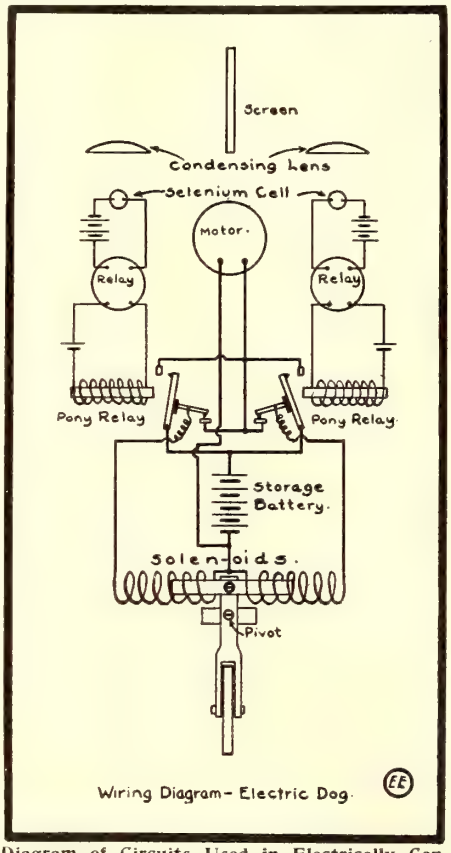

Diagram of Circuits Used in Electrically Controlled "Dog" Utilizing a Beam of Light and Two Selenium Cells.

two relays (500 to 1,000-ohm polarized preferred) controlled by the selenium cells in turn control electro-magnetic switches, which effect the following operations: When one cell or both are illuminated the current is switched on to the driving motor; when one cell alone is illuminated an electro-magnet is energized and effects the turning of the rear steering wheel. The resultant turning of the machine will be such as to bring the shaded cell into the light. As soon and as long as both cells are equally illuminated in sufficient intensity, the machine moves in a straight line toward the light source. By throwing a switch, which reverses the driving motors connecting, the machine can be made to back away from the light in a most surprising manner. When the intensity of the illumination is so decreased by the increasing distance from the light source that the resistances of the cells approach their dark resistances, the sensitive relays break their respective circuits and the machine stops.

The principle of this orientation mechanism has been applied to the "Hammond Dirigible Torpedo" for demonstrating what is known as *attraction by interference*. That is, if the enemy tries to interfere with the guiding station's control the torpedo will be attracted to him. The torpedo is fitted with apparatus similar to that of the "electric dog," so that if the enemy turns his searchlight on it, it will immediately be guided toward that enemy automatically.

In order that the searchlight used by the control operator may not have this same effect, use is made of a gyroscope to keep the turntable upon which the cells are mounted in a fixed position relative to the earth. In this way, no matter how much the torpedo turns, or in what direction it is traveling, the selenium cells will always face from the shore toward the attacking battleship in the open sea.

By means of two directive antennae, instead of two selenium cells, the same principle may be applied for attraction by interference when *Hertzian* instead of light waves are used. Sound waves might also be utilized in a similar manner, so the sound reaching the torpedo (which would be equipped with two submerged microphones, made sensitive and directive by megaphone attachments) from the pounding of the battleship's engines and other machinery would effect its attraction in a way analogous to the attraction of a source of light for the orientation mechanism. It is just possible, too, that similar apparatus could be used for the detection of submarines or for defense against them.

TWO GREAT INVENTORS WHOSE FORESIGHT DID NOT EQUAL THEIR INGENIOUS ABILITY.

Not infrequently great inventors do not comprehend the significance of the thing they have produced. An interesting anecdote of two famous men of science whose foresight did not equal their inventive ability appears in *Les Inventions Illustrées*.

When Hertz first began to obtain satisfactory results from his now famous researches into the possibility of transmitting electric waves certain men of science suggested that some day similar vibrations might serve to transmit messages through space. Hertz laughed at the hypothesis and assured all comers that his experiments were for laboratories only. Now, after a few short years, it is hard to find a single issue of a daily paper that does not record some noteworthy example of the use of wireless telegraphy.

Likewise with Levassor, the great engineer, who sketched the automobile with such skill that his first design has not been materially changed to this day. After Levassor accomplished his historic trip from Paris to Bordeaux and return at the dizzy speed of about 15 miles an hour his admirers gave him a banquet. During the toasts one of them stirred by the spirit of the occasion, arose and enthusiastically called on the assembly to drink to the approaching day when carriages should travel at the speed of 60 miles an hour. Levassor turned to his nearest neighbor and asked in a quick undertone, "Why is it that after every banquet some people feel called on to make fools of themselves?"

LAKE HOPATCONG, N. J., HAS RADIO CONTROLLED BOAT.

A motor boat on Lake Hopatcong, N. J., is operated by wireless from a tower at Woodport. It has a mast at each end, with five projections on one and seven on the other. James Wilson, New York, owns it.

How Telephone Transmitters and Receivers are Made

(Concluded)

ILLUSTRATION 6 and 7 portray the make-up and assembled views of the watch-case receiver. The reason why the longer style of receiver is employed for practically all commercial "Bell" equipment is because this design permits of placing longer and very powerful permanent steel magnets in it. The watch-case receiver is used extensively for telephone work also, especially as an auxiliary receiver, so that the person using a long-distance line may have a receiver at each ear, thus gaining the utmost efficiency acoustically by acting on both ears simultaneously.

For wireless telegraph and telephone work the watch-case receiver is the only practical form available so far, as the operator has to have a pair of receivers strapped on his head for hours at a stretch. The present wireless receivers are highly perfected indeed and, as their manufacture covers all the more important steps of this specialized industry in general, this discourse will conclude with their more important construction details.

First let us look at Figs. 4 and 6, where the component parts of the wonderful telephone reproducer of speech are depicted. Here we see the cap 1, made of hard rubber or composition. This threads onto the end of the receiver shell 5, and between them they clamp by its circular edge an iron diaphragm 2, about 2 inches in diameter. This magnetic (iron) diaphragm is acted upon constantly by a strong magnetic field created by a hard, magnetized steel member 4, of U section for long-type receivers and of circular or ring section for watch-case receivers, as Fig. 6 shows.

Fig. 7. Ultra-Sensitive Telephone Receivers Designed for Wireless Work.

On the permanent magnet 4 is mounted a pair (sometimes only one) of soft iron pole pieces on which are wound many turns of fine insulated copper magnet wire. For all regular telephone work the coils have a total resistance of 75 to 80 ohms. Wireless receivers have from 1,000 to 3,000 ohms resistance each usually, as the current used is very minute, or a few millionths of an ampere.

Each receiver shell, of course, carries suitable binding-post terminals 7, or some receivers have no posts. An insulating disc 6 (Fig. 4) is sometimes secured to the end of the shell 5 to carry the posts 7.

What we read previously regarding the scientific research on diaphragms for the transmitters holds good here also; only in that here the diaphragm is necessarily to be magnetic in character or at least must have an iron center. The design of the caps has been very thoroughly gone into, regarding their acoustic properties, etc.

The following details of manufacture applying to the wireless receivers will give a good idea as to the amount of fine work involved in their successful production.

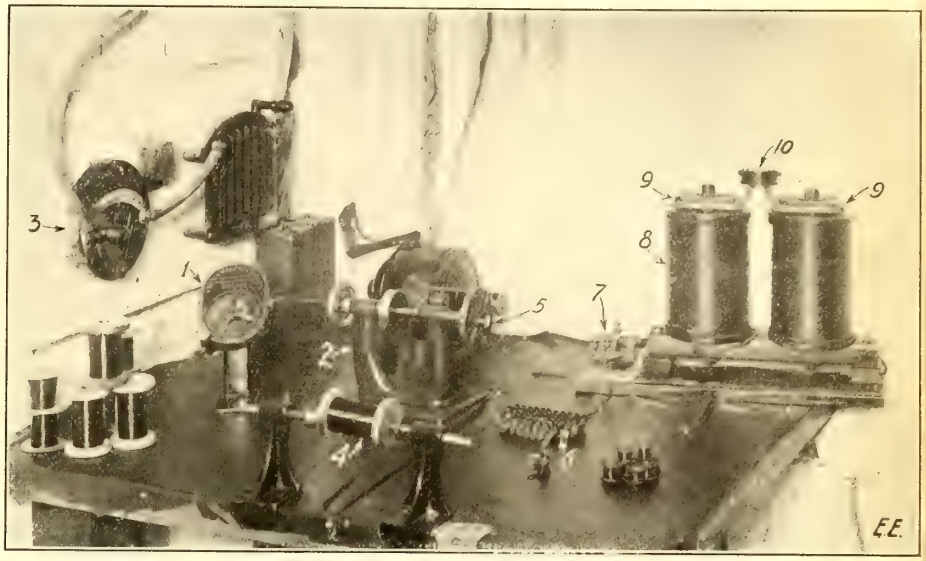

Fig. 8. Showing a Corner of the Winding and Magnetizing Shop Where Wireless Receivers Are Built.

The photograph (Fig. 8) shows one of the winding and magnetizing tables used in making the *"Electro"* radio receivers.

Materials Used.

The vital items in any receiver are the following: The permanent magnets, the wire used, the pole pieces, the diaphragms.

The permanent magnets in all wireless receivers are made of the highest grade tungsten steel, manufactured in Sweden. After the magnets are blanked or punched out to shape they are hardened glass hard. There is a big waste in this process, as many pieces warp so badly that they cannot be used. Each blank is then tested for hardness by an inspector and no blank that can be scratched by a file is acceptable. Such blanks are scrapped. Consider that this steel costs from 35 to 40 cents per pound before blanking, when domestic steel can be had for from 16 to 20 cents. Then consider that but 70 per cent. of the blanks pass inspection, and that a pound of the steel does not furnish many blanks indeed.

The pole pieces, which perform a very important function, must be of the softest possible iron. Nothing but the best grade of inspected Swedish iron will do, and not all grades are satisfactory.

The wire used in the receivers is imported enamel wire. It is No. 43 B. & S.—a wire so fine that the eye hardly perceives it. Only a specially trained operator can wind it on account of its great fragility.

There is at present no suitable No. 43 enamel wire made in the United States. None seem to have the high insulating values of the European wire, and the domestic wire of this size, furthermore, tears so easily that it cannot be used in a high-speed winding machine.

There have been some controversies as to the use of enamel wire for wireless receivers in the past. Exhaustive comparative tests have shown that enamel wire is infinitely more efficient. We cannot here go into a lengthy technical discussion as to the great merits of enamel wire; suffice it to cite the following: No one will deny that the more (ampere) turns one can wind on a given core, the better the electromagnetic results, always bearing in mind, of course, that the nearer the winding to the core the more efficient the electro-magnet will be. Thus, previously these receiver spools were wound with 5,700 turns of No. 44 B. & S. silk wire. Now there are used 6,600 turns of No. 43 B. & S. wire—a heavier wire (carrying more current) and winding almost 1,000 more turns wire in the same space, without increasing the distance between the pole piece and the last layer. This example makes it clear why the present highly perfected receivers are so infinitely more sensitive than they were previously.

"Resistance" is a very empty quotation in connection with a radio receiver. Thus, if we could use German silver wire in receivers it would be possible to save a large amount of money in manufacture. Of course, it is absolutely impossible to use this wire, for the reason that resistance wire "chokes" almost all signals. Not even satisfied to use good copper wire, the specifications for enamel wire invariably call for the highest grade electrolytic copper. This costs quite a little more, but it is possible to get from 1 per cent. to 3 per cent. better conductivity—an appreciable amount when we wind over 6,000 turns of wire on a bobbin.

The diaphragm is one of the least understood parts in telephone engineering to-day. The highest authorities have written books and pamphlets about it, there have been endless discussions, and it is quite safe to say that some millions of experiments have been made, in order to find out just how a diaphragm works. We only know this: We know mighty little as yet. In H.

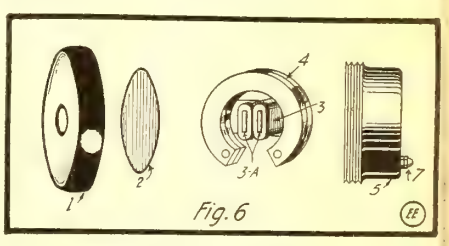

Fig. 6. Details of the "Watch-Case" Telephone Receiver.

Gernsback's laboratory, at New York City, can be found several hundred diaphragms made of strange materials, as well as in strange shapes. There are diaphragms of pure nickel, some of the new magnetic al-

loys, some made of the latest silicon-transformer iron, some with curious holes and curious laminations, some made of iron wires, some made of mica with iron center, etc., etc. Even when blanked out from the best calendered sheets, 25 per cent. of the diaphragms have to be scrapped. They do not all come absolutely flat. Some will be dished, some warped. Neither will the most careful inspection always reveal small defects; for when the receivers are finally assembled some will give a noise instead of a clear note. Thus it will be seen that the insignificant diaphragm is a very important as well as costly item.

Winding.

The most important as well as interesting operation is the winding of the very small telephone bobbin. A specially constructed machine does this work. Fig. 8 shows it; 1 is the automatic revolution counter, which counts the turns of wire on each bobbin. Each style receiver bobbin is wound to a certain number of turns. Thus each bobbin of a 1,500-ohm receiver is wound to 6,600 turns, while each bobbin of a 1,000-ohm receiver is wound to 5,500 turns, and so on. When the hand of the dial arrives at the, say, 6,600th turn, a bell rings and the operator stops. As the wire is remarkably uniform, the resistance of each bobbin will not vary for more than 1 to 2 ohms. The winding machine proper 2 is operated by an electric motor. The control of the machine is foot-operated. The speed regulator is shown at 3. The fine wire supply-spool is shown at 4, while the bobbin 5, in process of winding, is held in an ingenious chuck. Completed bobbins are shown at 6.

Only a thoroughly experienced female operator can wind the No. 43 wire at a high speed without having several breaks in each bobbin. It is a very hard task at best, very trying as well as tiring. It is also necessary to operate the winder at a high rate of speed, as else the wire does not "pack" tight enough. Thus an inexperienced operator can only get about 75 per cent. of the required wire on its bobbin. Naturally the machine must run very steady and smooth to obtain the correct results. After the bobbins are wound and equipped with lead wires they are tested by means of an ohm-meter. Those that test either too high or too low are discarded. The bobbins next go to the female assemblers who make up the complete receiver. Before they leave the assemblers' hands, however, the receivers undergo various tests and several inspections.

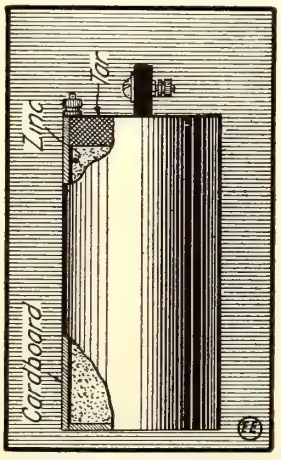
Calibrating.

The receivers are now placed in trays, each tray containing some 60 receivers. They are then taken to the calibrating machine, where the pole pieces, as well as the receiver shell edge, are machined down within 1/5000 of an inch accuracy. For it is of the utmost importance that the pole pieces are of quite equal height, and that the edge of the casing be a certain few thousandths of an inch higher than the pole pieces. Also the rim of the casing must be absolutely smooth and even as well as absolutely parallel with the pole pieces. This calibrating is a very tedious operation and can only be performed by skilled mechanics having long experience. This calibration process takes from eight to 10 minutes for each receiver. After the receivers have been calibrated they are inspected by means of a micrometric appliance to make sure that the pole pieces come to 1/5000 of an inch parallel with the rim. If the variation is too great the receiver must be recalibrated.

Magnetizing.

After calibrating, the receiver is ready to receive its magnetic baptism. Fig. 8, at the right, shows the apparatus that does it. The extremely powerful electro-magnets connect without any resistance to the 220-volt power current. A large manipulating key 7 serves to close and break the current, which circulates around the spools 8. When energized, this electro-magnet is capable of lifting over 500 pounds. Only a very powerful electro-magnet produces satisfactory receivers.

On top of the spools we see the adjustable pole pieces 9 9. On top of these the telephone receiver 10 is now placed by the magnetizing operator. The current is then turned on and broken a number of times, in a peculiar manner, while the receiver undergoes several mechanical treatments to age it. After a few minutes the receiver is completely magnetized, and is now tested once more, this time to ascertain if it is magnetically strong enough. The receiver, if passed by the inspection, now goes back to the assembling department. Here it is cleaned thoroughly and polished. Certain parts inside are then enameled and lacquered. After drying, the diaphragm, as well as the hard-rubber cap, is put in position and the receiver is finished. The receivers are then assembled on the head band, the cords are put on and the head set is ready for the final tests. The first test is for resistance. If this has been found correct the completed receivers are sent to the wireless room, where, by means of several ingenious instruments, the phones undergo several tests for sensitivity. Those not checking up with the standard are returned to the factory.



The final, supreme test is the wireless test in actually receiving signals. Phones not sounding clear and sharp are returned to the factory to be made over.

This completes the receivers. Each set is now tagged and signed by the tester, and the phones are then ready for packing.

The "Bell" receivers, etc., go through the different operations just mentioned, and in many cases they are tried out on *"artificial lines"* for talking power, as the inductance, capacity and resistance of the line all tend to affect the performance of the receiver as well as the transmitter. Standard transmitters are tested usually on 28 to 30-mile circuits in the testing laboratory. The phonograph has not substituted the human voice for these tests, strange as it may seem.

WAR AFFECTS CHANGE IN DRY CELLS.

Due to the present war conditions, which

have caused the market price of zinc to "sky-rocket" to dizzy heights, or in fact to about three times what it originally cost before the war, dry cell manufacturers have evolved a new scheme for cutting down the cost of the zinc outer shell electrode of such batteries.

As the sketch herewith shows, the zinc now is in the form of a very thin shell, only extending as high as the active element in the battery. At the bottom of the cell it simply extends to the base of the compound element and no zinc disc is used as a bottom, as formerly. Also, to protect this thin zinc shell, a heavy cardboard covering suitably impregnated to withstand the action of the chemicals is placed over the entire battery.

ABOUT RADIO TORPEDOES.

Several well-known electricians have expressed the opinion that the new wireless torpedo will be ineffective, owing to the liability of its control being lost, through interference by waves from other wireless sending appliances. This objection was raised when the idea was first advanced by Nikola Tesla, but it is claimed by the inventor of the Hammond system of wireless direction and operation that this liability has been eliminated. In a long series of tests made by the operators of the wireless outfit on the United States steamer "Dolphin," said to contain the strongest wireless sending plant in the United States, interference was shown to be impossible until within 250 feet of the torpedo.

Voting Results.

It gives us pleasure to publish herewith the final results of the voting contest between the readers of the *Electrical Experimenter.*

In the June issue we printed a Voting Blank, asking our readers to fill it out by giving their preference of the various departments. The idea proved a huge success.

It was astonishing as well as gratifying to the publishers how much interest was evidenced in this contest. A surprising and quite unexpected feature was that 68 per cent. of the voters thought so much of their magazine that they did not want to cut out the voting blank. Instead, they copied it on a piece of paper! Frankly, we had never thought of that!

Up to July 24, 6,286 votes had been received, and they are still coming from all parts of the globe—China and Brazil included!

Six thousand one hundred and fourteen were satisfied with the magazine as a whole; 212 made valuable suggestions—some of them very valuable; 172 criticised us—some harsh, some mild—on various subjects. Some of these wanted nothing but wireless, some nothing but "How-to-Make-It," and so on.

On the whole, every voter seemed well satisfied. The following table accurately shows the tabulated preferences of 6,286 readers. It requires no comment, except that we will be guided by the wishes of our readers and we will give them exactly what they ask for, in the proper proportions:

"How-to-Make-It" Dept.	1
"Wireless" Dept.	2
The Constructor	3
General Electrical Articles	4
"Münchhausen"	5
Electrical Experiments	6
Among the Amateurs	7
Question Box	8
Magazine Review	9
Latest Patents	10

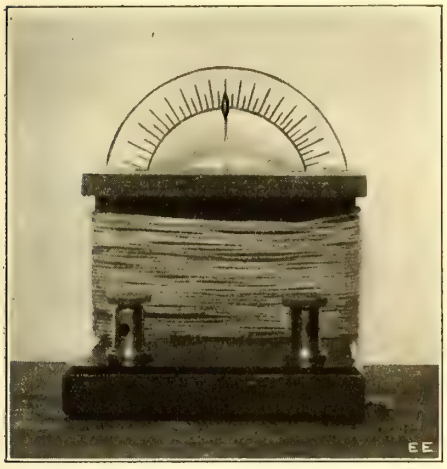
The average age of our voters proved to be 18. The extremes were as follows:

Of the 6,286, 12 were 11 years old, and 16 were 48 years old.

After passing the 20-year stage we found 96 to be 21 years old and 64 were 22 as well as 29 years old.

How to Construct a Galvanometer.

A USEFUL galvanometer is easily made up as described below. The woodwork used presents no difficulty. Any well-seasoned wood can be used—in the present instance some odd pieces of mahogany came in very well. After the frame has been made, wrap several layers



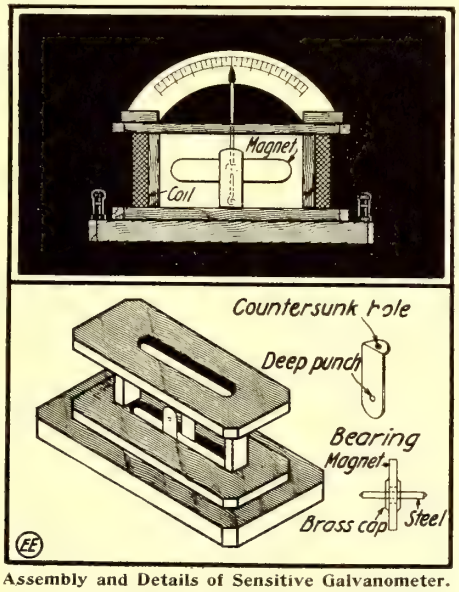


Photo of Complete Galvanometer. (Four Posts Being Used; Only Two Shown.)

of wire around the bobbin itself. The wood can be finished to the fancy of the maker. A good rubbing with linseed oil makes a quick and lasting finish and safeguards against dampness.

There are two magnetic windings. The first is a high resistance winding of two, even, close layers of No. 30 D.C.C., although a little finer would be even better. The beginning and finishing ends are led through two small holes at one end of the bottom flange. This winding is then given a good coat of shellac varnish, and a strip of brown paper is then laid over it which is also shellacked. The outer winding is two close layers of No. 20 D.C.C., also well shellacked, forming the low resistance coil. A finishing cover of varnished paper can be laid over this, if thought necessary. The two ends of this winding are taken through two holes in the other end of the lower flange.

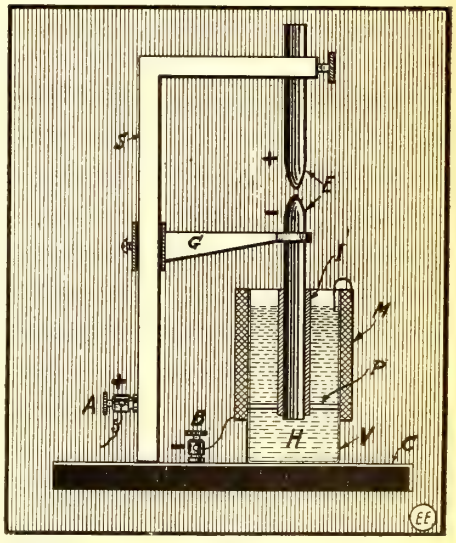
The magnet is a strip of steel cut from a small hack-saw blade. It may be annealed in a Bunsen gas flame to be soft enough to cut and drill. Round the ends nicely, and exactly in the center drill a 3/16-inch round hole. Now take a short piece of ¼-inch round brass. Shoulder (in a lathe) one end down to 3/16 of an inch for about ⅛ of an inch; pass this small end through the hole and rivet it over. Cut off the remaining ¼-inch end, leaving 1/16 of an inch projecting from the steel, and you will have a nice boss in which to mount the spindle. Now place the steel in a bright, clear fire, and as soon as it has reached a dull red heat lift it out and at once drop it into a basin of cold water. It will now be very hard and brittle. Next carefully clean it up with fine emery cloth and drill a 1/16-inch hole exactly in the center of the brass boss. To make the spindle get a knitting needle (steel, of course) that is just a shade too large for the hole. Very carefully force it through with gentle blows. File down the ends of the spindle until they are brought to points, which must be central and finish quite smooth. The final smoothing can be done with a narrow strip of the finest emery cloth glued on a slip of wood. Do not make the points with too long a taper. When finished, the over-all length of the spindle should just exceed one-half inch. Now you may magnetize the steel blade as strongly as you can—either by stroking it many times with one pole of a strong magnet, or by passing a strong current of electricity for a minute or two through a coil of wire wound around it.

The pointer and balancing counterpoise can now be attached. They are made from a piece of the No. 20 D.C.C. wire with the insulation removed, and are fastened to the brass boss with just a drop of solder. Just a word of warning here: Do not make the soldering too long a process, or the heat of the "iron" will weaken your magnet. To avoid this you might magnetize the steel after the soldering is done, though it is not then quite so convenient. The lower end of the counterpoise is formed of a small loop of the wire filled with a little blob of solder. By holding the ends of the spindle lightly between the finger and the thumb, a little manipulation

Assembly and Details of Sensitive Galvanometer.

of the counterpoise will cause the magnet to rest horizontally with the pointer vertical.

THE CONSTRUCTION OF AN EXPERIMENTAL ARC LAMP.



An arc lamp, whereby the essential features of this illuminating device can be demonstrated, can easily be made as shown and described in this article. While the lamp here shown, does not have the refined feeding mechanism with which commercial arc lamps are provided it will operate under the conditions specified and will show how electrical energy can be converted into light.

The electrodes *E* are lengths of electric light carbons. The upper carbon is supported by an upright *S*, which should be of metal, inasmuch as it comprises part of the electrical circuit. In operation the current should enter the binding post *A* and leave at the binding post *B*. The base *C* is a block of wood. On this base is carried a glass or metallic vessel *V*. An iron sleeve *I* should be fitted over the lower end of the negative electrode. This sleeve should fit snugly so that the friction between it and the electrode will hold it in place. This sleeve has two functions. The first is to provide good electrical contact between the negative electrode and the mercury in which its lower end floats, the second is to provide a supporting medium for the guide pins *P* which will be described later.

The metal guide *G* which holds the negative carbon in line with the positive carbon is supported on but insulated from *S*. Three pins *P* screwed into the lower end of the sleeve *I* guide the lower end of the negative electrode.

The solenoid *M* consisting of about 100 turns of No. 14 gauge insulated copper wire is wound around the upper part of *V*. One of the terminal wires of this solenoid connects to the binding post *B*, while the other dips into the mercury *H* with which the vessel is filled.

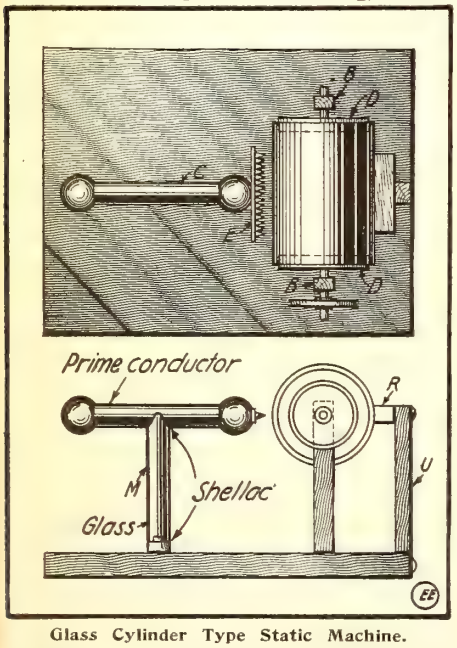
Now we will trace the electrical circuit through the lamp. The current enters at *A*, passes through the metal stand *C* to the positive electrode. Then it arcs to the negative electrode and passes down it and into the mercury. The path is then through the coil or solenoid *M* and to the negative binding post *B*. With this, as with every other arc lamp, a resistor of a few ohms resistance and of sufficient capacity to carry the current of the lamp, must be connected in series with the lamp. Every electric arc must have, for reasons which cannot be discussed here, in series with it, either a reactance or a resistance as "ballast." The lamp here shown when connected as described will operate on a 110-volt circuit. The principle of operation is this: When the switch is closed and current is permitted to pass through the lamp, the negative electrode which ordinarily is forced upward by the pressure of the mercury into contact with the positive electrode, is drawn downward by the electromagnetic action of the solenoid *M*. That is, when no current is passing through the solenoid the lower end of the carbon encased in its iron sleeve floats in the mercury just as a cork floats on water.

Construction of Simple Automatic Feed Arc Lamp.

The mercury buoys the negative carbon up against the positive carbon. As the lamp burns the electrodes are consumed, which increases the distance between them and tends to increase the resistance of the circuit. The current through the solenoid

M is thereby decreased and its electromagnetic effect proportionately reduced, hence the negative carbon is permitted to rise. It is evident therefore that this lamp feeds itself automatically.

It is not essential that carbon be used for the electrodes of this lamp. Metallic electrodes can be used instead. While the metallic electrodes will burn away much more rapidly than those of carbon, they will provide light of certain qualities that may be desired to satisfy certain specific conditions. For example, with the positive electrode of steel and the negative of carbon a light which is very rich in actinic rays is produced. This kind of light has the property of acting very rapidly on photographic plates. Actinic rays of light are sometimes called ultra-violet rays. Where experiments are being made with ultra-violet rays, the eyes must be shielded from their effects by *clear glass spectacles*. Otherwise inflammation of the eyes and other ailments may be produced. Clear glass has the property of sifting out ultra-violet rays—they cannot pass through it. Contributed by



J. A. GILMAN.

THE CONSTRUCTION OF A FRICTIONAL ELECTRIC MACHINE.

A FRICTIONAL or static electrical machine can be made as shown in figure. With this device many interesting experiments in static electricity can be performed.

In any frictional machine it is necessary that some insulating material be arranged to rub against a dissimilar material. Theoretically, the friction or contact between any two dissimilar materials will develop frictional electricity, but it has been found in practise that the friction of glass against a certain amalgam, which will be described, gives the best results. The apparatus shown herewith is an arrangement whereby a glass cylinder is made to rub on an amalgam.

The glass cylinder can be about 4 inches outside diameter and 6 inches long. This cylinder can be cut from a jar or bottle. Or else the jar or bottle can be mounted between two bearings without cutting, after a

Glass Cylinder Type Static Machine.

manner that will immediately suggest itself to the experimenter. If a glass cylinder is used, two disks of dry wood *D* are fitted into its ends and cemented there with shellac. The axle is a metallic rod about 8 inches long and ¼ inch in diameter. This axle should be cemented into the end pieces *D* with shellac. The bearing blocks *B* should be of dry wood about 6 inches high, 1 inch wide and ⅞ inch thick. Each is fastened in place on the base block by a couple of flathead screws, turning up into them from the bottom of the block. A ¼ inch hole is bored in the upper end to accommodate the axle.

If the cylinder is to be turned by hand a wooden crank is arranged at one end of it, but if an electric motor is available for driving it a wooden pulley is mounted on and cemented to one of the axles. All of the wooden parts of the machine should be thoroughly dried and varnished with two coats of shellac. The cushion *R* is a block of wood about 4 inches long and ⅞ inch wide. It is wrapped with five servings of flannel and then covered with two additional servings of silk cloth. This cushion is secured after the cloth has been wrapped around it to the end of a wooden upright *U* with one or two wood screws. Before the cloth is wrapped on the cushion the edge of the cushion block that is to bear against the glass cylinder should be rounded out somewhat so that it will approximately have the curvature of the cylinder. After the cushion block and upright are in place the cloth on the block should bear firmly against the cylinder.

In operation the cushion should be well coated with an amalgam compound as follows: Melt together two parts of zinc and one of tin. While these metals are fluid add to them six parts of mercury. Now pour this alloy into a wooden box and agitate the box until the alloy is cool. Before applying the amalgam to the cushion it should be mixed with a small amount of lard so that it will stick to the cloth.

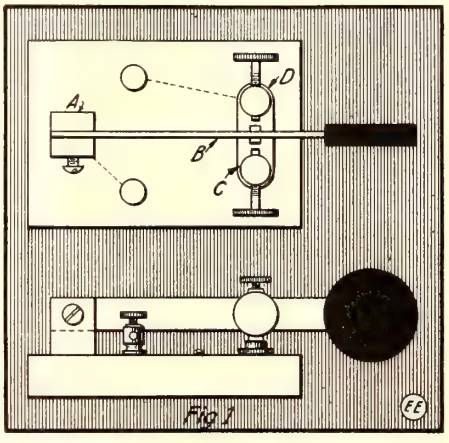
The prime conductor *C* is made of brass tubing. A piece of tubing having an outside diameter of 1 inch and a length of about 4½ inches will serve the purpose. At each end of this tube a brass ball about 1½ inches in diameter is soldered. The ball should be smooth. Such balls can be obtained from window curtain fittings. The comb *E* is made by inserting in a strip of sheet brass about ⅜ inch wide and 4 inches long a number of brass tacks or brads. These points should not be more than 3/16 inch or ¼ inch apart. The head of each point should be soldered to the comb strip. This comb strip is now soldered to the prime conductor *C* as shown.

The prime conductor support *M* is shown as a piece of glass tubing, but a stick of sealing wax can be used. Glass is the better material. At its lower end *M* fits over and is shellacked to a wooden boss, which is held to the base with a wood screw. At its upper end the prime conductor *C* is cemented to *M* with sealing wax or shellac. After the prime conductor is fixed in position it should be of such a height and so arranged that the points of the comb will be no further than 1/16 inch from the glass cylinder. Furthermore, the points should be on a level with the center line of axis of the cylinder.

In using this frictional machine it should be carefully cleaned with a dry rag or a camel's hair brush and should be warmed before a fire to drive off any surplus

(*Continued on page* 208.)

HOW TO MAKE A "BUG" KEY.



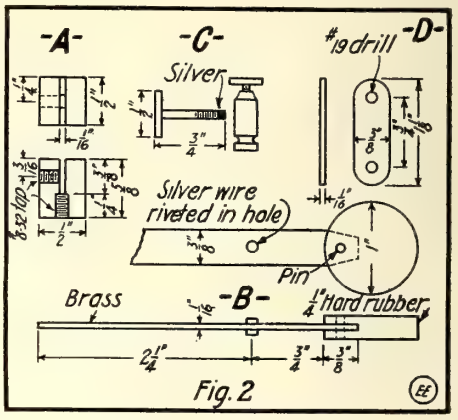
"Bug" is the name given double-contact telegraph keys that use a horizontal instead of a vertical motion. Although these do not possess all the advantages of the automatic keys, they are far superior to the ordinary key and therefore worthy of a place in every radio or telegraph station.

Ease of construction is one of their advantages, and this will be apparent by a glance at the drawing. I have given all the dimensions necessary, but a few words will not be out of place.

A piece of hard rubber is used for the base, but fiber, marble or hardwood may be used with good results. The holes are drilled with a No. 19 drill, or large enough to pass the 8/32 screws as used to hold the various parts to the base. The edges of the base may be beveled off with a file.

The standard A to hold the spring is made from a piece of ½-inch square brass rod ⅝ inch long. This has a hack-saw slot ⅜ inch deep cut in it and two holes drilled and tapped as shown.

The lever B, of phosphor bronze or spring brass, is 3⅜ inches over all without the knob attached, ⅜ inch wide and ☆ inch thick. This will be found to have about the proper tension, and no adjustments will be found necessary. The lever has a piece of silver wire riveted into a hole in the

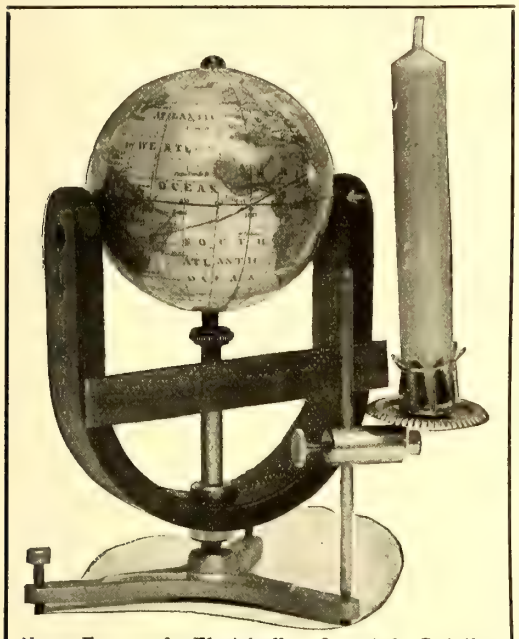


Making a "Bug" Telegraph Key.

position shown in Fig. 2, and is fastened to the knob by inserting one end into a slot cut into the knob and held there by means of a small pin driven through, as is also shown.

Four common binding posts, the two contacts C C (Fig. 2) and the small brass strap D complete the list. The contact pieces C C have short ends of stout silver wire soldered onto their heads.

Assemble these parts as per drawing and you will have one of the handiest instruments you could own. The knob is held lightly between the thumb and forefinger and moved from side to side, remaining in each position long enough to give the necessary dot or dash.



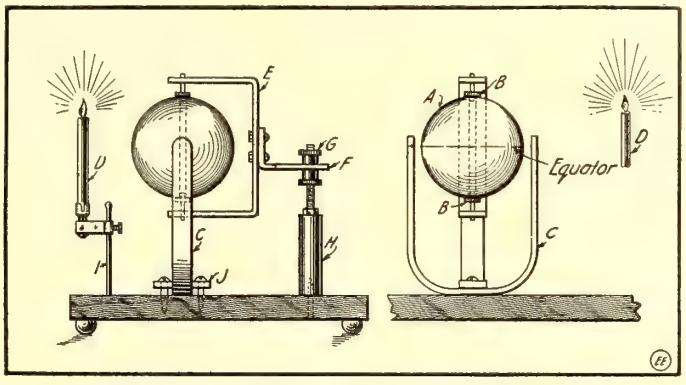
Details of "Bug" Key.

If the base is polished and the brasswork nickeled, the appearance of the "bug" will be greatly improved. Contributed by

THOMAS W. BENSON.

NOVEL EARTH GLOBE WHICH ROTATES ELECTRICALLY.

A striking model of a revolving earth globe, on which is painted a map of the earth in the regular way, has recently been brought out. This model has a sphere A,



New Form of Electrically Operated Rotating "Earth" Model.

delicately mounted between the poles of a strong permanent steel magnet C, as the illustration shows. The sphere measures 2½ inches in diameter, but this may be varied somewhat in case the experimenter intends building one.

The peculiar part about the sphere is that the upper half of same is made of very thin copper, which can be provided for by using a hardwood ball of the proper size and hammering the copper over same with a wooden hammer in the same way that coppersmiths do such work. Attached by glue or otherwise to this upper copper hemisphere is a lower hemisphere made of Bristol board or paper, etc. Suitable supporting means is suggested in the sketch, E and F being made from brass as well as the rest of the parts, excepting the steel magnet C. This magnet may be secured to the base by a piece of brass or wood J, together with a few wood screws. A brass rod I serves to support a candle holder and candle D, as observed.

This model is found to operate best when the source of light or candle flame, etc., strikes the sphere midway between the equator and the upper pole of the sphere. *Even the light from a match will cause the sphere to rotate.* In some cases a slight push may be necessary to start it, but invariably it does so automatically. The vertical position of the sphere is important and it should be tried out at different heights with respect to the magnet poles.

Why does the ball turn? is the question often asked. No one knows precisely. There are many theories or "explanations." Among them is that of the German scientist, Albert Lotz. He suggests that magnetic forces, in conjunction with the sun's heat, are constantly operating like spiral tides or gently wheeling currents to turn our globe around. This little revolving earth model is intended to illustrate this theory. Whether the theory be true or false, it is interesting to see it given such clear and attractive expression.

Details of Construction for Rotating "Earth" Model.

A DRY STORAGE BATTERY.

The average cyclist seems hardly to appreciate the value of electric lighting for his bicycle; he is accustomed to using the old form of oil or gas lamps and only recently several manufacturers have brought to the attention of the public electric dry battery bicycle lamps.

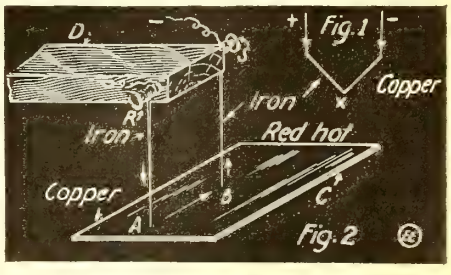
The main disadvantage is in the dry cells used. These batteries are not intended for continuous use, but for intermittent service, and the question then arises, "Why may not a storage battery be used?" This is readily answered in the following: The regular storage battery, as made to-day, contains a very corrosive acid, known as sulphuric acid; the container of same must be kept open by means of a vent during the working of the cell, as gases are constantly being given off. For this reason they cannot be readily used on bicycles, as any vibrations would cause the acid to spill, resulting in serious damages.

The writer, having experienced the above-mentioned difficulties, gives herewith two simple methods for converting a liquid storage battery into a dry type, which may be used in connection with a vehicle or for other portable work, with success. The first method consists of the following:

Make a paste mixture of some ordinary sawdust, immersed for 20 hours in a zinc chloride solution, which can be obtained from any chemical house at 10 cents a pound. After the sawdust has been saturated in the chloride solution, it should then be allowed to dry for about 12 hours. Then wash the sawdust in several hot waters to thoroughly clean it, then dry again. Having done this, fill the storage battery with this mixture and add the sulphuric acid, having the same specific gravity as if the battery were ordinarily used. It should then be charged as usual, and it will be found that by shaking or inverting the battery, the solution will not spill; the sawdust mixture has absorbed the acid and at the same time is pressing against the plates, giving them a live acid surface.

The second method: Fill the cell full with ordinary glass wool, and add the acid until the wool is completely saturated. This glass wool may be procured from glass blowers.

It will be found that the above-mentioned methods of converting a wet storage



(*Continued on page* 208.)

DEMONSTRATING THE PELTIER CURRENT EFFECT.

The materials required for this experiment are a few good primary cells—or, better, a storage cell—a flat piece of copper sheet, two binding posts, a few steel needles and a small piece of wood. Thus equipped we are about to demonstrate the "Peltier effect."

First let us state what that effect is, says R. E. N. in *Model Engineer*. Referring to Fig. 1 if we pass a current through iron and copper wires twisted together at X to form a series circuit the junction will be *heated* when current passes from iron to copper and *cooled* when current flows in the opposite direction. This effect is not the ordinary heating effect of an electric current. As the temperature increases the Peltier effect decreases till it becomes zero at 280° C. (535° F.); at higher temperatures it reverses, so that heat is developed at the junction when current is sent from copper to iron and cooling is produced when current flows from iron to copper. It must be understood clearly that ohmic resistance at the junction produces the same heating whichever the direction of current flow. The Peltier effect simply adds to or subtracts from this heating.

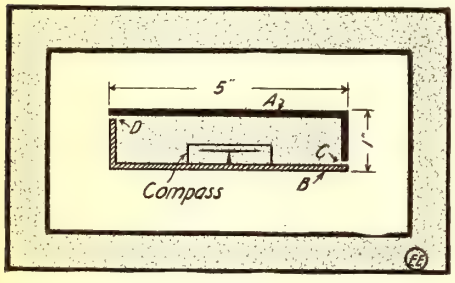
Suppose now that we fix binding posts R S in one end of a piece of wood D, Fig. 2, and clamp leading-in wires and steel needles in these terminals, so that when the other end of D rests on the table the points A B rest evenly on the sheet of copper C. Current can now be passed from R to S through a steel needle, the copper plate and another steel needle in series. On starting the experiment the needle tips are cool and the junction A (iron to copper) is heated and the junction B (copper to iron) is cooled by the Peltier effect. If, however, 4 or 5 amps. be passed through the circuit the needle tips soon get warm, because their section is very small and their resistance therefore relatively high. The junction A reaches the critical temperature (280° C.) before B; but soon both needle tips are hotter than this, and then the Peltier effect is reversed and the tip B becomes hotter than A, so that ultimately B becomes red hot, while A is still invisible in the dark (the lowest red heat visible in the dark is about 335° C. or 635° F., while "dull red" heat is about 700° C. or 1,290° F.). Owing to the small weight of metal in the needle points, the small amount of heat produced or absorbed by the Peltier

The "Peltier Effect" of Electric Currents.

effect produces quite considerable temperature rise or fall, and thus permits one tip to become red hot appreciably sooner than the other. If the current be great enough both needle tips will soon be red hot, but that one becomes red first where current leaves the copper plate. If the weight on the two needles is distributed evenly the needle tip A will become red hot first when current is reversed, thus proving that unequal resistance is not the cause of the phenomenon. A fresh pair of needles should be used often. The effect is best seen in a subdued light.

A GOOD THERMO-ELECTRIC CELL.

The form of thermo-electric cell described below was discovered by J. T. Seebach, a noted German physicist. The cell will prove of interest and moreover is cheaply constructed.



First obtain two metal strips, A and B, about 6 inches long and 1 inch wide; one of German silver and the other of copper. Bend them as shown in figure and then solder the ends together, thus forming a rectangle 5 inches long and 1 inch high.

Now mount a small compass upon the upper side of the lower strip. Place the arrangement upon a non-combustible base and the cell is complete.

To use bring a match or some form of heat near the soldered joints, D or C, and the compass needle will turn slightly, thus proving that an electric current can be generated by heating the union of two dissimilar metals. The wattage of such a cell will be about 1-50 of a watt, and since so much heat is required the cells are not commercially a success, although by using several cells in series-multiple an electric lamp can be lighted.

By soldering two wires to the cell, one to each strip, the following experiments may be tried:

(1) Connect a set of batteries to the two wires and place a drop of water upon the joints. The water will either freeze or boil, and by reversing the battery current the reverse will take place.

Thermo-Electric Cell Which Produces Heat or Cold.

(2) By arranging one corner joint in ice water and the other joint in warm water a current of about 1-12 volt and ¼ ampere may be taken from the two wires, but the wattage obtained in this way will depend upon the following: Surface heated; difference in temperature; metals used; condition of union, etc.

(3) By using antimony and bismuth for the legs of the cell and different patented arrangements experimenters have succeeded in producing a respectable amount of electricity in this way.

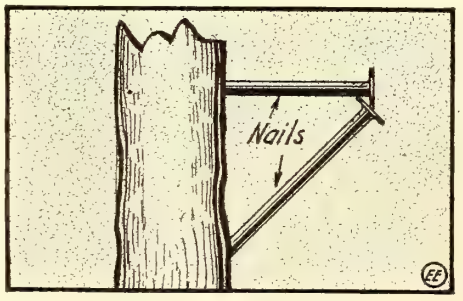
The Marconi Wireless Telegraph Co., Ltd., reports net profits for the year ended Dec. 31 last of £232,700, an increase of £110,400. The report states that the directors decided to reduce the dividend on the ordinary shares from 10 to 20 per cent., in order to strengthen the financial position of the company.

A CHEAP ELECTRIC EGG TESTER.

The expression "fresh eggs" cannot always be depended upon, and my little device, herewith described, can be used in any suspicious case.

Make a wooden cabinet 8 inches high and 3½ inches wide. Then procure a 3-volt "Radio" cell and place in a box as



Inexpensive Electric Egg Tester.

shown. In a small socket screw a bulb of at least 2½ volts, and with some stiff wire connect to battery as depicted. Now secure a wooden ring and fasten to a bracket in cabinet. If this cannot be done, make a ring from some very thick wire and tack to side of cabinet. Obtain a wooden cover, and after attaching a plain eyepiece, drill a hole in the center of the cover and fasten to box by hinges. Finally, bend the bulb in position, so that it is just in the middle of the ring when peering into the eyepiece. The hard rubber mouthpiece from an old telephone is a good substitute for an eyepiece.

When the light is turned on and the egg is in place the brilliancy of the bulb gives the egg a dim glow and the freshness is thereby determined by the quality of the glow. The darker the glow, the older the egg. A small lamp shade may be fastened to ring if desired. Contributed by
W. WESTON.

TEMPORARY POLE STEPS.

Cheap but safe pole steps can be made with 5-inch spikes. Spike one is driven in at an angle of 45 degrees, then spike two is driven in horizontally so that it rests on

Pole Steps Made From Nails.

the head of spike one. The wireless experimenter will find these useful for ascending trees and poles to erect his aerial.

A SMALL WINDING MACHINE.

Every amateur, I am sure, knows how disagreeable it is to wind a magnet by hand. Herewith is described a simple machine involving only the use of an electric motor, a rheostat and some shafting.

First mount the motor about 8 inches from the edge of your table. Then procure and fasten two wooden posts in an upright position as shown. Before fastening, however, drill a hole on the end of each one, all the way through, to admit a long, slender steel rod. The latter is to be next obtained and a pulley fastened, as shown in sketch. The next step is to fasten a home-made rheostat on the left hand leg of the table and putting it in connection with some cells and one binding post of the motor. The sketch explains clearly all wiring. Now fasten a cord on the handle of the rheostat, attach a spring to it and fasten the end of the string to a foot treadle secured to the floor by hinges. (A piece of board will serve for a treadle.) Lastly, on the left hand corner of the table drive a long, thin nail, but without a head, as otherwise the spool cannot be slipped on and off. The device is now complete, and without a doubt will work satisfactorily.

To wind a magnet, put a spool of wire on the long, thin nail on the edge of the table and slip in a wooden bobbin to receive the wire on the steel rod, which is belted to the motor. By means of the foot treadle the hands can be used to control the winding of the wire evenly and the foot to control the current, by means of

Simply Made Electric Winding Machine for Experimenters.

the rheostat. If the wire begins to wind unevenly, raise your foot, thereby lifting the spring on the handle of the rheostat, which shuts off the current at once. For further operation, press treadle again with foot. Contributed by W. WALLACE.

THE CONSTRUCTION OF A FRICTIONAL ELECTRICAL MACHINE.

(*Continued from page* 206.)

moisture. Then the cushion should be connected to ground—a gas or water pipe, or merely a wire leading to the floor will suffice. Now if the cylinder is rotated rapidly a stream of sparks, that is, a discharge of electricity will pass between the points of the comb and the glass cylinder.

When the hand is brought near the end of the prime conductor a minute lightning discharge will occur between them and an electric shock will be experienced. *Under favorable conditions a spark as long as 2½ inches may be produced.* Any of the usual experiments in static electricity can be readily made with this device.

Sayville, the News-Way to Berlin.

NOW that the powerful German Wireless Telegraph Station, located at Sayville, L. I., has been taken over by the United States Government authorities by order of the President, to further the purpose of preserving our strict neutrality, this remarkable plant, about which so much secrecy has always been observed, has become of extraordinary interest to practically every one in this country.

Owing to the great secrecy which has always surrounded this station and the operation of same, there have been many wild tales prepared and published by various newspapers throughout the country, as to many *possible* and also a great many *impossible* schemes, which might have been employed in order to send undecipherable code messages to Germany, via the Nauen station, located near Berlin, which works in conjunction with Sayville in this country.

This plant is one of the largest in the world now, since the two new 400-foot steel towers have been erected and in view of the fact that the dynamo equipment for generating the wireless waves has been increased from about 35 kw. to 100 kw., or in other words the transmitting power has been tripled in order to insure absolute communication, under all conditions and particularly through the heavy static obtaining during the summer weather.

The illustrations herewith show the wonderful aerial structure at Sayville, which towers over 500 feet above the ground. The mast here shown is the central one of the three now available for the wonderfully enlarged antenna system.

Photos (C) by Underwood & Underwood.

Interior View of the Wonderful "Sayville" Radio Station. Above, the Aerial Structure 500 Feet High. Three Masts Are Now Used and 100 Kilowatts.

This station embodies a number of very ingenious and advanced features in radio installations not found in other stations, generally speaking, and about which very little has been said or published indeed. Among these important features are the means by which transmission and reception of signals is effected. To begin with, the high power used at Sayville has always been handled by automatic transmitting keys of the relay type. The operator, as here seen in the picture showing the interior of the station, operates an ordinary Morse key mounted on the desk in front of him. This small key controls the massive relays of the air-cooled type, of which there are three. Each relay has eight series contacts on it, and thus the current is broken through a plurality of 24 contacts. This conduces to rapid and positive operation of the transmitting circuit in sending out the dot and dash signals, which occur, of course, at the rate of many signals per minute. These relays are specially designed and are capable of operating at a speed of 150 words per minute.

Of course, no manual operator can attain a speed of much over 50 words per minute, even in a radio station, but the higher speeds such as mentioned are obtainable with this Telefunken system, as the transmitting has been done for many months and also at present, by means of a perforated paper tape, which is prepared on a machine similar to a typewriter, with a lettered keyboard. Once this tape is prepared with proper perforations corresponding to the dots and dashes of the Continental radio code, it is then passed through the automatic transmitter device, which actuates the heavy current relays aforementioned.

Suffice it to say that everything connected with this plant is of the very best and latest type. Particularly is this noticeable in the reception of radio signals from across the broad Atlantic, as for this purpose it is not necessary for the operator to wear the usual head 'phones on his ears, as will be noticed particularly in the illustration here shown.

Signals coming in from Nauen, Germany, pass through a specially tuned microphonic form of amplifier, which may be observed mounted on the pedestal directly in front of the operator. This am-

The Above "Code" Diagram Shows How Secret Cipher Messages Could be Interspersed Through Regular Messages.

plifier so marvelously increases the power of the signals as picked up by Sayville's antennae that when they reach their final stage they have been boosted sufficiently to enable them to operate a loud-sounding signal horn, so that the signals sound through the room similar to the striking of a piano string. Of course, it is perfectly feasible and possible, if desired, to make a tape record on a register of these signals as they come in, by hooking up the recorder to the final stage of the amplifier circuits.

As recently pointed out editorially in this journal, it is very true that, by means of the usual "cipher" code, it is undoubtedly possible for parties desiring to do so to send through a message which may appear very innocent indeed on its face, and yet when received in Germany, and by referring to a copy of the special "cipher" code involved, a distinct and very useful meaning may thus be carried through by such a message, even though *every person* connected with the Sayville station belongs to the United States Government personnel.

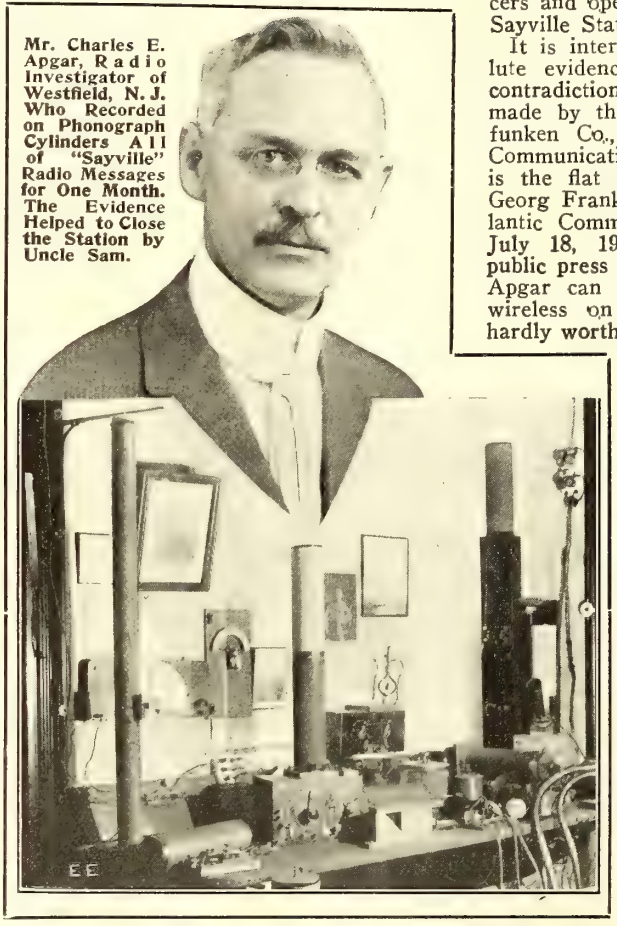
There have been many fantastic stories published in the newspapers, as aforementioned, and particularly with regard to a special invention of Dr. Isidor Kitsee, of Philadelphia, which some have claimed was used for the transmission of secret code signals *interspersed* with the regular signals employed for transmitting via Sayville ordinary-looking messages which the United States censors at Sayville passed through readily enough. While such an invention or code scheme could be used, it is doubtful that it was ever actually used.

It might, however, be of interest to point out how this could be accomplished. The code diagram herewith will show how the scheme would work in practise, and we think it is doubtful whether under ordinary conditions the United States Government censors would detect anything unusual about such a message. Furthermore, it could be *repeated a number of times* with variations, in order to make up a complete code for the alphabet. The fact also remains that such a lengthy repetition of a similar message for a period of several days, it is reported, was one of the deciding factors involved in the Government seizure of this station.

By referring to the code diagram here reproduced there is seen the word "Berlin" with corresponding Continental code dot and dash signals used in transmitting this word via radio. Glancing at the second line, it is seen how the spacing of the dots and dashes in a couple of letters comprising the word "Berlin" could be abnormally arranged. This abnormal spacing, strictly speaking, can be very minute, in view of the fact that if these particular signals were copied on a register at Nauen it would then be easily possible for the operator at that station to note the small difference in these "doctored" signals. By making these spaces different, or by using a certain space in a certain letter to represent a letter of the (cipher) alphabet it would be possible indeed to send a complete code message. By duplicating the same (regular message "apparently") time after time, it would ordinarily not arouse any undue suspicion.

Another scheme which could be followed would be the interposition of additional dot signals in the regular code make-up, as the third line in the diagram illustrates. Note the signal for "B," where an extra dot is added, and also the extra dot which is added in between the letters "E" and "R." It is quite improbable that these would be detected under usual conditions, especially as the messages sent through this station can be transmitted at a marvelous rate of speed.

This "doctoring" of the regular code signals could be managed by a small attachment of an electrical nature, perhaps, which could be fitted secretly to one of the automatic paper tape perforators or to one of the magnetic key transmitting mechanisms so as to abnormally space certain dots or dashes.



This matter is simply brought out to show that it is possible to conceive a secret cipher code, even in the face of strict censorship as this term is generally interpreted or understood, as for instance, prior to the complete occupation of this station by the United States naval personnel.

Why Sayville Radio Station Was Closed.

ADDITIONAL light has recently been thrown on the matter of the closing of the powerful German radio station at Sayville, L. I., and its reopening by a full Government staff.

A quantity of simple phonographic wax records, which were taken over a period of about one month prior to its seizure by Uncle Sam, were recored at the experimental wireless station of Mr. Charles E. Apgar, at Westfield, N. J.

We illustrate herewith the apparatus in Mr. Apgar's radio station and his wonderful amplifying set, whereby he has been enabled for the past few years to record faithfully all kinds of wireless messages on phonographic wax records. To put the matter briefly, the "canned" evidence that really closed the Sayville station, as far as the Telefunken company's operation of same was concerned, was started back on the 7th of June, 1915, on the advice of the United States Secret Service. W. J. Flynn, Chief of the Secret Service Bureau, took up the matter with Mr. Apgar at that time, and every night thereafter all of the wireless messages sent out from Sayville by the Telefunken operators were faithfully copied on a phonograph at the Westfield experimental station.

Mr. Charles E. Apgar, Radio Investigator of Westfield, N. J. Who Recorded on Phonograph Cylinders All of "Sayville" Radio Messages for One Month. The Evidence Helped to Close the Station by Uncle Sam.

Each morning the messages were transcribed from the wax cylinders verbatim, and sent at once to Mr. Flynn, either at New York or in Washington, wherever he happened to be on that day. While Mr. Apgar does not wish to commit himself unduly regarding this matter the Editor can truthfully state from what he has stated that it was really his absolutely faithful records of all of the signals sent out from Sayville that caused the United States Government to seize the famous station.

Further, it can be stated that secret messages, in code and otherwise, were thus sent along with regular censored messages, and it may be judged that some of these were incriminating enough in their nature, to cause the Government to act as it did on July 9, when United States Naval officers and operators took full charge of the Sayville Station.

It is interesting to note also that absolute evidence is available in writing in contradiction to many of the statements made by those connected with the Telefunken Co., also known as the Atlantic Communication Co. Of particular interest is the flat statement made by Dr. Karl Georg Frank, general manager of the Atlantic Communication Co., under date of July 18, 1915, when he stated in the public press that—"The statement that Mr. Apgar can record messages sent out by wireless on a phonographic cylinder is hardly worth discussing. That is physically impossible. I have never heard of it being done. If Mr. Apgar has accomplished it he should get his idea patented and perhaps we will buy it."

Interesting, indeed, is the evidence of another nature on the same subject and which is contained in a letter submitted to the Editors of this journal, bearing the above company's letter head, marked and dated Feb. 5, 1914, or about one and a half years previous to the above statement by Dr. Frank. In this letter addressed to Chas. E. Apgar the Atlantic Communication Co., per their Mr. M. Boehme, state that "they shall be pleased to have Mr. Apgar deliver some of his phonograph cylinders, containing wireless message records to them." This Mr. Apgar did on Feb. 9, 1914. This letter is signed by Mr. Boehme himself and also the records delivered are receipted for by Mr. Boehme.

The wireless method of transmitting intelligence is undoubtedly one of the most subtle and flexible known to modern science and it seems that whenever a system is devised to transmit "untappable" messages, then someone will find a way to decipher them.

Mr. Apgar employs an Audion detector in conjunction with the perfected Armstrong circuits whereby it is possible to get wonderful amplification of the signals received and also with but one Audion bulb. Undamped wave stations are picked up very clearly; so well in fact that at his station wireless signals from Nauen, Germany, have often been heard. With the

The Hammond Radio Controlled Torpedo Boat

Although numerous and multifarious hair-raising inventions are claimed to be in use by foreign governments in the present titanic struggle for the supremacy of Europe, it is doubtful whether there is a more promising invention than that of the young American, John Hays Hammond, Jr.

Most of us have read in the daily papers from time to time of the wonderful wireless control effected by Mr. Hammond's invention, and we present herewith a photo of his latest torpedo boat, "The Natalia." The other photo shows Radio Operator Lee manipulating the wireless key at the Hammond laboratory on shore which controls the emission of wireless waves of various lengths, which when received by the radio antenna on board the automatic torpedo boat serve to make possible complete control of the movements of the boat.

The United States Government has detailed from time to time naval officers at the various trials conducted at the Hammond wireless laboratory at Gloucester, Mass. They have been highly pleased with the performance of Mr. Hammond's truly marvelous radio-mechanical craft, which seems to inherit almost superhuman intelligence. This may be better appreciated if we mention that from the time the boat has started from the pier until it returns from its run, which in some cases has totaled 28 miles, no human being is aboard. Truly uncanny is this meritorious device, and it bids fair to revolutionize modern warfare methods.

The United States Government is seriously considering the purchase of the entire rights to this radio control scheme, as worked out by young Mr. Hammond and his associate scientists and engineers. It would be of inestimable value for the protection of harbors, and as it can carry as much as 4,000 pounds of high explosives and as it also could be directed from shore directly at or toward any hostile warship it is seen that a very powerful weapon is thus placed in the hands of our coast defense corps.

It has been reported of late that the Japanese Government has been negotiating for the exclusive rights to this invention, but undoubtedly the American naval authorities will be wide awake to the far-reaching merits and properties of such a system and we hope that it will take up the matter very shortly, so as to control all rights thereto in the proper manner.

The Hammond Wireless Torpedo Boat Controlled from Shore Station (At Right) Through Special Radio Waves. It Has Covered 28 Miles Without a Human Being on Board.

ON THE CAUSES OF IONIZATION OF THE ATMOSPHERE.

By J. A. Fleming, M.A., D.SC., F.R.S.

There has been much discussion among radio engineers regarding the possibility of an upper ionized strata of atmosphere which might affect long-distance day and night wireless transmission. After some explanatory remarks Dr. Fleming goes on to say: "Since quartz is not transparent to wave lengths of less than about 1,850 A.U. (Angström wave length units), and since this quartz light will not ionize air, the proof is tolerably complete that no true ultra-violet light ionization of air can take place at low levels in our atmosphere. If there is any such ionization as proved by the electric conductivity, then it can only be due to photo-electric action on dust, ice particles, or to radioactive matter in the sea or soil, or some indirect photo-electric process which yields negative ions.

"On the other hand, solar light, owing to the high temperature of the photosphere, probably does contain rays of short wave length lying within the Schumann (2,000 A.U. to 1,000 A.U.), and Lyman (1,000 A.U. to less) regions. Hence, even although the ionizing potential of oxygen, nitrogen, hydrogen and helium is 9 volts and upward, a true ultra-violet light ionization may take place in the levels of the atmosphere lying perhaps above 10 km. or 20 km. height.

"This, however, does not explain the possibility of a permanently ionized layer. It would merely account for a diurnal layer ionized by day or in the side of the atmosphere facing the sun and disappearing by night. To account for the permanently ionized layer, which it has become the custom, though as the writer thinks somewhat unappropriately, to call the Heaviside layer, it is essential to show cause for the production of ions of one sign only at some high level in the atmosphere. Good reasons have been given for supposing that the photosphere of the sun principally consists of carbon, probably condensed into flakes of soot or granules, and that the temperature, at any rate of its outer portions, is about 6,000 to 7,000 deg. C. Now we know that such incandescent carbon not only sends out ether wave radiation but emits positive and negative electrons, chiefly the latter.

"It is a comparatively easy matter to calculate the velocity and time of passage from the sun to the earth of such ions of various sizes under the action of solar light pressure. We start with the known facts that the Maxwell light pressure in dynes per square centimeter is numerically equal to the light energy in ergs per centimeter cube, and that the best value of the solar constant is 2.1 gram calories per square centimeter per minute, or 1.47×10^6 ergs are imparted per second to a perfectly black surface by normally incident bright sunshine corrected for atmospheric absorption. Hence it follows that the light energy per cubic centimeter is 49×10^{-6} ergs, and the light pressure nearly 5×10^{-6} dynes per square centimeter at the earth's surface. Light intensity at the sun's surface is, however, 46,000 times greater than at the earth's surface, and hence the light pressure at the sun is 2.3 dynes per square centimeter. These figures show that one cubic mile of sunlight at the earth's surface contains light energy equal to 14,710 foot-pounds, and the light pressure is 2.8 pounds per square mile. At the sun's surface the light is 58 tons per square mile and the light energy per cubic mile is 302,300 foot-tons, or energy enough to throw 20 of H. M. S. 'Queen Elizabeth's' 15-inch shells over the top of Mont Blanc.

"According to the most recent mathematical investigations by Prof. A. E. H. Love, who has confirmed results obtained by Prof. H. M. Macdonald, the full discussion of the problem of diffraction of long electric waves round a sphere seems to indicate that with waves 20,000 feet in wave-length diffraction alone will account for the daytime propagation of radio-telegraphic waves over such distances as 3,000 miles. Whether this be so or not, it is perfectly certain that some additional agency is at work in the night time. The onus rests on those who reject the theories built on atmospheric ionization to substitute for them some other valid explanation of the irregularities and generally greater range of night-time signaling.—*The Electrician*, London.

European Applications of Wireless Telephony.

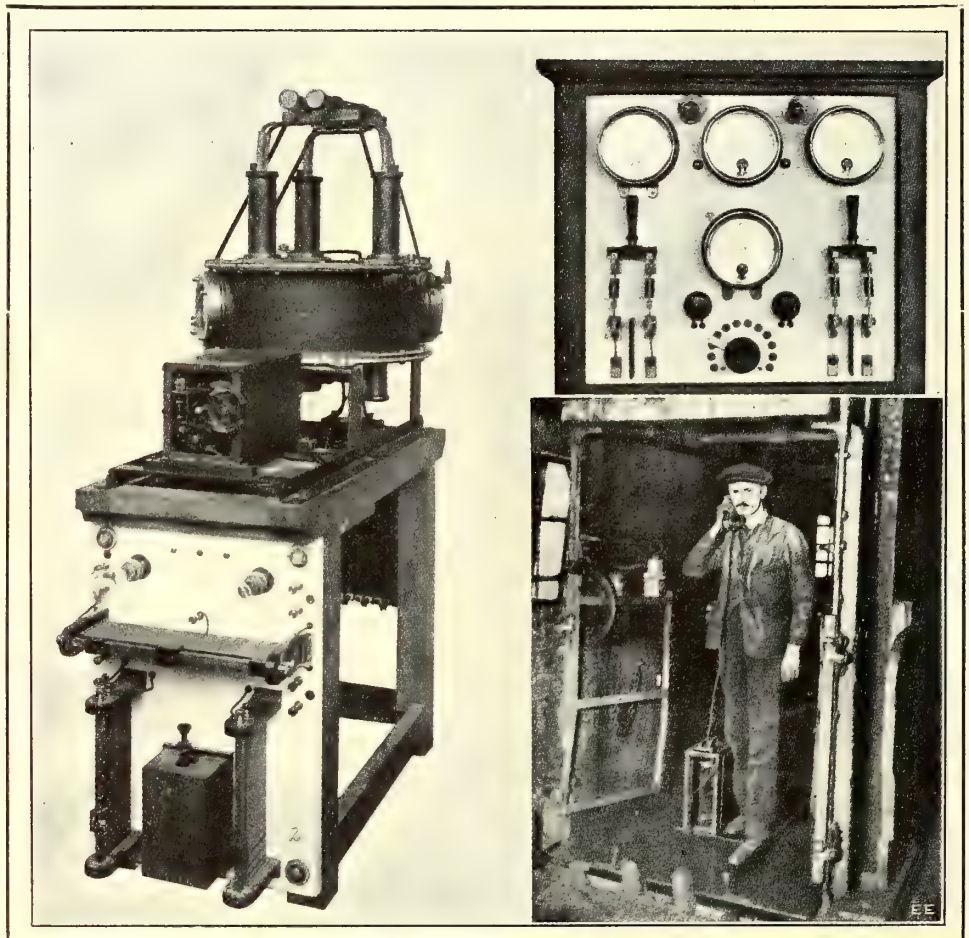
By Frank C. Perkins.

THE accompanying illustrations, Figs. 1 and 2, show the switchboard and electrical apparatus utilized in the wireless telephone system developed at Paris, France, by the Compagnie Générale de Radiotélégraphie, and having a radius of action of about 200 kilometers (about 125 miles).

This French system developed by Colin-Jeance is supplied with current from a dynamo of 500 to 750 volts and from 3 to 4.5 amperes being used. The tension of the arcs in the oscillating circuit varies from 250 to 350 volts, a variable condenser being placed in parallel with the arcs. The current intensity used in the antenna is 3.5 amperes, while the microphone current intensity is .5 amperes, the wave length being 985 meters.

In the accompanying illustration may be seen apparatus of the Reineke wireless telephones for mines, utilized in Germany and in England, the photograph showing the operator speaking from mine cage to engine house.

Engineer T. M. Winstanley Wallis pointed out to the Institution of Mining Engineers that in Germany, as in England, the Government had for some time past urged the installation of telephones in mines; and as the usual troubles in the way of damage to wires occur equally in Germany as elsewhere, Herr Reineke, the inventor of this system, experimented with the view of overcoming these difficulties.



This system is in regular use in the Carolineneglück Pit, Bochum, Westphalia, where no other method of signaling is used and the Wireless Telephone Co., Ltd., of London, has been introducing the system in English mines. It is pointed out that in using the term "wireless" it is advisable to explain that the system is entirely distinct from that commonly used in wireless (or spark) telegraphy, as there are serious objections to such systems that would prevent its general use in mining work.

It may be said that in the wireless telephone the transmission and reception of the speech occur in a similar manner to the ordinary telephone, but there the resemblance ends. Instead of the current from the transmitter being conducted along the wire to the receiver it is converted to high pressure by means of a transformer contained in the telephone case. As the high pressure or secondary winding of the transformer is connected to the ordinary rails or pipes in the pit, it communicates to them a charge of electricity, which spreads over the whole system of rails throughout the pit, and varies with the fluctuations of the primary current in the transmitter circuit of the telephone. It is unnecessary to make any special provision to insulate the rails or pipes, or to connect the adjacent lengths electrically.

It is said that the invention resulted from the discovery that the conditions of distribution of electric charges underground are entirely distinct from the conditions that hold on the surface of the earth, and the working of the system largely depends on this fact. Speech can be received by connecting telephones to the rails or pipes at any point of the system, either by bridging a sufficient length so as to obtain a suitable difference of pressure, or by connecting between the rails and pipes if these exist; or, as is sometimes convenient in the case of portable instruments, by connecting to an antenna consisting of a loose coil of wire, which may be laid on the floor or hung on the timbers.

It may be stated that, as in the ordinary telephone, a bell is used for calling attention, the bell being operated by a specially designed relay. On the button being pressed at the transmitting stations all the telephone bells will ring and all the telephones can receive the message by taking the receiver off the hook, which operation cuts off the bell and connects the receiver in the usual manner. It is possible to tune the relays so that each will respond only to its own particular signal, and thus any one station can be called, but in mining work this is usually not necessary or desirable, and the different stations are called by giving one, two or three rings, as prearranged, while it is always possible, by a special signal, to call all the stations and speak to all simultaneously.

In the Reineke wireless telephone system for mines the current required is furnished by an ordinary battery; in fact, in outward appearance the telephones are exactly similar to an ordinary mining telephone. The portable instrument, which can be carried about and used in any part of the pit to which the rails extend, is contained in a strong metal case, the total weight being about 20 pounds. This telephone can either "ring up" the other stations or be "rung up" by them. A smaller or pocket instrument is also made, which can ring up other stations, but cannot be called by them.

At Left, New French, "Colin-Jeance" Wireless Telephone Apparatus. Top (Right) Switchboard For This Set. Below (Right) New Type of Mine Wireless. Telephone Devised by Herr Reineke, of Germany.

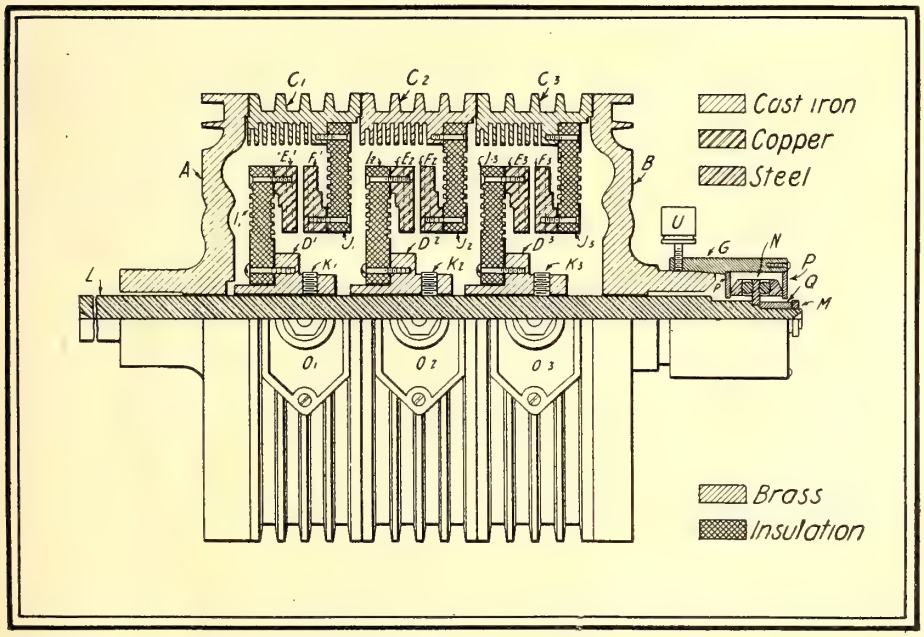
It is pointed out that with the Reineke wireless telephone instrument for mines messages can be sent to or received from any of the fixed telephones, the only difference between it and the heavier portable type being that the other telephones cannot call it by ringing its bell. Thus each official provided with an instrument can give notice of any accident and ask for assistance from any point in the pit. A telephone can be fixed at any convenient position on the surface and connected to the headgear, if of iron, or to the winding rope or pipes which go down the shaft.

It is maintained that this telephone can speak to any of the telephones underground if necessary, but it is usually found more convenient to arrange for it to speak to the station at the pit bottom only and for this station in turn to speak to the underground telephones. In metalliferous mines, where a number of different levels run from the shaft, communication can be established from one level to another as required, the presence of the ore bodies not affecting the speaking in any way.

A most important application of the system is that of speaking from the moving cage to the winding engine house, and for the latter position the inventor has designed an ingenious method of operation. The telephone is mounted on a standard fixed close to the engineman's ear. On receiving a call he has only to put his ear to the receiver and a slight pressure is sufficient to switch in the telephone and enable him

to communicate with the cage without removing his hands from the levers.

The advantages of this wireless mining telephone are many, and it is absolutely safe, there being no possibility under any conditions of producing a spark.



The inventor's claim that it provides complete security of communication, as there are no connecting wires to be interrupted and it can be easily removed from one place to another if required, while it cannot be affected by or affect other electric circuits in its neighborhood, whether these are direct or alternating currents conveying power or used for signaling, nor is it interfered with by ordinary wireless telegraph signals.

It is held that the opinion of the Continental experts who have exhaustively tested the telephone has been universally favorable and indicate that in this system a means of underground communication has been provided which is entirely free from any of the objections that have hitherto prevented the general use of telephones in mines.

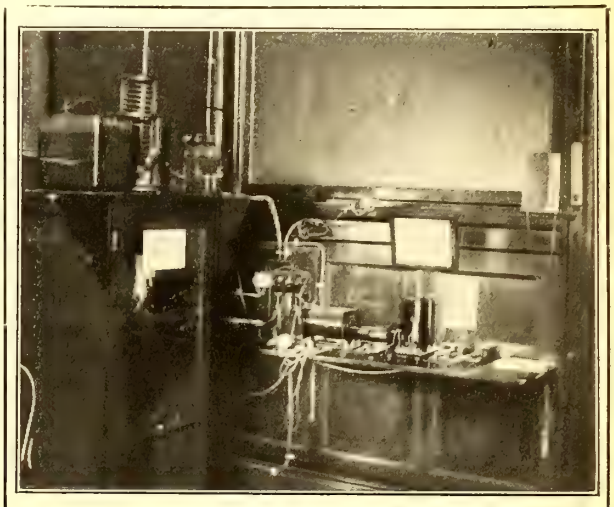
THE HYTONE SPARK GAP.

The average experimenter is not very familiar with the working parts and operation of the hytone gap, about which much has been said. This new gap is of the rotary quenched type, several units being used in series, the number depending on the power rating of the set.

The construction is shown in figure which is a cross-section. A small motor (1-3 H.P.) is directly connected to the shaft "L," which rotates inside of the case housing "A C B." Bakelite discs "I" are screwed at their center to hubs "D" and at the outside to copper rings "E." Opposite each copper ring "E" are two copper half rings "F," supported on Bakelite pieces "J." The gaps are connected in series, and terminals are brought out from each through insulating bushings. A double thrust ball bearing "N" is mounted in a nut "G," so that the distance between the rotary and stationary electrodes may be adjusted. These gaps are made very accurately and very skilled mechanics are needed in building this device, as the distance between the rotary and stationary plates is only .003 inch (.075 mm.). The sparking surfaces are made of copper and both rotary and stationary plates are milled with 36 radial slots, so that when rotated at 1,000 R.P.M. the tone corresponds to that of a 540 cycle alternator. It is necessary that the width of the sparking segments be so proportioned that the sparks occur during not more than one-half of the total time, as otherwise the receiver telephone diaphragm is retarded on its excursion away from the magnet, thereby resulting in a decreased sound intensity. A great many experiments had to be made before such results were obtained.

The Highly Efficient Rotary-Quenched Spark Gap (Hy-Tone) Produces 500 Cycle Tone Spark From 60 Cycles A. C. Etc.

WIRELESS TELEPHONY DEVELOPMENTS.



For several years the problem of wireless telephony has been handicapped by the need of a microphone which could handle considerable currents, and thus little progress was made in this direction until investigators began to get away from recognized paths. Various systems have been tried from time to time, such as the T. Y. K. system of Torikato, the Janke system with the Poulsen arc, that of Ditcham, and that due to Colin and Jeance and others, but without any very great success. The new highly rarefied vacuum tube, however, has put a fresh weapon at the disposal of the investigator which promises to revolutionize present methods. Certainly, in one direction or another advances are being made very rapidly at the present time, and something in the nature of a revolution seems to be coming about. The reaction vacuum tube is now being applied to wireless telephony by the Marconi Co. The tube is partly used for the production of continuous oscillations and partly for the magnification of the signals that are received. One of the most interesting points is the fact that extremely small aerial currents, such as 0.2 ampere, are sufficient to enable speech to be transmitted a distance of 70 km. Telephone sets on this principle, delivering 0.6 ampere to the aerial, are now sufficiently commercial to be guaranteed for a distance of 50 km. between ships at sea, and thus radio telephony is coming into its own.

WIRELESS AIDS TELEPHONE SYSTEM.

Using the wireless in a business that is built entirely upon wires seems an anomaly.

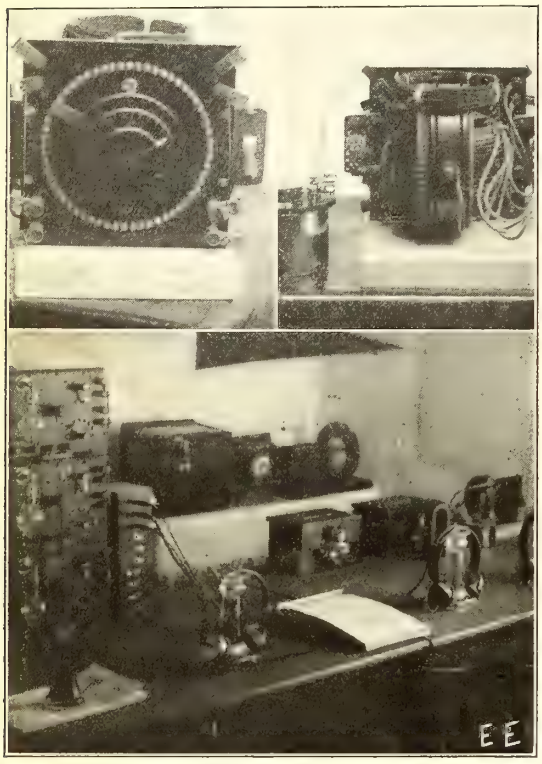
But that is what the Pittsburgh & Allegheny Telephone Co. is doing. The telephone business, of course, depends upon wires. Without wires the telephone is useless, for invention has not yet evolved the wireless telephone in perfect form.

As a valuable supplement to the wire business, however, the wireless is a vital factor. The truth of this is attested by the fact that the Pittsburgh & Allegheny Telephone Co. has developed a wireless organization as a distinct department of its business. The main station is in Pittsburgh. Eight branch stations are established at points in western Pennsylvania, eastern and central Ohio and parts of West Virginia—throughout the territory in which the company operates its telephone system. Trained operators, working the company's secret code, keep in daily touch with the big station in the Miller building in Fernando street, Pittsburgh. The most distant station in the organization is at Erie, Pa., a distance of nearly 200 miles.

Wireless Set Used to Extend Operation and Usefulness of Regular Telephone System.

The need for the wireless became apparent when a storm of wind and sleet last winter threw down a great number of poles.

Now the company is ready. If another storm does the damage that was inflicted last winter the company can get into communication at once and continuously with every part of its system. The whole situation could be handled and directed right in the Pittsburgh office and the innumerable delays of last winter obviated.



Practically all the apparatus in the Pittsburgh station was made in the company's shops in the Miller building. All the transmitting apparatus except the sending key is enclosed in the soundproof case. The receiving apparatus is placed on the shelf. The aerial is 170 feet long and 100 feet high, and is composed of four vertical and four horizontal No. 10 copper wires insulated with high-voltage insulators. The ground wire is composed of 125,000 circular mils area stranded copper rubber-coated cable.

In connection with their professional interest in wireless as an aid to the telephone business, Messrs. Muhlheizler and Weaver have encouraged the large number of young amateur wireless operators who have set up stations in western Pennsylvania. Largely through their efforts the Radio Society of Western Pennsylvania was organized.

Some Remarkable Results With Audion Amplifiers

By John A. Gardner and E. R. Isaak

I AM presenting herewith photos and drawings of some of our circuits, and will try to give a partial description of same. This covers our radio station at Eureka, S. D.

Views of Specially Arranged Loose Coupler and Complete Audion Receiving Set Used by Messrs. Gardner & Isaak Very Successfully.

As can be seen from the photo, our receiving set is of somewhat elaborate design. It consists briefly of tuning coil and rotary condensers, two audion detectors connected in cascade so as to amplify the signals, and three one-step amplifiers to amplify the signals as they come from the detectors. This arrangement makes use of five audion bulbs and their circuits for amplifying the signals. The amplification is so great that different parts of the circuits set up siren or whistling effects which effectually put a stop to the operation of the set or further amplification. In this article I will outline the special circuits we had to devise to make possible the efficient working of the many amplification units in one set, without being hampered by siren effects.

In Fig. 1 is shown the circuits for cascade connection of two audion detectors using one 6-volt storage battery to light both filaments. This is different from recently published circuits of the cascade connection using two batteries for heating the filaments, and it will be noticed that the 35-volt battery is shifted to a different part of the circuit in the first detector from where it would be if they were not connected in cascade. Tests seemed to indicate that this circuit not only amplified as much as the one using separate batteries for heating the filament but amplified quite perceptibly more.

This circuit may be used for receiving from the continuous wave stations by slightly changing the adjustment of the heating current and 35-volt battery current of the first detector. We use the magnet shown in the cut for helping to attain this adjustment, and also with the bulb we are using in the first detector now the magnet seems to increase the strength of signals from the spark stations. In use it is set in the position shown in the illustration. For the impedance coil shown we are using the secondary of a ½-inch spark coil. This is perhaps not the best that could be designed, but it works well. The iron core is, of course, left in place.

Fig. 2 shows the circuits of the plug box and amplifier. The plug box allows either one, two or three head sets to be connected to the third-step amplifier, the second-step or the first-step, and one head set can be plugged in on the second detector of the cascade set. This is invaluable for testing at any time the relative amount of amplification of the different amplifying units. The plug box is so wired that the head sets are connected in series. The weakening of the signals from plugging in two extra head sets is scarcely perceptible. This is owing to the extremely high resistance of the vacuum space in the amplifier bulbs. The additional resistance of one or two 4,000-ohm head sets makes little difference.

The first-step amplifier differs from the second and third only in the design of the transformer. It seems very necessary that the secondary of the transformer of potential circuit be not connected direct between the grid of the audion or amplifier bulb and the filament, but that a very small condenser, usually bridged by a very high resistance *made of slate or a pencil mark* be interposed in the circuit. The purpose of the high resistance is to prevent the bulb becoming paralyzed by static or strong signals, and should not be any lower than is absolutely necessary to accomplish this effect. The audion detectors seem to have only the condenser, but it is likely there is enough leakage through the wood of the containing box to accomplish this effect. In the second and third-step amplifier circuits shown the capacity between the two transformer windings is sufficient, and the illustration shows the adjustable high resistance made of slate that we are using.

As shown, the cascade-connected detectors are operated from one 6-volt storage battery, the first and second-step amplifiers from another, and the third-step from still another. This combination seems to be the only one we could work out that would give the maximum amount of amplification and operate without siren effects.

Fig. 3 shows views and part of circuits of our tuning coil. We consider this coil to be superior to any we have ever seen described. It will cover any wave length up to 16,000 meters or more without perceptible loss of efficiency from "dead ends" or from the volume of wire necessary to be used in a coil to cover the longer ranges, giving very close adjustment over the entire range. Every turn of the primary is inductively connected to every turn of the secondary, which is not the case where

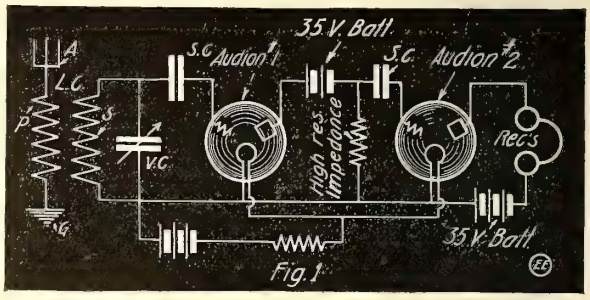


Fig. 1. Double Audion "Detector" Hook-Up.

tuning coil and loading coils are separate units, and the coupling of the entire tuning coil can be varied to about zero by simply turning a knob. The additional turns of wire up to the entire capacity can be added to either primary or secondary, or both, the windings being inductively connected in the most efficient manner, a flexibility not possible if tuning and loading coils are made in two or more separate units. They are arranged to be thrown in or out of the circuit by throwing the switch or telephone switchboard key shown in diagram, which dead-ends both ends of same when throwing them out of circuit.

It is a well-known fact that the audion is a potentially operated device, and that with

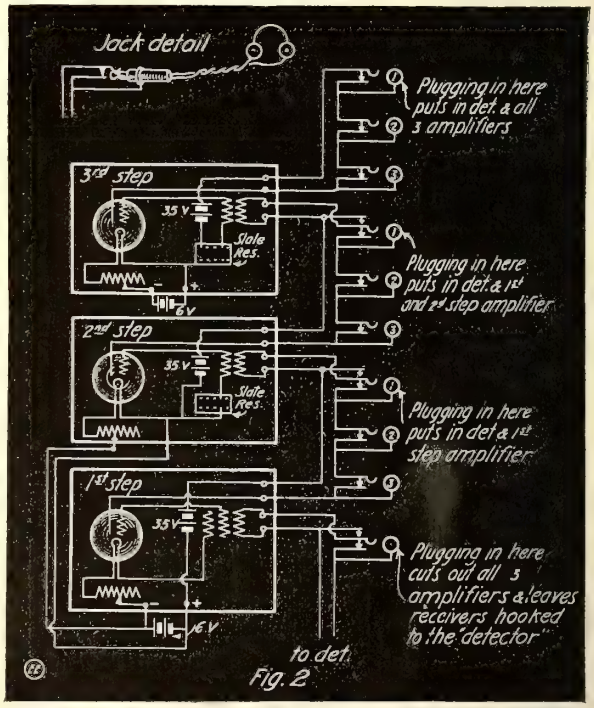

Fig. 2. Diagram of 3 Audion "Amplifier" Bulbs and 'Phone Jack Circuits.

a given tuning coil the signals are louder when the same wave length is tuned to in the secondary circuit, by using more wire and less condenser, than when using less wire and more condenser.

This effect can be carried out to the point where an ordinary variable condenser is adjusted to nearly zero and more wire is used in the secondary to get the correct wave length with a very perceptible gain

in the strength of signals. The flexibility of this tuning coil allows this to be done, and hence the great superiority of this design for a tuner to be operated in connection with an audion. Arlington tunes in here with but 29 turns of the original primary winding, while for the secondary we use zero condenser and *five times* the original secondary winding.

Our aerial is "T" shaped, and each half

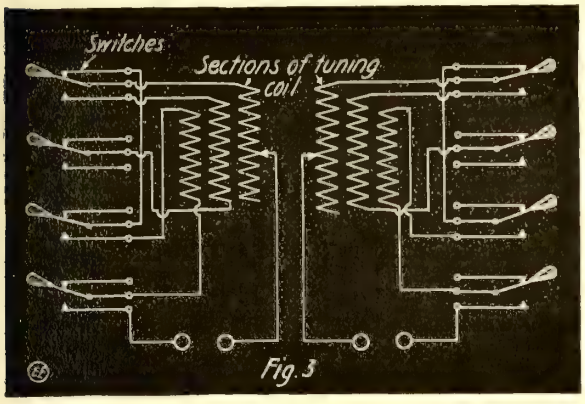

Fig. 3. Special Hook-Up of Loose-Coupler Windings to Prevent "Dead-Ends."

is about 500 feet long and averages 75 or 80 feet high.

We can hear Arlington at our station, Aberdeen, S. D., very plainly every day at this time of year unless there are unusual conditions, and are now doing most of our receiving by day. We can also hear Springfield, Ill., send out the time nearly every day at noon, and usually it comes in quite loud. We are unable to hear Key West, or San Diego or Mare Island on the Pacific Coast at this time of year, but we very often heard them in the daytime when they sent out the time during the winter.

The photo of tuning coil is not very good and does not show it as we would like. Also there will be seen a coil lying on top of this coil or tuner, and a condenser forming a separate circuit that has nothing to do with the tuning coil proper and should have been left out of the picture. When the static is extremely severe we couple the tuning coil so loosely that no signals at all come through, then we tune in this extra coil and condenser to the wave length, and by tipping it slightly to one side it forms the coupling between the primary and secondary of the tuning coil, enabling us sometimes to read messages that otherwise are drowned out by static.

[*Editor's Note.*—A resistance of 9,000 ohms has been found very good for the iron wire core impedance coil linking up the two audion detectors in diagram Fig. 1.]

WHY SAYVILLE RADIO STATION WAS CLOSED.

(*Continued from page* 210.)

apparatus here shown working at full activity and when hooked up with his super-sensitive, special type, microphonic amplifier in conjunction with the Armstrong Audion circuits the signals are so loud that one can hardly stay in the room while they are "coming in" through the loud talker horn shown at the right of the picture. When the wireless room windows are open signals have been heard 600 to 700 feet away very clearly innumerable times. Mr. Apgar is certainly to be congratulated on his excellent work. Thus the experimenter comes into his own.

OUR SUPPLEMENT

THE supplement accompanying this issue of the *Electrical Experimenter* shows the working drawings for the construction of an improved type wireless loose coupler, capable of tuning in messages up to 4,000 meters wave length, when used with an aerial at least 80 to 100 feet long, comprising four to six strands, spaced three feet apart and elevated 75 to 80 feet above the ground. With larger aerials, of course, much greater wave length ranges are available with this instrument.

The drawings explain themselves and we will cover the principal points involved in making the coupler briefly.

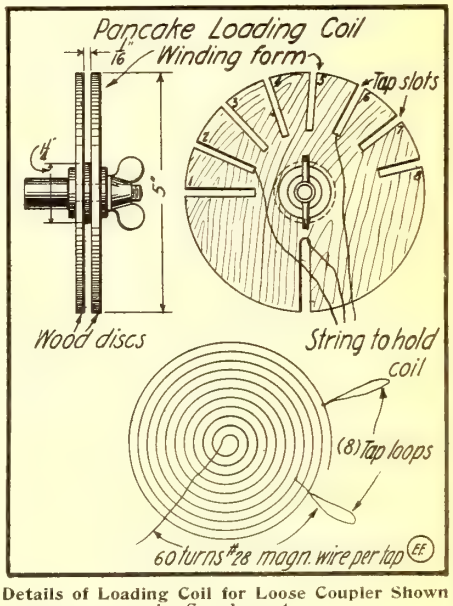
The primary and secondary coils are provided with tuning switches instead of sliders, in accordance with the best practise now followed in building such apparatus, and thus positive contact is always assured throughout these circuits. Each winding consists of one layer of wire, wound on evenly, and the taps for the various switch points are provided for while winding the coils by simply leaving a loop in the wire and twisting this loop so that it will hold itself in place. The taps are evenly divided as regards the total turns on the coils with respect to the secondary winding. In the primary coil one blade of the switch has its points connected up to successive individual turns; while the second blade of the switch controls grouped units of turns, which units are equal in number of turns.

The construction will be grasped by looking at the drawings closely; full detailed figures are not suggested for the reason that most everyone will make up the cabinet to suit himself from materials at hand. This coupler may be made larger or smaller, as preferred.

The primary interpolating switch is simply constructed and the smaller knob on same is joined rigidly to a movable center shaft which is insulated from an outside hollow shaft, and in this way two circuits are carried up through the central "combination" switch post.

A loading coil is suggested to be used with this coupler, although it is not absolutely necessary, excepting for tuning in wave lengths above 1,500 meters. This is shown in the drawing herewith, as are also details of wood or fiber form, on which to wind it.

There are eight tap leads brought out from the loading coil and equally divided, as perceived. This includes the starting and finishing leads from the coil; the wire is simply looped out successively through one of the slots as the coil is wound, in order to provide for the eight tap leads, which connect to the loading coil switch points on the hard rubber switchboard front of the primary cabinet of the coupler. The loading coil is made very thin, as will be noted, so as to give it the well known "pancake" coil effect, which is very desirable in wireless circuits; a thick coil of this type is not recommended.



Also in winding such a coil as this for wireless circuits care should be taken to "cross over" the turns or "stagger" them as much as possible and not to keep them even, as in winding magnet coils. This is done to minimize the effect of distributed capacity between turns.

A word of caution to those making such instruments as this with tap leads brought out along the coils should be noted, and the point in mind is this:

Such tap leads should in every case be short-circuited at their twisting point where they leave the coil, so that when a number of sections of such a winding are in use the current will not have to pass through one section out and around through such a tap lead or loop, back to the next section. This would greatly reduce the efficiency of the coil. Therefore the wire lead should have its insulation scraped off about ¼ inch from the winding layer proper, and preferably this point on the lead should be soldered. For those making use of Audion or Fleming valve detectors, which are potentially operated, it is best to wind the secondary of the coupler with much finer wire, say No. 30 or 32 B. & S. gauge. Some writers recommend as fine as No. 36 wire for such detectors, but it is doubtful if the damping and resistance (which are directly related) do not reduce the efficiency of the circuits of the coupler, and that the gain created by using a greater number of turns of fine wire to increase the secondary coupler potential is not off-set by the high "damping" value of the circuit. This can be experimented with, of course, by the operator making use of such apparatus.

Regarding the secondary, spring contacts are arranged inside the secondary form and which make contact with the two slider rods, upon which the secondary moves back and forth, and in this way current is carried in to and out of the secondary winding.

The arrangement shown for the secondary switch will be found very efficient and handy indeed; also this one switch knob will serve two purposes, viz., to adjust the inductance value of the secondary, as well as to vary the coupling or distance between the primary and secondary windings, by moving the secondary in to and out of the primary in the usual way.

Details of Loading Coil for Loose Coupler Shown in Supplement.

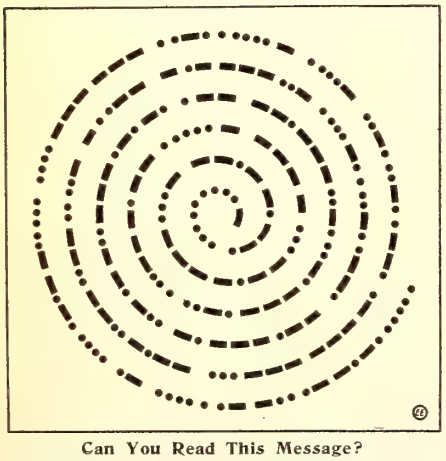
INTERESTING NEW INVENTION

A door-knob connected with an electric lamp that may be switched on by pressing a button has been patented by a New York inventor. The invention is expected to help materially in the sometimes difficult process of finding the keyhole after dark. The door-knob is illuminated. The same principle is applied to the doors and dials of safes.

AERIAL WIND STRESS PROTECTION.

Considerable trouble is encountered by amateurs utilizing trees for their aerial supports, by the breaking of the aerial wires, when the wind blows.

Balance "Strain" Weight for Tree Aerials.



The common method of overcoming this is to allow considerable slack in the wires, which decreases the efficiency and also gives the aerial a saggy appearance.

However, in the illustration herewith given is shown an easier way of eliminating this disadvantage, which will keep the aerial tight at all times, regardless of how strongly the wind blows or how much the tree sways.

A pulley is hung loosely on a limb at the top of the tree and a small rope run through it to the aerial spreader, the other end of the rope being fastened to a post on the ground, 20 or 25 feet from the base of the tree.

A 50-pound weight (a railroad iron is suitable) is attached to the rope, as described, and perfect protection is now insured against snapping wires. Contributed by ARTHUR DARLING.

HOME-MADE LIGHTNING SWITCH.

The high price of lightning switches prevents many wireless amateurs from protecting their homes or wireless stations properly. The one here described is cheap, well-insulated and capable of carrying 100 amperes.

The switch base is made of well-seasoned wood, 14x3x1½ inches. The jaws and switch lever are made of strip brass or copper, 1 inch wide and ⅛ inch thick. The lever is 8 inches long, constructed as shown in Fig. 1. An ⅛-inch hole is drilled ½ inch from the end, while the other end is twisted by placing in a vise, so as to make a handle 2 inches long. The jaws are built as shown in Fig. 2, standing 2 inches high with 1-inch flanges. A piece of brass 1 inch square and ⅛ inch thick is placed between the jaws to properly space them, and also to stop the lever in the proper position. An ⅛-inch hole is now drilled through the jaws and a piece of strip copper or brass, ½ inch from the bottom, and a rivet inserted and upset.

The jaw holding the lever is made similar to the above, with the exception that the hole is drilled ½ inch from the top instead of the bottom; no piece of strip copper being inserted between the jaws, the switch lever taking its place.

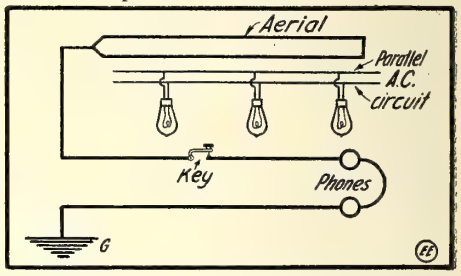
To insulate the switch properly two 6-inch porcelain tubes are used. Holes are bored a little larger than the diameter of the tubes, 1 inch from the ends of the base, and the tubes are slipped through and wedged. Four standards are now made upon which the ends of the tubes are clamped with heavy copper wire and the

Home-Made Lightning Switch.

standards are now screwed to the side of the house or shop, convenient to the lead-in wire. If the switch is not protected normally from the weather, it should be covered with a box. Contributed by ARTHUR DARLING.

SOMERVILLE, MASS., BOY RADIO OPERATOR.

The management of the Hotel Thorwald, Gloucester, is much pleased with the work of one of its employes, Willis Herbert Farnum, who has installed a wireless station there which allows the guests the privilege of receiving wireless messages of all the latest news, including sports, war news, movements of vessels, weather reports and the correct time. The station is in touch with stations as far north as Halifax, N. S., and as far south as Key West, Fla. Mr. Farnum has been an interested student of wireless telegraphy for several years, and is now gaining considerable fame as an expert operator.



NAVY ENLARGING WIRELESS STATION AT NEW ORLEANS.

Work on enlarging the naval radio station at New Orleans and installing more powerful instruments is nearing completion.

As rebuilt the New Orleans station will be the second largest of those owned by the Government. It will have a power of 30 kilowatts against the five of the original plant, and will be used principally as a relay for messages between the Atlantic and Pacific Coast stations and, when necessary, for communication with Panama.

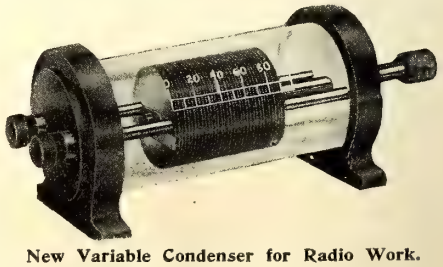
A BATTERYLESS CODE TEACHER.

Having an aerial parallel to the A. C. electric light wires, I hear a steady buzz, when the phones are connected in series

Code Learning by Induction Current from 110 Volt A. C. Circuit.

with the aerial and ground, and have used it to advantage, as shown in the diagram, to practise the code. No buzzers or batteries are needed.

Contributed by R. SHANAHAN.



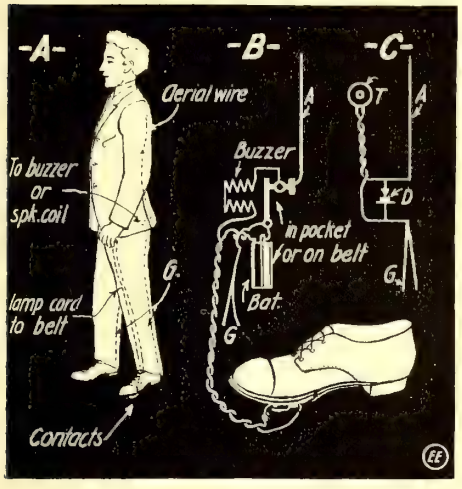
NEW HIGH POWER GOVERNMENT RADIO.

The Navy Department is planning to construct a new high power radio station on Puget Sound, probably at Keyport, near Bremerton, Wash. The plant will be one of the most modern stations ever built and will have towers 400 feet high. It is also reported that another wireless station will be erected on the Vopper River Flats at Cordova, Alaska.

A NEW RADIO VARIABLE CONDENSER.

A new variable condenser, which works different from any of the other condensers on the market, has been invented by Eugene Turney, the originator of the Crystaloi detector.

The photograph herewith illustrates the complete condenser, which consists virtually of 35 circular aluminum plates, supported on two rods, one of which is half insulated, and which are enclosed in a glass cylinder. On each side of the plate is an insulated washer, and the plates are alternately arranged on the rods so that when they are moved by means of a small handle, as shown, one plate will make contact with one rod, while its adjoining plate makes contact with the other rod, and so on. In this way the plates are varied just by pulling them in or out and consequently vary-



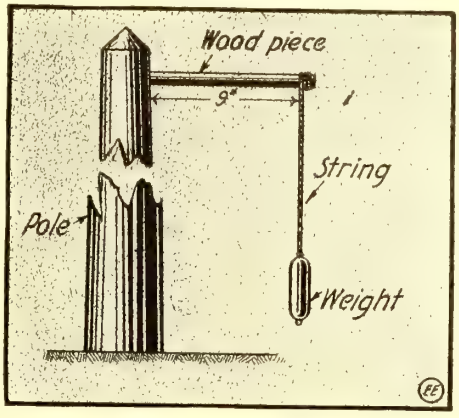
New Variable Condenser for Radio Work.

ing the capacity. When they are fully in, the capacity is at zero; as the plates are not then connected to the metallic rods, since one of them is half insulated, therefore that portion is at the end.

With such a condenser short circuits are eliminated, which is the main difficulty in the present rotary variable condenser. Two types of such condenser are now being marketed, one of 35 and another of 50 plates.

WIRELESS AND MIND READING.

MANY acts before the public profess to transmit mind waves by mental telepathy, but whether they do or not is always the debatable question. However, for the parlor entertainer it is a very simple manner to carry out such an act with the aid of a miniature wireless outfit carried on the person. For ordinary distances up to 50 or 75 feet and more, a buzzer of ordinary type will serve as the transmitter, excited by a flashlight battery, and both carried in the pockets or on a belt. Down the leg is run a 2-conductor cable of lamp cord connecting to the battery and buzzer as seen at Figs. A and B. For aerial and ground a piece of lamp cord or high tension cable is carried up the back under the coat and down the pant leg as shown. No danger whatever is present from accidental shock, etc., with a buzzer, but for the most reliable work in the largest auditorium, a small spark coil of ⅛ to ¼ inch spark capacity, should be used. A ¼ inch coil can be run, for instance on 1 or 2 dry cells of flashlight battery, so as to keep the power down. In this case, extra heavy high tension cable must be used for aerial and ground. The coil or



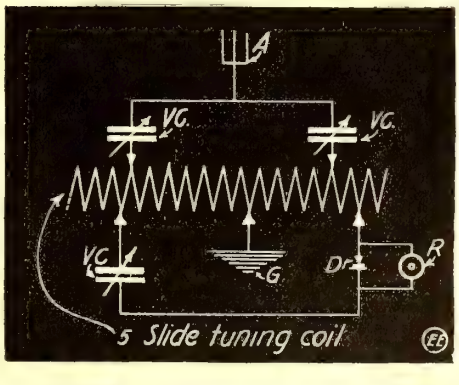
Wireless for Fake Mind Reading Act.

buzzer circuit is closed thru contact pieces of brass secured under the sole of the shoe. The receptor comprises a detector (preferably a Radioson or other constantly adjusted type), and a wireless receiver T, (1,000 ohms resistance is best). The regular telegraph code is used and by learning this, both parties can work together nicely. It works out like this: A common act is that where a gentleman goes about the auditorium or parlor asking each person the name of the song they desired played by his accomplice on the stage, who is usually a lady, who can easily cover over the telephone receiver with her hair without exciting suspicion. Now most "sharpers" who see such acts at once deduce that all of the gentleman's queries are keyed by the way in which he expresses each request of his accomplice or rather by the juxtaposition of certain words in the query. This is a common scheme long used for the purpose, but to-day something better is required in high grade entertainments. Hence with this wireless scheme, the speaker has them all guessing because each request can be stated in exactly the same way and tone of voice. For instance, "Play this gentleman's selection," etc., and this same line can be used right along, changing it to suit when referring to a lady, of course. It is usual to number the songs for such an act and then the "wireless actor" simply has to transmit the number to his assistant on the stage. For example, if "Annie Laurie" was No. 17 on the *made-up list,* then 1 and 7 in code are transmitted via radio, 1 being equivalent to dot, dash, dash, dot, and 7 to dash, dash, dot, dot. By knowing the code, the name of a song whispered to the gentleman can be transmitted if perchance it didn't happen to be on the numbered schedule. A quenched spark gap should be used on the spark coil to eliminate the noise, and the buzzer or the coil must be specially built or well muffled to prevent the vibrator hum being heard by the auditors.—H. W. S.

HOW TO PLUMB AN AERIAL MAST.

To plumb a mast fasten to the top of it a piece of wood projecting out about 9 inches. Suspend to this a window iron or other weight by means of a string, bringing the

Plumbing an Aerial Mast.



weight near the ground. Now adjust the pole on parallel with the weighted string, allowing 9 inches between them, thus creating a perpendicular pole.

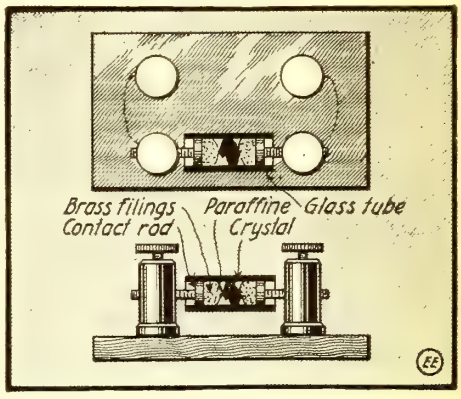
WALTER FRANSEEN.

ELIMINATION OF INDUCTANCE DISTURBANCES.

A clever method has been suggested and found to be successful in practise for the elimination of sounds in wireless telephone receivers produced by neighboring power lines. This method is depicted in the drawing, which is self-explanatory. A five-slide tuning coil, three adjustable condensers, detector and telephone receivers are necessary. Probably a three-slide tuning coil will fulfil the purpose if the end connections on the coil are used in place of two of the sliders However, the five sliders give a wide range of adjustability which allows of some wonderful tuning possibilities, including the tuning out of unwanted radio signals. It may be found somewhat difficult at first to manipulate the five sliders, but a little practise will soon familiarize the operator with the best methods to pursue.

Contributed by F. KANÆ.



A Five-Slide Tuning Coil Proves Highly Selective.

A "PERMANENT" WIRELESS DETECTOR.

No doubt many an amateur has gazed at the advertisements of "Permanent" detectors and wished he possessed one of these *wonders* that can neither be knocked out, burned out nor kicked out, and that eclipses all others in sensitiveness. But usually the price is a little "steep."

The detector I shall describe *is* permanent, and it takes a stronger-than-usual current to burn it out. The sensitiveness all depends upon the construction.

Select a piece of thick annealed glass tubing (such as water gauge tube) with a bore of ¼ inch. The tube should be 1 inch long. Get a piece of galena that will closely fit into the tube. This galena must be *sensitive,* and with as many sensitive spots as possible. I remember breaking up several ounces of galena before I found the piece I wanted. Slide this crystal into the middle of the tube and seal it in place by letting a little red sealing wax run in along the inside of the tube from both ends. A candle is very good for this operation. But be sure that the crystal is *not* covered up. There should be at least ⅛ inch of open space on the crystal at each end, and these two spots *must* be sensitive, which means a nice place for trouble if they are not. Take a pin and cut off the wax evenly all the way around the inside of the tube (see drawing).

Permanent Detector Easily Made.

Next, some metal (brass) filings are filled in at each end, making contact with the crystal, and the contact rods are pushed in after the filings. These contact rods are common switch points with the heads filed down to fit the tube. These rods fit into two binding posts as per drawing, which completes the working parts. The whole is then mounted on a base with two other binding posts for connecting to the circuit.

It will take a little time and patience to test out the crystals and assemble the detector, but once in operation it *stays* in operation. Drop it on the floor, sling it around, shake it! So long as you don't hit the tube with a hammer the detector remains as good as ever.

If no suitable galena can be found silicon can be used.

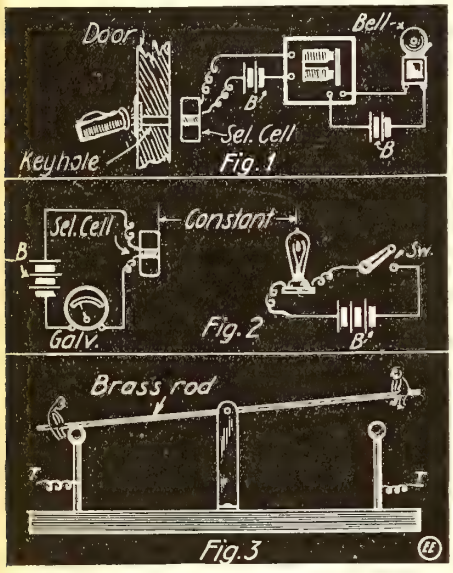
EARL H. SWANSON.

HOW-TO-MAKE-IT DEPARTMENT

This department will award the following monthly prices: FIRST PRIZE $3.00; SECOND PRIZE $2.00; THIRD PRIZE, $1.00.
The idea of this department is to accomplish new things with old apparatus or old material, and for the most useful, practical and original idea submitted to the Editors of this department, a monthly series of prizes will be awarded. For the best ideas submitted a prize of $3.00 will be given; for the second best idea a $2.00 prize, and for the third best a prize of $1.00. The article need not be very elaborate, and rough sketches are sufficient. We will make the mechanical drawings.

FIRST PRIZE $3.00.



A FEW ELECTRICAL KINKS.

Two Uses of a Selenium Cell.

To make a selenium cell burglar alarm: Place the cell (Fig. 1) inside the keyhole of door or safe and connect with bell and battery, using a relay. When burglar flashes lamp the cell closes relay, which rings bell in local circuit.

Using a selenium cell to test candle power of lamps: Connect as shown in Fig. 2, using same voltage each time. Use a galvanometer, which can have its scale specially calibrated. The meter may be calibrated by using lamps of different known candle power.

A novel static see-saw is illustrated herewith and can be worked on any Whimshurst machine. Connect the two chains T T to

Some Handy Electrical Kinks.

the poles of the machine and start the see-saw. The action is simple. The one pole attracts the brass rod and then repels it, the brass rod being charged with electricity. This is distributed all over the surface and is attracted by the other ball, and so on. Small and very light cardboard figures may be mounted on the ends of the rod. Brass balls can be tried on the rod, placing them opposite the fixed balls.

Contributed by EARL DIETRICH.

HOW TO DO SOLDERING.

Although soldering is not under the head of electricity, it is so closely allied to electrical work, not only in practical but experimental and wireless work, that any information on it ought to be welcomed by readers of this magazine who still twist their wire tightly and expect to get a *perfect,* low resistance joint.

To heat the soldering iron you will require a stove or fire, but the best and most convenient method is to use a Bunsen gas burner. A wire support for the iron should be made as suggested in the sketch.

The "dip" solution may be made by dissolving zinc in muriatic acid until it is completely "killed" or ceases to bubble, and then diluting the acid with about five times its volume of clear water. This is poured in a porcelain or glass container and is kept handy near the burner for convenience.

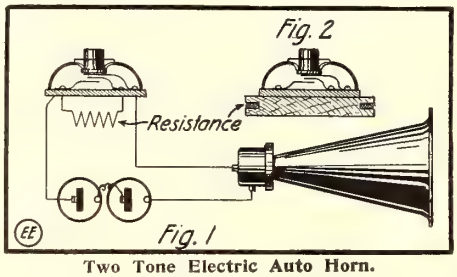
The flux should by all means be non-corrosive; tallow is as good a thing as can be obtained, although hard to work with. There are many preparations on the market that are good (as Solderall, No-corrode, etc.), and it is very much easier and cheaper to buy a small can of some reliable make. By all means use soft solder; wire solder fills every demand.

Essentials of a Soldering Outnt.

Light the burner and adjust it till it gives a clear, blue flame, and lay the iron on the support so it is in the upper or hottest part of the flame. Meanwhile clean the parts to be soldered and give them a thin coat of flux. *Remember, metals MUST be bright and clean, else the solder will not "flow."*

When the iron is hot enough (not red hot) dip it for an instant into the "dip" solution, then touch it to the solder and give it a good coat. This is called *tinning.* The parts should now be tinned by passing the iron over them, then press together and rub iron on top, resulting in an electrically perfect joint. Be sure the solder flows evenly and smoothly through the joint.

The iron is hot enough when green flames are seen around its edge, and it may be necessary to file a clean surface on it if it gets red hot, as this burns the solder off. In closing, I repeat: Always keep the iron well tinned and the parts well cleaned, and success will invariably follow.



Contributed by THOMAS W. BENSON.

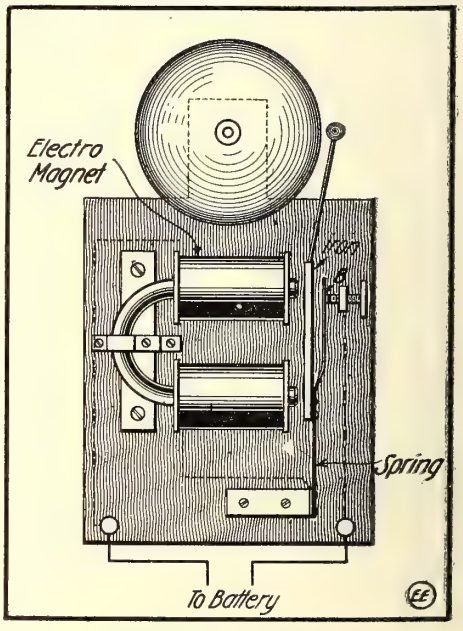
SECOND PRIZE $2.00.

A DOUBLE-TONE AUTO-HORN.

By inserting a little resistance in series with an automobile horn or other electric signal the tone may be lowered more or less, depending upon the amount of resistance set into the circuit.

Oftentimes it is very undesirable to blow an auto horn while passing through a town

Two Tone Electric Auto Horn.



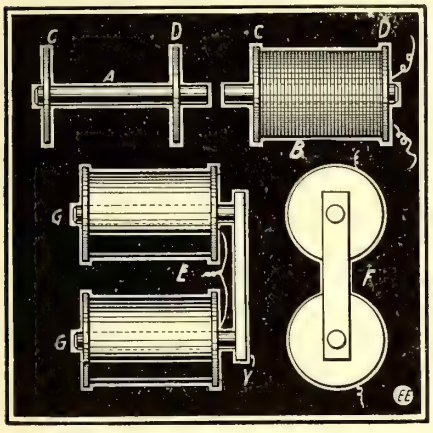
at late hours, as some electric signals are very unpleasant to the near-by inhabitants. A simple way to work the above scheme out is to make a double contact push button, which is very clearly explained in the diagram given herewith.

Two or three feet of No. 22 or 24 soft iron or German silver insulated wire will be about right for the average electric signal, such as is used on automobiles and motor boats. A very convenient place for the resistance can be made by cutting a groove in the base of the push button, as shown in Fig. 2. By pressing the button slightly the signal will sound about half tone; press the button a little harder and the signal will sound at full tone. Contributed by H. CORCELL STUART.

THIRD PRIZE $1.00.

A HOME-MADE ELECTRIC BELL.

To make a cheap yet satisfactory electric bell cut out a small board, six inches square with a one-inch square projection at one end, as illustrated. To this board screw a block of wood, 3x½x½ inches, and fasten an electromagnet to the latter, as shown. In the center at the bottom of the board attach another block, 1x½x½ inch, and to this screw a piece of clock or brass spring with a soft hammer affixed, which should be long enough to extend past the two ends of the electromagnet. On the inside of this spring rivet a small brass strip and then solder a piece of silver on it. Then bend the brass strip, as depicted in sketch. A small thumbscrew should now be attached in such



Home-Made Electric Bell.

a manner that the silver point of same touches the silver on the strip. An old bicycle or alarm bell gong is fastened by a screw to the projection at the top of the board, and the wiring arranged as per outline herewith given. We now have a complete and useful little electric bell that will be found very serviceable. If desired, two binding posts may be fastened to the end of the base. Contributed by WILLIAM WINTERS.

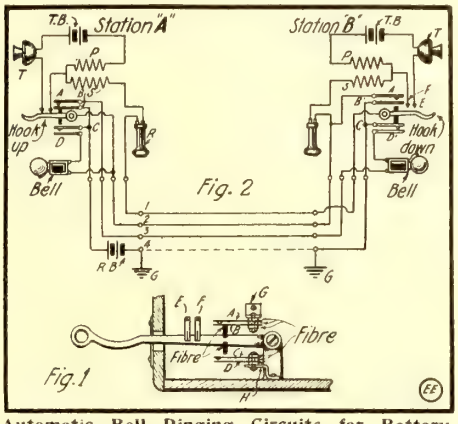
HINTS ON ELECTRO-MAGNETS.

The principle of most electric instruments, as well as machinery, is based upon the electro-magnet, for the construction of which the following directions will be found very serviceable.

First, remember that the nearer to the iron core the coils are wound, the stronger the magnet. Secondly, a magnet does not increase in strength materially after the wire is wound on deeper than the diameter of the core. That is, if a core is ½ inch in diameter it should not be wound to a diameter of over 1½ inches. If a weak current is used, wind with small wire; the less current utilized, the smaller the wire. For telegraph coils and bells use about ½ inch core 2½ inches long, and wind to a diameter of 1 to 1¼ inches with No. 24 or No. 26 copper wire. To make a single magnet, take a large wire nail or soft round iron bar 2½ to 3 inches long. Cut a circle of stiff thin wood or cardboard and, after fastening it on the bar, wind with No. 26 or 28 magnet wire, taking care not to injure the insulation. Apply a coat or two of gum shellac or dip in melted paraffine for a few minutes, and dry. Fig. A shows bobbin of magnet ready to be wound; at Fig. B it is already wound. C and D are the discs of wood or cardboard, and E illustrates a double magnet. A side view of the magnet is shown at F. The iron cores G G may be riveted onto the iron yoke Y or secured by machine screws. The yoke Y should have the same cross-sectional area

Hints on Making Electro-Magnets.

as the cores G, or even a greater area. Tapering the pole faces as shown increases the pull on the armature, as it raises the flux density at this point. Contributed by



E. THOMPSON.

STUNT FOR BATTERY TELEPHONES.

Herewith is a handy time-saving stunt for those using ordinary battery telephones.

In Fig. 1 E and F are the regular talking contact springs, E going to the transmitter and F to the induction coil, P and S, see Fig. 2. G and H are brass arms, serving as supports for the springs, A, B, C and D. These springs are made of spring brass, and are about 1½ inches long, 3-16 inch wide and quite stiff (about No. 24 gauge). The springs, A and C, have a piece of platinum wire inserted at their ends, which make contact on two pieces of platinum foil on springs, B and D. The springs A, B, C and D are insulated from each other and from their supports by means of fiber washers between them, and the whole clamped together by a screw and nut, as shown. On top and bottom of the hook saw or file out two recesses and fit into them two pieces of fiber ⅜ inch square by ⅛ inch thick. These actuate he springs A, B, C and D. The hook spring, tending to push the hook up, is not shown for the sake of clearness.

Referring to Fig. 2 it will be seen that four wires are required for a full metallic system; but inasmuch as the No. 4 wire is used for ringing only, it may be substituted by the ground as shown, the dotted line in-

Automatic Bell Ringing Circuits for Battery Telephones.

dicating the No. 4 wire if used. By following out the circuits in Fig. 2 it will be evident that raising the receiver from the hook at station A, will ring up station B, which will continue to ring until B answers his telephone or A replaces his receiver on the hook. R B is the common ringing battery for the system. Wires 1 and 2 are used for talking and wires 2, 3 and 4 (or ground) for ringing. There are no push buttons or switches to operate in this improved system, and only three wires are really necessary.

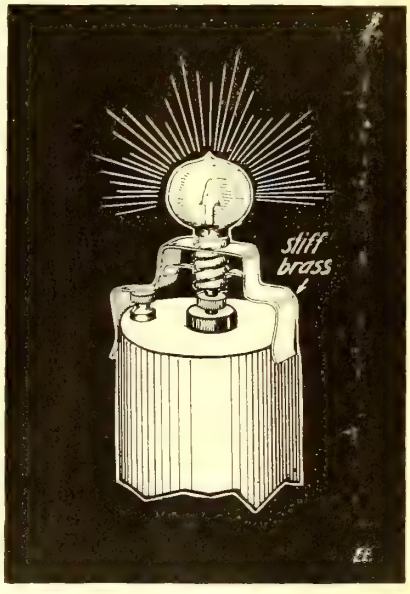
FRANK G. CASEY.

A MINIATURE ELECTRIC RAILWAY SIGNAL.

Those interested in small electric railways in miniature will probably like to construct a double lamp signal, electrically operated by a solenoid magnet, as the sketch here shows. It is very simply made and a single, low voltage battery lamp serves the purpose.

Referring to the sketch, A is a solenoid coil, corresponding to an ordinary bell magnet and inside of this a movable iron core M can slide up or down. This sliding iron plunger M is joined to a pivoted arm L. On the end of this arm is mounted a shutter H. Two small shields with



Two-Way Miniature Electric Railway Signal.

white and red glasses F and G are mounted in one end of a light-proof casing E. J is a minature lamp socket holding the small tungsten lamp, as observed. This lamp is supposed to be kept burning, while the miniature railway is in operation and the white and red or green and red signals, as desired, are shown alternately, by suitably arranged automatic or other switch contacts, to open and close the solenoid coil circuit. The solenoid may be wound with about 40 yards of No. 26 magnet wire or with a somewhat larger wire than this. Contributed by

I. WITT.

A HANDY BATTERY LAMP MOUNT.

The following is the description of a handy and simple mount for lamps. Procure a sheet of springy brass and cut a strip about 5 inches long and 1 inch wide, but leave a hole in the center large enough to admit a miniature lamp adapter. This is to be placed in the hole and supported by two pieces of brass, bent and soldered, as clearly shown in the sketch. The brass (large) strip, of course, must also be bent exactly as shown in sketch. Then, lastly, screw a lamp into the adapter and the device is ready. Snap it on to a dry cell and it is ready for use, as shown. The battery cannot be short circuited, as the brass strip is in connection with the zinc when attached and the carbon of the battery individually in connection, with the base of the lamp just protruding a little so that carbon, screw and base of lamp touch. If the light is not wanted the lamp may be

Simple Lamp Adapter for Dry Cells.

slightly turned to the right, thus opening the circuit. If battery is run down the outfit can be quickly clasped to another in three seconds.

HENRY BOWEN.

QUICKLY MADE CONDENSERS.

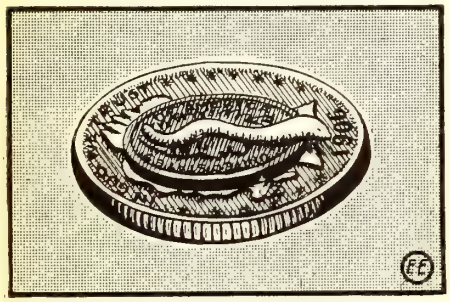
When in need of a small condenser for receiving, one can be easily made as follows:

Procure a small memorandum or notebook (such as those given away to advertise medicine, etc.) and some tin-foil. Cut the tin-foil sheets a trifle smaller than the leaves of the book and insert a sheet of foil between each leaf until the desired number of sheets are obtained to give the proper capacity, allowing the ends to protrude alternately on each side for connections.

Should a permanent condenser be required, the book containing the foil may be soaked in hot paraffine wax and pressed with weights; then mount it in a case. But for temporary use a weight placed on the book is sufficient. Contributed by

FRANK HAVERLAN, JR.

"AND THE WORM CAN'T ESCAPE!"

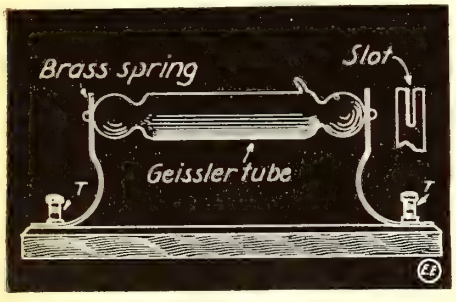


A rather peculiar experiment may be performed with the following articles, to wit: One worm (ordinary garden variety), one copper coin and one silver coin. The copper coin is placed on top of the silver coin, and it should be about 3/16 inch at least smaller all around than the silver piece. If now the worm is placed on top of the copper coin, it will be found that it cannot get off same, as every time he gets his damp body in contact with the two different coins it sets up an electro-motive force through the circuit so provided, which gives Mr. Worm, of course, an appreciable shock; so much so, in fact, that he prefers to stay on the top coin.

Contributed by G. HUGO.

[*What happens to such an experiment as this, in case the worm is kept on the top coin long enough to become thoroughly dry, the author of the experiment does not state.—Ed.*]

It will probably make the worm turn!



G. H.

The Worm Can't Get off the Coins.

A GEISSLER TUBE STAND.

Many experimenters have no doubt often wanted to know a simple way in which to mount Geissler tubes. Here is a way to mount it. Obtain a piece of wood, marble or glass. Take the brass parts from an old flashlight battery and bend them as seen in the sketch. Cut or file slots in both springs and the tube can then be snapped into place. The secondary spark coil leads

Geissler Tube Stand.

connect to the two binding posts, TT.

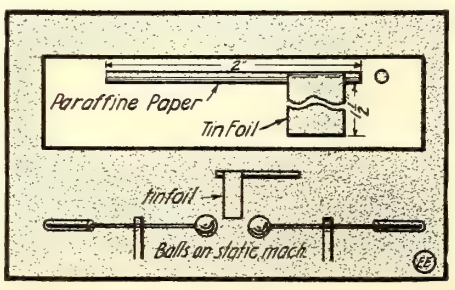
ORGANIZE WIRELESS SOCIETY AT ATLANTA, GA.

A wireless society has been organized at Atlanta, Ga., to advance the interests of wireless amateurs and is known as the Atlanta Radio Club. Communications from amateurs within 100 miles from Atlanta are solicited by the club.

Amateur operators, or those wishing to become such, are requested to interchange ideas with the members of this society. All correspondence should be addressed to M. A. Herzog, secretary, 16 Faith street. Atlanta, Ga.

A MOTOR ATTACHMENT FOR BOATS.



Attaching Small Battery Motors to Model Boats.

Toy boats, such as miniature yachts, sailboats, etc., can be electrically propelled by means of a motor acting as the chief propelling agent. Sketch at Fig. 1 shows how motor is fastened on the end of boat, and by means of its shaft and belting is propelling the vessel by turning the shaft of the propeller, fastened and supported by two wire supporters "A." For battery power a 3-volt Radio Nitrogen Battery is the choice, instead of loading the vessel with less powerful one delivering only 1½ volts or so. Two of these powerful cells will operate the motor at a terrific speed and will rapidly propel the vessel it is attached to. Paddle wheels can also be used. Two should properly be employed, and the diagram at Fig. 2 shows the arrangement for this method, if preferred. The cells of battery can be placed in the lower part of the vessel and can be controlled by a switch conveniently located. Contributed by

WM. WARNECKE, JR.

A STATIC EXPERIMENT.

Here is an experiment for static machines. Take a piece of paraffine paper about 2 inches long and roll it. On this paste a piece of tinfoil and let it hang down about 1½ inches from the paper. Now place the paper in left hand and hold over the balls on the machine. Start the static

Static Machine Experiment.

machine and then let go and watch the tinfoil fly back and forth very rapidly.

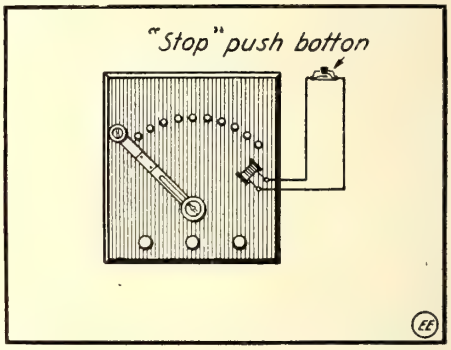
HOW TO FROST GLASS.



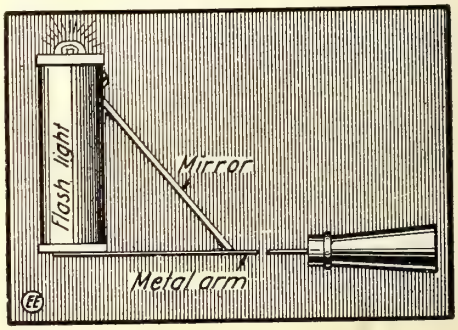
By proper chemical treatment glass electric bulbs will have the same appearance and do the same work as glass subjected to grinding.

In 2 ounces of ether dissolve 90 grains of gum sardarac and 20 grains of gum mastic. One ounce of fresh benzole is added later. The solution should be poured quickly and evenly over the surface to be frosted. Contributed by

W. WESTON.

QUICK STOP FOR ELECTRIC MOTORS.

One of the simplest ways in which to stop an electric motor employing the usual no-voltage release type starting box, is to connect a push button across the electro-magnet on the face of the box. When this push button is depressed it short-circuits the magnet coil and the arm of the starting box is quickly released, cutting off the power to the motor.



Quick-Stop Motor Control by Push Button.

This principle is used to a great extent in the various styles of push button type electro-magnetic controllers on the market.

A "WALLOSCOPE" FOR ELECTRICIANS.

The drawing herewith shows what I have termned a "Walloscope;" it will be found of great help to electrical contractors, wiremen, machinists, or in fact anyone

Wall Inspecting Lamp for Electricians and Others.

who in the course of his work finds it necessary to employ a special instrument to look into places which cannot be seen otherwise. The following device will be found very handy in such a case:

It consists of a regular small size pocket flashlight fastened on the end of a handle, which also carries a mirror, in which to view corners with, etc. Contributed by

CARL S. DRESS.

AMATEUR WIRELESS STATION NEARLY READY.

The boys of Mt. Sterling, Ill., have their wireless station about ready and expect to be able to receive messages in a few days. When this is in running order, the weather reports sent out by the Government from the Illiopolis wireless station will be picked up by them.

WRINKLES — RECIPES — FORMULAS

Edited by S. GERNSBACK

Under this heading we will publish every month useful information in Mechanics, Electricity and Chemistry. We shall be pleased, of course, to have our readers send us any recipes, formulas, wrinkles, new ideas, etc., useful to the experimenter, which will be duly paid for, upon publication, if acceptable.

EXPERIMENTERS APHORISMS.

In the following, we wish to give to the Experimenter some hints as to the use of the different ingredients and how to work them:

(1) Always bear in mind that exact working of a formula requires ACCURACY, CLEANLINESS, PATIENCE, and SKILL.

(2) Know what you are about, before you start to experiment.

(3) "THE HISTORY OF FAILURES IS THE HISTORY OF SUCCESS" goes an old adage, and it applies well to the experimenter.

(4) Many times impure, wrong or deteriorated raw materials, spell FAILURE instead of SUCCESS.

(5) A great many of the chemicals and ingredients required, cannot be obtained from drug stores; buy them at a reputable supply house.

(6) BEFORE CONDEMNING A FORMULA, be sure the fault does not lie with the manner of handling it, or the purity of the ingredients.

(7) Be sure to mix the materials comprising a certain formula in the proper sequence.

(8) When starting to prepare a mixture, especially one containing liquids, ask yourself: "IS THE SPECIFIC GRAVITY CORRECT, AS INDICATED BY A HYDROMETER? IS THE TEMPERATURE RIGHT? IS THE QUANTITY OR WEIGHT RIGHT?

(9) Acids and water, when mixed, should be manipulated in the proper manner, i. e., THE ACID SHOULD BE POURED INTO THE WATER, and not vice versa, as the solution is liable to be forcibly ejected from the containing vessel and into the mixer's face.

(10) For any kind of SYSTEMATIC WORK, a floating THERMOMETER and HYDROMETER, as well as measuring glasses and scales, should always be provided, as GUESSWORK is EXPENSIVE, and SOMETIMES FATAL.

(11) Put labels on ALL bottles, boxes and packages with FULL INSCRIPTION as to their contents, it will avoid troubles and mistakes.

(12) Remember that a beginner cannot expect to make articles AT FIRST, which will compare with regular manufactured products.

FORMULA 13.
Welding.

Welding Composition.—Dissolve in water 30 parts of *Borax,* 4 parts of *Sal Ammoniac,* 4 parts of *Cyanide of Potash.* Evaporate the water at a low temperature.

Welding Flux.—Pulverize the following ingredients: 2 oz. of *Copperas,* 1 oz. of *Saltpeter,* 6 oz. of *Salt,* 1 oz. of *Oxide of Manganese,* 1 oz. of *Cyanide of Potash.* Mix together with 3 lbs. of good *Welding Sand.*

Welding Powders.—Calcine and pulverize together 50 parts of *Iron Filings,* 5 parts of *Sal Ammoniac,* 3 parts of *Borax,* 2½ parts of *Copaiba Balsam.*

To Weld Cast Iron.—Take of good, clear *White Sand,* 3 parts; *Refined Solton,* 1 part; *Fosterine,* 1 part; *Rock Salt,* 1 part; mix all together. Take the two pieces of cast iron, heat them in a moderate charcoal fire, occasionally taking them out while heating and dipping them into the composition until they are of a proper heat to weld, then at once lay them on the anvil and gently hammer them together.

To Weld Cast Iron.—The best way of welding cast iron is to take it at a very intense heat, closely approaching the melting point. In this state it will be found sufficiently malleable to stand welding by the hammer.

Composition Used to Weld Cast Steel.—10 parts *Borax,* 1 part *Sal Ammoniac.* Grind or pound them thoroughly together, then fuse them in a metal pot over a clear fire, taking care to continue the heat until all spume has disappeared from the surface. When the liquid appears clear the composition is ready to be poured out to cool and concrete; afterward being ground to a fine powder, it is ready for use. To use this composition the steel to be welded is raised to a heat which may be expressed as "bright yellow." It is then dipped among the welding powder and again placed in the fire until it attains the same degree of heat as before. It is then ready to be placed under the hammer.

Composition for Welding Cast Steel.—Pulverize borax, any quantity, and slightly color it with dragon's blood. Heat the steel red hot, shake the borax over it; place it again in the fire till the borax smokes on the steel, which will be much below the ordinary welding heat, and then hammer it.

German Welding Powder.—4 parts *Iron Turnings,* 3 parts *Borax,* 2 parts *Borate of Iron,* 1 part *Water.*

Welding a Small Piece of Iron Upon a Large One, with Only a Light Heat.—It is often desirable to weld a small bit of iron upon a large bar, when the large piece must be heated equally hot as the small one. To save this take *Borax,* 1 lb., *Red Oxide of Iron,* 1 to 2 oz. Melt them together in a crucible, and when cold pulverize it and keep the powder dry for use. When you want to perform the operation, just bring the large piece to a white heat, having a good welding heat upon the small slip; take the large one from the fire and sprinkle some of the powder upon the place, and bring the other upon it, applying the hammer smartly, and the weld will be as good as could be made with the greater heat without the powder.

Belgian Welding Powder.—1,000 parts *Iron Filings,* 500 parts *Borax,* 50 parts *Balsam of Copaiba or other resinous oil,* 75 parts *Sal Ammoniac.* Mix all well together, heat and pulverize completely. The surfaces to be welded are powdered with the composition and then brought to a cherry-red heat, at which the powder melts, when the portions to be united are taken from the fire and joined. If the pieces to be welded are too large to be both introduced into the forge, one can be first heated with the welding powder to a cherry-red heat and the other afterward to a white heat, after which the welding may be effected.

S. G.

FORMULAE FOR INVISIBLE INKS AND SILVER PLATING.

No. 1.—20 parts water, 1 part sulphuric acid. Add the acid to the water and not the water to the acid. Unless care is taken that this is done, the heat developed by the dissociation of the acid may break the vessel. Use with a clean steel pen, and when writing is dried it will become invisible, unless the pen has scratched the surface. To read, hold the paper for a moment near a red-hot stove or before a gas flame.

No. 2.—1 oz. citrate of potash, 5 oz. water. Make a complete solution and use same as No. 1.

Sympathetic Ink.

Dissolve chloride or nitrate of cobalt in water. When warmed slightly before a fire the writing will show; on exposure to moist air it will disappear.

Silver-plating Fluid.

One oz. silver nitrate, 12 oz. rain water. Dissolve and add 2 oz. of potassium cyanide. (The latter should be carefully handled, as it is poisonous.) Clean the article thoroughly and apply the fluid by rubbing. The fluid may be used on detector parts, but as the deposited film of silver is not very substantial it would not do for articles which are to be continually carried in the pocket, etc. Contributed by

A. D. R. FRASER.

Why not subscribe to-day? Don't miss the many good articles in store for you.

REGARDING WOOD STAINS, ACIDS AND INVISIBLE INKS.

I wish to call your attention to the invisible ink recipes on page 100 of the July, 1915, issue by Mr. K. K. Knaell, particularly to No. 3. I have used with very good success a formula composed of 50 grains of chloride of cobalt, 1 ounce of water and 10 minims of glycerine; the latter being added to give body to the writing fluid. I think if the formulas mentioned by Mr. Knaell had this addition the writing quality would be increased.

The Proper Use of Sulphuric Acid.

This article is written for the benefit of amateur electrical and wireless experimenters as well as those interested in chemistry, not familiar with the dangers which may arise if sulphuric acid is not properly used.

Sulphuric acid is chiefly used in electrical experiments in the construction of electrical batteries. It is commonly and commercially known as "sulphuric acid," but there are other names under which it is termed and sold, i. e., "hydrogen sulphate," "hydric sulphate," "oil of vitriol," etc.

It is a thick, heavy, oily, sour and corrosive liquid, and in its pure state is without odor or color. It boils at 338 degrees and freezes at about zero.

The fact has been repeatedly illustrated in experiments already performed that sulphuric acid has a very strong tendency to absorb water and form compounds with it, thereby causing great heat to be formed in this action, and attention is called to the necessity for caution in mixing the liquid.

ALWAYS POUR sulphuric acid IN SMALL QUANTITIES INTO the water while stirring the same VIGOROUSLY. It is also well to work with such chemicals as sulphuric acid, nitric acid, hydrochloric acid, etc., where a draught of air can be created to prevent the poisonous fumes from being inhaled into the lungs.

Wood Stains.

To stain ebony, mix: Solution A—Water, 10 ounces; sulphuric acid, 1 ounce. Brush on and allow to sink into the wood to be stained, and then hold close to a fire for a few minutes, in which time a rich black is produced.

Solution B—Strong solution of aniline in alcohol or French polish.

To Stain Walnut.—Potassium permanganate, 60 grains; water, 10 ounces. Used weaker it imitates oak.

To Stain Green.—Solution A—Verdigris 4 ounces; vinegar, 40 ounces. Solution B—Indigo, 1 drachm; vinegar, 20 ounces. Boil each for 10 minutes. Mix according to tint. Average proportion: (A) 6 ounces: (B) 1 ounce. Contributed by

A. WILSDON.

WIRELESS PLANT BASIS OF SUIT.

Vice-Chancellor Stevens, in an opinion filed in the Trenton, N. J., Court of Chancery Aug. 2 last, denied the application of a German corporation for the postponement of the hearing and determining of a suit brought in the Court of Chancery of New Jersey by a French corporation to compel the German concern to carry out an alleged contract to dispose of its wireless telegraph station at Tuckerton, N. J., to the French corporation.

The Germany company in its answer to the suit denied knowledge of the contract and asked that a hearing and determining of the case be deferred until after the close of the present war.

The name of the German company is the Hoch Frequenz-Maschinen Aktien-Gesellschaft für Drahtlose Telegraphie of Berlin. The French corporation is the Compagnie Universelle de Télégraphie et de Téléphon sans fil, with offices in Paris.

AMONG THE AMATEURS

AMATEUR RADIO STATION CONTEST.

Monthly Prize, $3.00.

This month's prize winner.

PAUL SHNEY'S AMATEUR STATION.

The following is a description of my radio receiving station:

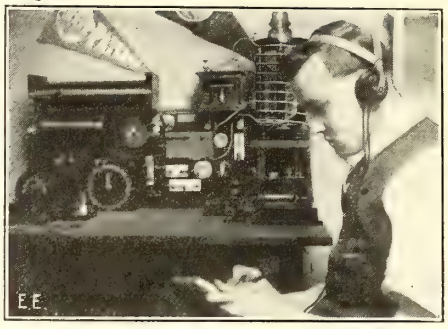
Receiving—A home-made duplex loading coil with primary slider and secondary switch with seven points, a loose coupler, a variable and fixed condenser. For convenience in quickly changing from long to short wave length, and vice versa, the switch at the left of the loose coupler is used to short circuit either the primary of the loader or the series condenser. A 3-point detector switch is used to connect at will a Radioson detector, a silicon or a galena detector. The operative detector is connected in series with a "junior" fixed condenser. The "junior" condenser is bridged by two 1,000-ohm receivers in

Paul Shney Enjoys to the Full His Excellent Wireless Set.

series, while the ½ M. F. condenser is bridged by two watch case receivers in parallel. Some wires connected to the other leads enable four people to hear at once, and are also used as a buzzer telegraph line for experimental purposes. The switches and rheostat at the bottom of the board are used to control these circuits, as well as the coherer and polarized relay for audible reception of signals.

My aerial is 125 feet long and spaced 2 feet 8 inches apart. Iron pipe spreaders 11 feet long are supported at the upper end to the roof of a three-story hospital. The maximum wave length of primary and secondary are each about 5,000 meters. Weather conditions prevent me from hearing WSL and NAA occasionally.

PAUL F. SHNEY.



Pittsburgh, Pa.

The United States navy will establish a wireless station on Cape Cod especially equipped to guide vessels along the Atlantic coast in time of fog.

Within a few months wireless messages have been sent from a station in this country to Paris. They are sent direct and not relayed from ships.

A SUCCESSFUL RADIO STATION.

Herewith will be found a photograph of my radio laboratory which I wish to enter in your contest. As you will notice, the set is practically all home-made, but I get excellent results. I am now experimenting with a one-wire antenna 150 feet long and 65 feet high at one end and 80 feet at the other.

Harold Mason at His Radio Set.

For sending I use a 2-inch spark coil, operated on dry cells, helix, adjustable plate condenser, "Electro" vertical gap inclosed in cabinet and key. I have a small medical coil with which I can send short distances. I have also a complete buzzer test in circuit.

For receiving I have one large single slide tuner, one loading coil, receiving transformer, pancake tuner with 25 taps, one "Electro" fixed condenser, one mineral detector for galena, silicon or iron pyrites and one head set of 1,000-ohm receivers.

I hereby wish to state that I agree with other amateurs that galena is the best of all minerals in use.

Paterson, N. J. HAROLD MASON.

HAROLD BENNETT'S WIRELESS PLANT.

I give you herewith photo of my wireless set, which I should like to appear in your magazine. Starting from the left will be observed my receiving set, which consists of one loading coil, variable condenser, fixed condenser, a galena detector, tuning coil and a pair of 2,000-ohm 'phones. In my sending outfit I use a ¼-inch Bulldog spark coil, two glass plate condensers (home-made), one large helix, spark gap, key and double throw switch. The latter articles are all home-made.

My aerial is built on top of a school building and I can receive up to 1,000 miles and send about four. I can hear (I. W.

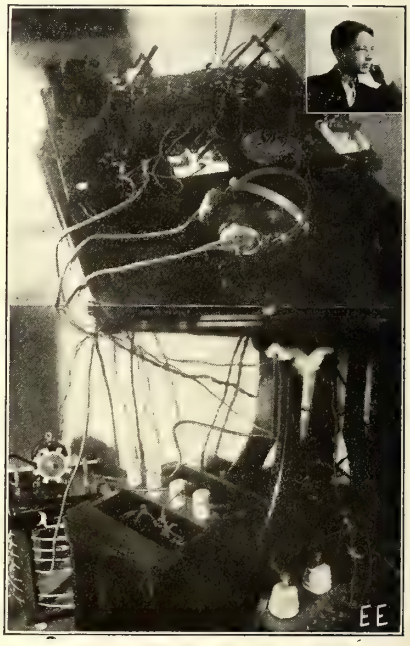
Harold Bennett's Radio Station.

Co.) Illinois Watch Co. very clearly.

HAROLD BENNETT.

Clarinda, Iowa.

DONALD HOFFMAN'S WIRELESS OUTFIT.



Your last few issues of the *Electrical Experimenter* have made it my favorite electrical magazine. Perhaps its readers will be interested in a brief description of my wireless station.

Sending set: Packard ½ K. W. transformer, home-made glass plate condenser connected series-parallel, rotary spark gap, home-made oscillation transformer, key, switches and rheostat.

Receiving set: Selective coupler, Blitzen loading coil, rotary variable condenser across secondary circuit, Brandes' 2,000-ohm receivers, Crystaloi detector and buzzer test, galena detector and small fixed condenser in shunt with receivers.

I have two aerials of copper-clad wire, both well insulated and provided with proper lightning switches and ground wires. The small aerial is "L" type with four wires, 57 feet long and 30 feet high and is used for sending. The large one is of the "T" type with two wires, 210 feet long; both aerials used for receiving.

I also have wire connection to another

The Efficient Radio Outfit of Donald Hoffman.

boy's house, two blocks away, over which we conduct numerous experiments in wireless, telephony, telegraphy and other forms of communication.

The local amateur and commercial stations all come in fine, as do Arlington, Sayville, Detroit, Cleveland, Canton, Key West and others. Extension receivers and buzzer test control in my bedroom enable me to listen in at any time I care to.

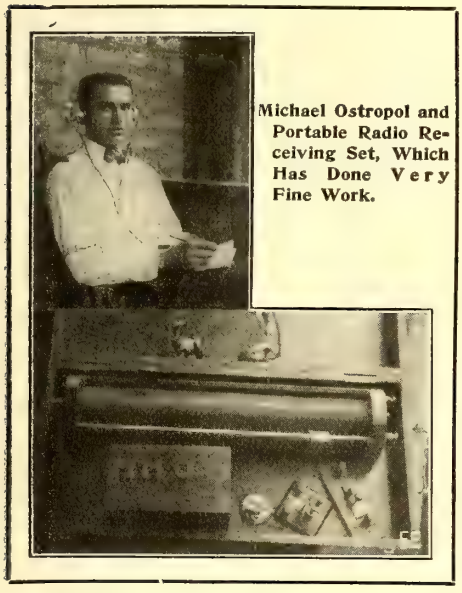
The outfit is mostly all on or under a table, easily accessible, and in as small a space as possible. All wiring and other work of this nature was done by myself, including the electric-light wiring, which was necessary in order to use the transformer outfit. I keep wireless maps, photos and wiring diagrams posted on the wall for instant reference by myself or visitors. I have a Government license and an official call, "8 A.D.U."

DONALD HOFFMAN.

Akron, O.

"THE AMATEUR SCIENTISTS."

A new wireless association known as "The Amateur Scientists" was organized a short time ago and constitutes the following members: J. G. Dashafsky, W. Wernick, O. Dubs, E. Duskis, H. Fienberg, A. Feldman and S. Bosowitz.



The purport of this society is to make the acquaintance of young scientists and people scientifically inclined. All communications should be addressed to Ephraim Duskis, press agent, 1423 St. Marks Ave., Brooklyn, N. Y.

OSTROPOL'S RADIO STATION.

The accompanying photograph portrays my radio receiving (portable) station, which I constructed myself and from which very successful results are obtained.

This set is composed of a double slide tuner, 20 inches long and 4 inches in diameter, wound with No. 20 enameled copper wire, a variable condenser, two crystal detectors, a test buzzer and two 3,000-ohm head 'phones. This outfit is mounted in a highly polished oak cabinet 22 inches long, 11 inches wide and 6 inches deep, which opens by means of folding doors. Four binding posts, two on each side of cabinet, enable me to operate the set without opening the doors.

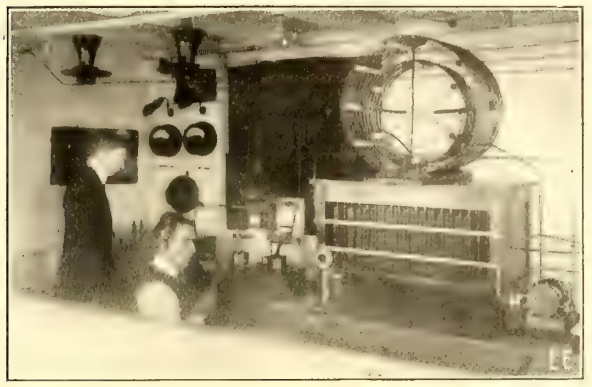
I wish to say that I have gained most of my ideas from the *Electrical Experimenter*, of which I am a constant reader.

Michael Ostropol and Portable Radio Receiving Set, Which Has Done Very Fine Work.

MICHAEL OSTROPOL.

Chicago, Ill.

JEANNETTE, PA., BOY WIRELESS OPERATOR ON THE TEXAS.



Relatives have received word from Simon J. Murphy, a popular young man of this town, telling of his successful appointment as wireless operator on the United States dreadnaught "Texas," and of the aquatic maneouvers of that huge fighting vessel of Uncle Sam's navy in Gulf waters.

"We are en route South for maneouvers and target practice; thence to Mexico, it is believed. Everything looks very encouraging to me, and my chances to become a 'radio gunner,' as it is termed, are very good," he said.

Young Murphy received the appointment recently and is in full charge of the "wireless room." He is a graduate of the United States navy electrical school.

A SUCCESSFUL WIRELESS TELEPHONE AND TELEGRAPH STATION.

The accompanying photograph shows Earl Hanson and Hadys Hancock operating the private wireless telephone and telegraph station on Venice pier, California.

Wireless Telephone and Telegraph Station of Earl Hanson and Hadys Hancock.

On the table at the left and under the switchboard is shown a mahogany case containing the wireless telephone apparatus. Among the various systems tried the 60-cycle arc gives all around results and holds up under long tests. It may be well to say here that much value has been derived from your articles on wireless telephony appearing in the *Electrical Experimenter*.

Above the switchboard can be seen the large high-tension insulators connecting the aerial lead to the transmitting set. This consists of a 5-kw. closed core transformer, but to conform with the radio law only 1 K.W. is used. A large glass plate condenser and an inductance, together with a high-speed rotary gap, giving a high note, easily read through interference, completes the set. The connections throughout the station are of large brass and copper tubing, giving the minimum high frequency resistance.

In the center of the photo, just below the aerial switch, is depicted the latest type receiving set. The aerial, made of E. I. Co. stranded "Antenium" phosphor-bronze cable and situated on the pier, is 300 feet long and 100 feet high. With the ocean for a ground, surprising receiving distances are accomplished. Nature also helps here, for the Pacific coast is not so heavily charged with the static that is encountered on the Atlantic seaboard.

EARL C. HANSON.

Los Angeles, Cal.

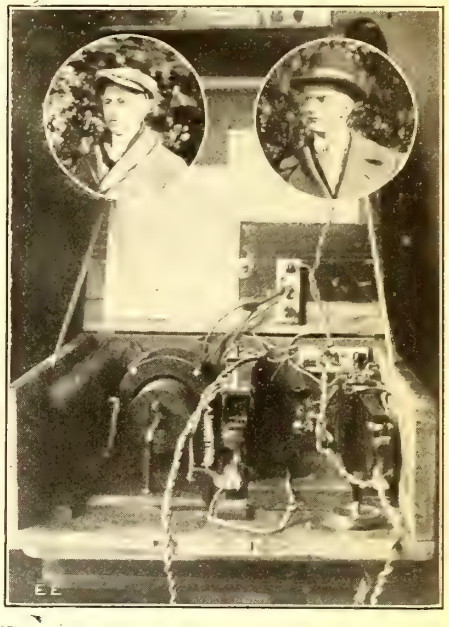
RADIO EQUIPMENT OF HUBERT M'ILVAINE.

Herewith is a photo and description of my wireless station. The sending outfit consists of a 1½-inch spark coil, home-made condenser of photo negatives and tinfoil, helix, spark gap, sending key and 6-volt storage battery.

Complete Radio Set of Mr. M'Ilvaine Includes Amplifier.

For receiving I use a pair of 2,000 ohms E. I. Co. 'phones, galena, silicon, perikon and electrolytic detector, small fixed condenser and a two-slide tuner. I ground my set to a well-pump and derive very efficient results.

With a two-wire 300-foot aerial I have many times heard N. Z. G. (Colon). I can easily receive Arlington (N. A. A.) N. A. R. and 9ZS at mid-day. I find the E. I. Co. galena the most sensitive detector I have ever tried when connected up in the proper way. My wireless outfit is situated on a table in a room, but is portable and was out of doors, as the photo shows.



HUBERT M'ILVAINE.

Milroy, Ind.

C. D. PAPPAS AND C. H. RICH'S WIRELESS OUTFIT.

Herewith submitted are three photographs; one of our wireless set and the other of myself and Clinton H. Rich, which I wish to enter in your radio station contest.

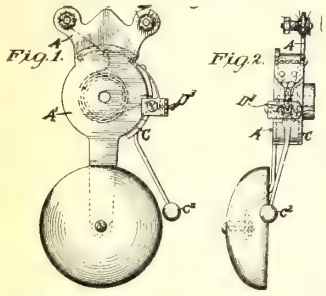
Our receiving set consists of a loose coupler, three home-made plate condensers, one large galena detector, one ten-cent galena detector, two 1,000-ohm receivers, one fixed condenser, three home-made loading coils, etc. Our receiving range is 1,200 to 1,500 miles with an aerial 40 feet high and 60 feet long. It consists of four wires; the spreaders being 8 feet long. We can tune up to 2,000 meters.

Messrs. Pappas (left) and Rich, and Their Portable Wireless Set.

CHRISTOS D. PAPPAS.
CLINTON H. RICH.

Haverhill, Mass.

RADIO CLUBS ATTENTION!

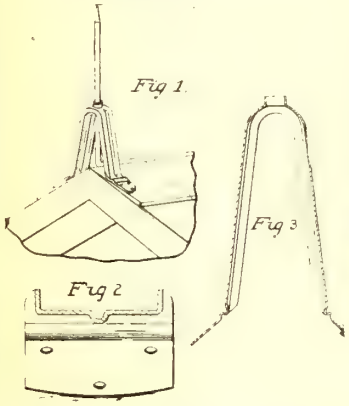


We are always pleased to hear from young Edisons and Radio Clubs. Send a write-up of your Club with photos of members and apparatus to-day to: Editor "Amateur Gossip" Section, The Electrical Experimenter, 233 Fulton St., New York City.

LATEST PATENTS

Electric Alarm Bell.

(No. 1,141,187; issued to Gustav A. Huber.)

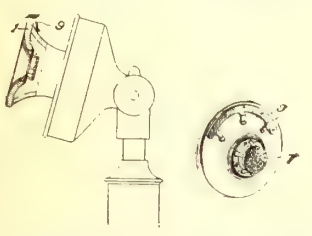


Differing from the usual forms of electric alarm bell construction, this

patentee arranges his bell very simply with a single magnet coil and the iron cheeks A and A^1 of the magnet bobbin attract the vibrating iron armature C, carrying the gong striker C^2. The usual vibrator contact screw D^3 is placed outside of the bell, but the general design is indeed rugged and simplified.

Lightning Rod Points.

(No. 1,140,582; issued to Thomas W. Dodd.)

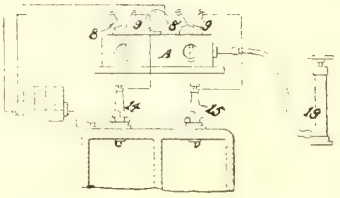


Simplified design for lightning rod points and particularly in rigid bracket supports for same, such as used on pitch-roofed houses. The device is seen in the illustration and the bracket is made from a specially grooved stamping to give maximum strength.

Sanitary Shield for Telephones.

(No. 1,142,600; issued to Russell H. Maxwell.)

A detachable sanitary shield, which may be carried by everyone, is provided for in this patent, and simple means are specified therein

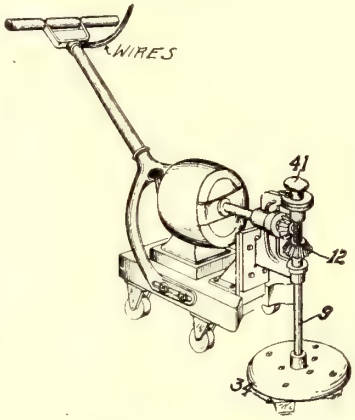


as to methods of quickly attaching and detaching same from telephone transmitters and receivers. Spring clips 9 and 12 enable the user to perform the attachment quickly. The transmitter shield 1 also carries a perforated disc 7, etc.

Auto-Engine Sparking Indicator.

(No. 1,140,816; issued to Claud E. Harlan.)

The inventor of this device intends it for assimilating gasoline engine cylinder conditions in a specially arranged and distinct tank "A." Air pressure, as from a small pump 19, is forced into the chamber "A" and if the spark is all right between the spark plug 8 and 9 terminals under such air compression (which is carried to the same value as that in the engine cylinder), then the ignition system is supposed to be all right. The gauge on top of the chamber measures the air pressure within.

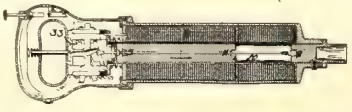


It is difficult to see how this device will show up a short-circuited or befouled spark plug in the cylinder at 14 or 15, particularly as the inventor states specifically that his invention enables engine testers to check up the ignition exactly without removing engine spark plugs 14 or 15.

Electrically-Driven Floor Polisher.

(No. 1,141,287; issued to William B. Thayer.)

A handy form of electric motor-driven floor polisher having several unique adjustable features about it. The polisher 34, having special polishing shoes attached to it, can be raised from the floor and held in that position by a small button 41 and a trip finger on the side of same. The driving pinion 12 is feathered on the vertical shaft 9 of

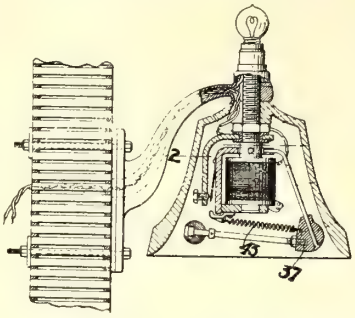


the polisher head to allow of its rising up and down as explained.

Electric Percussion Hammer.

(No. 1,140,447; issued to Achilles de Khotinsky.)

The inventor of this improved electrical percussion hammer for riveting and other work has ingeniously arranged a switching drum 33, controlled by a connecting rod, arranged to be actuated or moved back and forth co-axially by the reciprocating electro-magnetic action of an iron plunger 10. The magnet coils are specially arranged to give the greatest pull on the plunger and also they are made to

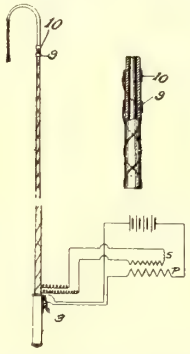


act on the plunger in its return stroke, so that it is magnetically cushioned. A really good invention, it seems.

Electric Signal for Automobiles.

(No. 1,140,492; issued to Harold B. Anderson.)

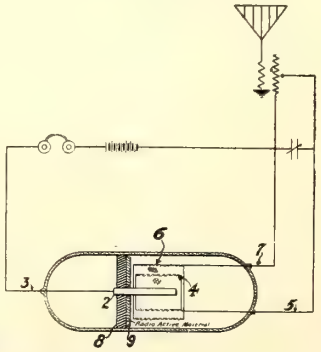
Electrical signaling device for autos, intended to be attached to the radiator of same. Electric signal



lamp is provided as well as special compact form of electro-magnetically operated bell. A single magnet coil attracts an iron armature 2 and this raises the striking hammer 37 in the bell. A spiral spring 43 helps to return the striking hammer.

Electric Whip.

(No. 1,140,365; issued to Henry C. Dixon.)

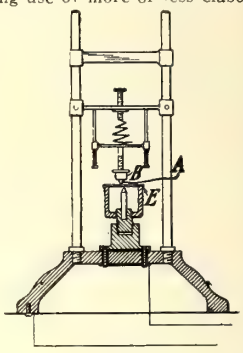


A cleverly arranged whip for

team drivers with two highly insulated electric wires wound spirally along the length of the whip, as shown, and terminating in two metal ferrules "9" and "10." A switch "3" on the handle of the whip controls the primary circuit of a small spark coil. Pressing the button causes a spark to jump from one metallic ferrule in contact with the animal's skin, and so on through the skin to the second metallic ferrule. It is pointed out by the patentee that this arrangement is preferable for team drivers, etc., to that of excessively applying a lash whip which cuts the skin.

Radio Valve Detector.

(No. 1,145,735; issued to Chester Drew Ainsworth.)

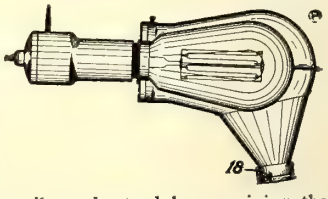


An electronic valve detector for wireless telegraphy, intended to utilize the electron radiations from some radio-active material, such as pitch-blende, etc. As drawing shows, the wireless tuning circuits are hooked up by means of wires, 3, 5, and 7, to three electrodes, 2, 4 and 6. An electron discharge of course is always taking place from the radio-active substances 9, suitably mounted on a disk 8. The incoming etheric waves cause variations in the electronic stream between the electrodes of the valve, similar to the action of the Audion detector. It seems doubtful whether this electron discharge will be strong enough for practical requirements.

New Zinc Compound Radio Detector.

(No. 1,145,658; issued to William E. Ashton and Austen M. Curtis; assignors to J. Odell Fowler.)

An improved wireless detector making use of more or less elaborate

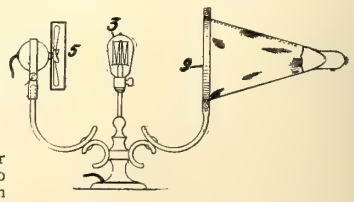


mechanical adjustment frame, as shown, and containing principally as a new feature, a metal cup B, in which is mounted a piece of special zinc compound A, consisting of zinc, oxygen, manganese in the form known as a species of red oxide of zinc. This mineral mass is in contact with a metallic plate or electrode disk E, having half its surface made conductive by facing it with platinum and the other half of it made an insulator by suitable enamel or other means. The detector can thus be cut in or out of circuit by simply turning the disk E.

Electric Egg Tester.

(No. 1,145,466; issued to Frederick W. Dobbel.)

Another form a electric egg tester,



easily understood by examining the drawing. The inventor provides a metallic shell divided hemispherically, so as to be placed over an incandescent lamp by means of a suitable holder, as described. The egg to be inspected, is placed in the opening 18.

Electrical Insect Trap.

(No. 1,144,358; issued to Knut George Gyllstrom.)

As can be seen from the illustration, an electric lamp 3, suitably mounted, serves to attract the insects and they are then blown into a net or catch bag 9, by a strong draught of air propagated by the

electric fan 5. The efficacy of this device is self-evident and several other interesting features are covered in this clever patent.

(Copies of any patent above mentioned supplied at 10 cents each.)

Phoney Patents

Under this heading we will publish hereafter electrical or mechanical ideas which our clever inventors, for reasons best known to themselves, have as yet not patented. We furthermore announce the grand opening of the

PHONEY PATENT OFFIZZ

For the relief of all suffering daffy inventors in this country as well as the entire universe.

We will revolutionize the Patent business immmediately and OFFER YOU THREE DOLLARS ($3.00) FOR THE BEST PATENT. If you take your Phoney Patent to Washington, they charge you $20.00 for the initial fee and then you haven't a smell of the Patent yet. After they have allowed the Patent, you must pay another $20.00 as a final fee. That's $40.00 ! ! WE PAY YOU $3.00 and grant you a Phoney Patent in the bargain, so you save $43.00 ! ! When sending in your Phoney Patent application, be sure that it is as daffy as a lovesick bat. The daffier, the better. Simple sketches and a short description will help our staff of examiners to issue a Phoney Patent on your invention in a jiffy.

PHONEY PATENT OFFIZZ

PHONEY PATENT AFFIRMED, ALOYSIUS DODGASTIT

No. 71177.95 **ROCKAWAY MOTOR** **Patent Applied for 61½ B.C.**

Specifications of Phoney Patent
Hot Application Applied For

To those and whosoever cares:

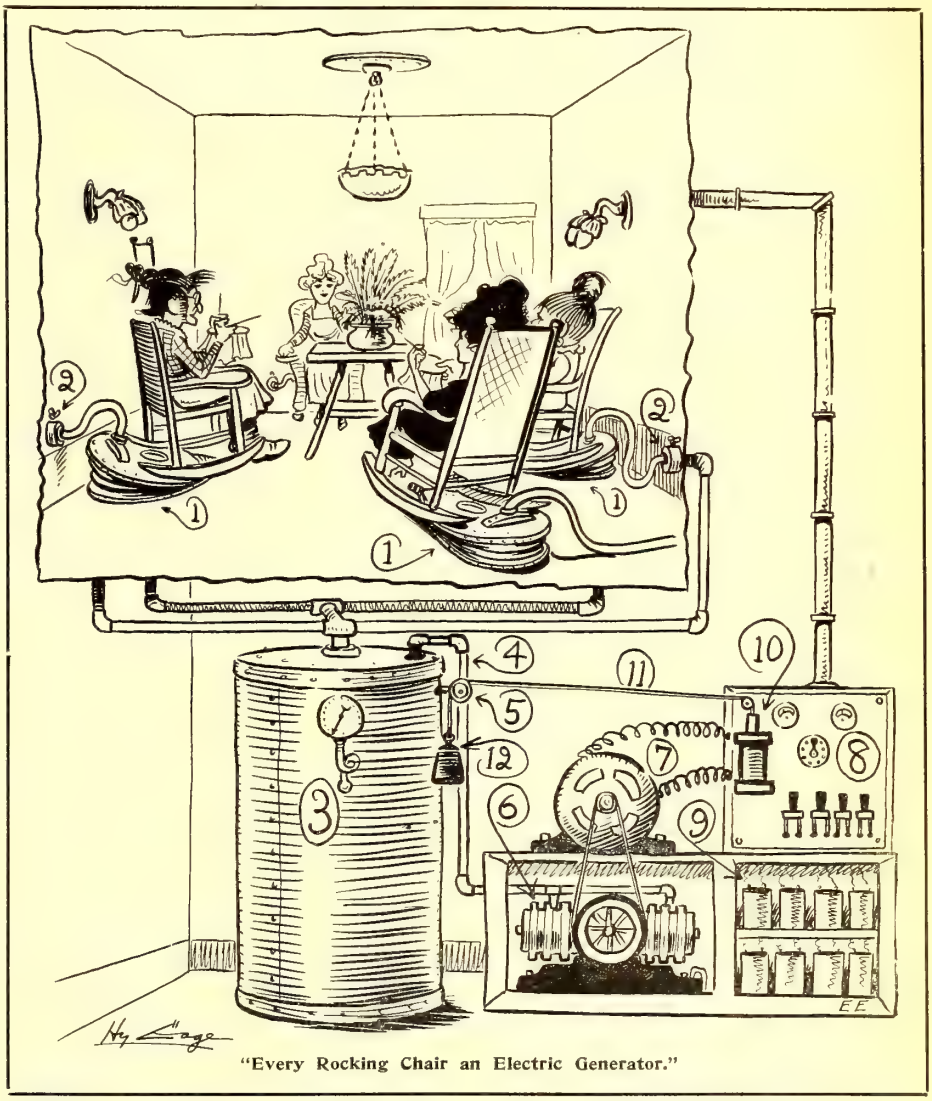
I, Aloysius Dodgastit, of the City of Hades, in State of Exhaustion, have invented an apparatus to absorb, store, use and control in both its primary and its secondary form, electricity, the energy at present wasted by rocking women.

A woman will, by providing suitable means to a rocker, compress 500 cubic feet of air per hour and by actual experiment I have discovered that five times that amount of energy can be obtained from one unit by tying your mother-in-law in a chair and then kissing your neighbor's wife in front of her. (Not the neighbor's front, of course).

My invention consists first of a bellows placed under the rockers of the rocking chairs in the parlor (1). These chairs are connected by means of a flexible, reinforced tissue paper hose to the outlets fastened to the wall (2). Tissue paper is used to prevent the scratching and marring of the furniture. Flexible metal hose, covered with satin, can also be used if desired.

These pipes lead to a large double riveted and welded tank (3) from which the air passes through pipe (4) and valve (5) to a double acting opposed compressed air engine (6). A dynamo (7) is belted to the engine and the energy generated by the dynamo is controlled by switchboard (8) and conducted to storage cells (9). The surplus power of the batteries is used to light up the house, run ice cream freezers, vacuum cleaners, etc. On the switchboard is mounted a solenoid (10) which has its sliding core connected by means of a rope (11) to the valve (5). The action of this is as follows:

If no current is generated by the dynamo, the weight (12) will open the valve, allowing air to flow into the engine, this starts up the dynamo, which gradually shuts off the air, thereby acting as a governor, viz., if the engine runs too fast, the core in the solenoid will be attracted, the valve slightly closed and the engine will drop to its proper speed.



This makes the system automatic and all that is necessary to keep the batteries fully charged is to invite the sewing circle to your home one evening each week and let them rock.

I am patenting this to protect others from making money from the idea, so readers with this patent may go ahead and install one in your own home.

In testimony whereof I have hereunto, for now and for all times, from the beginning of the world till this evening at 9¾ P. M., placed my seal this 20th day of today Anno Domino (sugar) 1991.

ALOYSIUS DODGASTIT,
By his Attorney:
THOMAS W. BENSON,
Philadelphia, Pa.

Witnesses:
O. Pfooee,
G. Wotaboub,
O. Myeye.

"Every Rocking Chair an Electric Generator."

"SOME" SOUNDER.

I wanted to learn telegraphy but had no apparatus; so I invented one.

Here is the description: Take two dessert spoons as per sketch; that's all. Operate as shown. Just try it. It sounds like a real $10 sounder and the speed which you can attain is marvelous. It's all wrong, Baron Münchhausen: it's all wrong!!

Contributed by MULB EGROEG.

[Not having spoons around the office we could not try Mr. "Mulb's" scheme. If

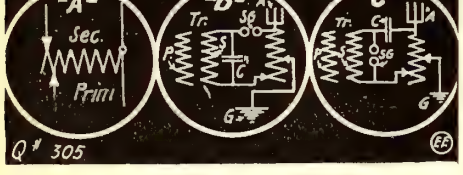
he will send us some of his spoons (solid silver, please), we will try our hand at it. —Editor.]

JAPAN-HONOLULU RADIO.

Wireless communication was successfully inaugurated recently between the new station at Funabashi, near Yokohama, and the Hawaiian Islands. The distance between Funa[illegible] new wireless statio[illegible] Honolulu is

QUESTION BOX

This department is for the sole benefit of the electrical experimenter. Questions will be answered here for the benefit of all, but only matter of sufficient interest will be published. Rules under which questions will be answered:



1. Only three questions can be submitted to be answered.
2. Only one side of sheet to be written on; matter must be typewritten or else written in ink, no penciled matter considered.
3. Sketches, diagrams, etc., must be on separate sheets. Questions addressed to this department cannot be answered by mail.

SOME INTERESTING RADIO QUESTIONS.

(305.) R. N. Turner, Fort Smith, Ark., sends us some uncommon questions below which the editor of this column thinks will be sufficiently interesting to warrant their publication, although usually three questions are the limit. We answer herewith some of your queries:

A. 1. A two-slide tuning coil is superior to a single slide tuning coil in wireless receiving circuits, due to the fact that the coil used in this way operates as an autotransformer, or, in other words, this single coil must do the work of a regular transformer, having two coils; the single winding acting both as primary and secondary. Hence it is evident that if the primary and secondary are to be adjustable independently, as they should be, of course, that it is impossible with a single slide coil to obtain independent adjustment of secondary and primary, but that both secondary and primary circuits, so to speak, must be adjusted in one operation with a single slide. Of course, this gives a very narrow latitude to the adjustment possible. With two slides it is evident that a regular loose coupler action can be approximately duplicated, as the diagram "A" shows.

A. 2. It is an indisputable fact, speaking generally, that a tuning coil or autotransformer is the most efficient type of transformer possible to build. This covers such

Diagrams for Query No. 305.

points as strength of signals received, etc. However, in radio receiving circuits there is often so much static and interference to be eliminated that it has been found that, all things considered, a loose coupled transformer with a distinct primary and secondary winding gives the best all-around results, as the selectivity and tuning effectiveness of such an arrangement is of far greater latitude than that possible with a single coil, the sections of which are all metallically interconnected or in one common circuit.

A. 3. Regarding aerials it seems to be a standard practise, both for commercial and experimental purposes to-day, to make use of a plain straightaway type of antenna. This calls for cross-connected strands at the free end of the aerial flat top and at the lead end of flat top. A lead wire is brought down from each strand and joined to a single, heavy, stranded cable preferably.

A. 4. With regard to the connection of the telephone receivers across the detector or across the fixed "blocking" condenser in the radio receiving hook-up you show this is a matter of minor importance, it seems, from our experience and that of others. Both [illegible] are used practically ind[illegible] for a mathematica[illegible] this matter we refer you to an excellent article which appeared in the February, 1915, issue of this journal, copy of which you can procure from the publishers at the regular price.

A. 5. With reference to connecting the condenser in a wireless transmitting set either across the secondary of a high voltage transformer or in series with the closed oscillatory circuit, as diagrams "B" and "C" show, this seems to make very little difference in most cases and both methods have been used indiscriminately on commercial wireless installations for many years on board ship, etc., by several of the foremost commercial radio companies to our correct knowledge.

The Classified Columns of the ELECTRICAL EXPERIMENTER GET RESULTS

More than 40,000 Electrical Experimenters will see your ad.

A. 6. Relative to the increase in strength of received signals caused by a person touching some metallic part of the aerial or by duplicating this condition by means of connecting a large coil of wire of one lead to the aerial we think that this undoubtedly is due to the increased capacity effect created; and, of course, the greater the capacity of an aerial in micro-farads, the greater its wireless activity.

A. 7. Concerning the long 740-foot aerial composed of one conductor acting better than a multiple wire, four conductor, 185-foot aerial for the wireless receiving of long wave lengths, etc., this is due fundamentally to the fact, as proven in a number of cases on record, that a small aerial when "boosted" by loading coils or condensers, etc., will not act to the utmost efficiency in receiving long wave lengths, which have a value greater than about three or four times the natural period of the antenna in question. Hence you will see that a 740-foot aerial wire will, on this hypothesis, receive 2,500-meter wave length much more efficiently in every way than would be possible with a smaller aerial of the multiple wire type.

This principle has been rigidly followed in all of the latest radio engineering developments, including the design of the large Marconi transatlantic station located at New Brunswick, N. J. These stations use tremendous wave lengths of from 12,000 to 15,000 meters value and the aerials conjointly are also very long, being in the neighborhood of one mile in length, following the principle above mentioned.

A. 8. Regarding the mineral "Cerusite" as near as we know this is similar to crystallized galena, or at least samples which we have tested appear to be nothing else. We have found regular cubic formation galena, as commonly used, to be superior to this so-called "Cerusite." Crystal detectors have been used in receiving transatlantic messages commercially, but nowadays some form of vacuum tube amplifier is most generally made use of.

RADIO QUERIES.

(306.) Harold C. Sever, Pleasant Plains, Ill., asks several wireless questions.

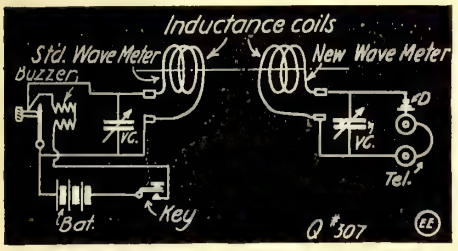
A. 1. The aerial arrangement you show should prove satisfactory indeed for wireless receiving, etc. The metal gutters should not have any appreciable effect on your aerial. By "dead ends" on loose couplers is meant the idle turns of the coils not in use when a certain signal is being received. They, of course, produce a large distributed capacity detrimental to the best operation of the set.

You should try some new peroxide of lead in your detector of that type, as these tablets vary a great deal in their sensitivity.

You are correct in assuming that a carrying capacity of 2,000 amperes per square inch of cross-sectional area for copper is common.

The wave length value of the helix turns in use in the wireless transmitting circuit must be added to the aerial wave length proper.

WAVEMETER CALIBRATION.



(307.) Warren S. Terriberry, New Bedford, Mass., wants to know how to calibrate a new wave meter from a standardized or master instrument of that type.

A. 1. In calibrating one wave meter by means of another wave meter, which is already calibrated, the general method is to make use of an exciting buzzer, shunted across the oscillatory circuit of the standardized wave meter, as the diagram herewith shows.

The wave meter to be calibrated is then placed sufficiently close to the inductance coil of the buzzer excited standard wave meter and several settings or readings of the condensers are noted and a curve can then be plotted through them in the usual way. For instance, the standard wave meter is set at 10 degrees along the scale of same, and if this corresponds to, say,

200 meters wave length then when the loudest signals are heard in the telephones connected to the second wave meter under calibration (which tuning is done by moving the condenser handle over the scale of same) then the point of loudest signals as indicated on the condenser scale corresponds to 200 meters wave length, and this point should be noted.

This process is repeated about every ten degrees around the scale successively, and then all of the points and wave length equivalents are plotted on some square

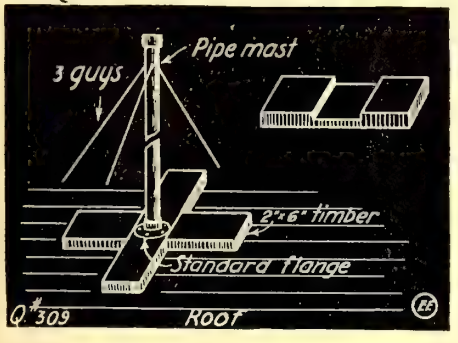
Calibrating a Wavemeter.

ruled cross section paper and a smooth, symmetrical curve may be drawn through the points.

Relative to construction data for undamped wave receiving tikkers would say that a very good idea on same was published in the April, 1915, issue of this journal on page 228, and copy of same can be procured at 5c.

You will find a number of tables given showing increase in wave lengths when one or more wires are added on parallel to an aerial in any of the standard radio handbooks, such as those by Dr. J. A. Fleming.

LIGHTNING SWITCHES.



(308.) D. W. Vallow, Sebring, O., asks for data on lightning switch construction.

A. 1. The copper bar you mention will be all right for lightning switch construction and the moving blade should be 1 inch in width if it is ⅛ inch thick. The blade may be about 5 to 6 inches long and the whole may be mounted on a slate base or preferably on a marble base.

IRON PIPE MAST BASES.

(309.) Patrick J. L———, Boston, Mass., wants an idea on mounting the base of an iron pipe mast on gravel coated roof so as not to damage it.

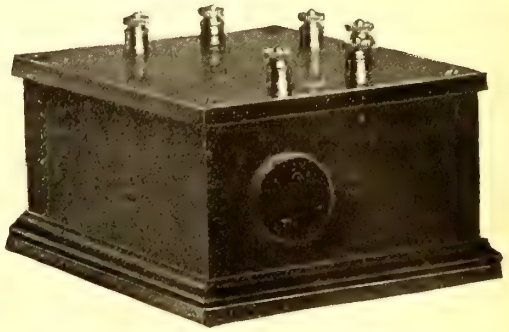
A. 1. We suggest in the sketch a way in which to mount your small iron pipe mast on top of a roof, as you mention, so

Mounting Iron Pipe Aerial Mast on Roof.

as not to damage it. A common way to do this is as indicated in drawing, and the mast here has a substantial foot or base arranged under same, made of some fairly heavy timber, say 2 by 6-inch yellow pine.

If such a mast is properly guyed with about three guy wires, such as stranded galvanized guy cables, it will retain its posi-

Multi-Audi-Fone
The New Wonder in the Wireless World



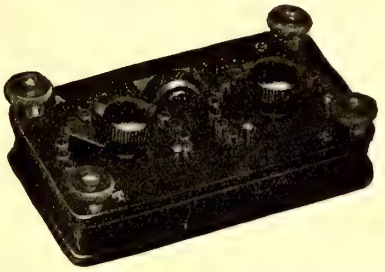
This instrument increases the audibility
ONE THOUSAND FIVE HUNDRED TIMES

Remember that the Multi-Audi-Fone will work equally well with all detectors, including the Audion, and when used with any wireless set will double and even triple the distance, and renders audible hundreds of stations that you can get in no other way, bringing out all nearby stations, as well as those thousands of miles away.

Price, $30.00

SIGNALS CLEARLY HEARD AND ACCURATELY READ WITHOUT HEAD-SETS

The amplification is so great that when two Multi-Audi-Fones are used in tandem and a horn is attached to the receiver, the signals can be heard all over the five story building from our laboratories which are located on the third floor. If the windows are opened, the signals can be heard across the street, even when the trolley is passing.



MULTI-AUDI-FONE

The exact measurements of this instrument are 4¼x3x2½ inches. Weight, 12 ounces

It increases the audibility one thousand five hundred times

MULTUM IN PARVO
(Much in Little)

The exact measurements of this instrument are 3¼x2x⅞ inches.

This instrument is indeed "much in little." It is a marvel of efficiency and campactness, for it combines the CRYSTALOI DETECTOR, which is superior to any other, with a COMPLETE AND PERFECT RECEIVER.

The Crystaloi Detector especially designed for us becomes far more sensitive when used in combination with our Multum in Parvo. This compact little instrument has a wave length ranging from 50 to 3,600 meters, and **will go into your vest pocket.**

Price, $20.00

These instruments in combination have a receiving range of 3,000 miles. They are beautifully finished in triple nickel plate and made of hard rubber composition.

One Hundred of These Outfits Sent On Free Trial

Naturally we must follow the rule of first come, first served. Therefore, if you do not get your outfit at once you will understand that there are others ahead of you and that you will get yours when your turn comes.

Offer to Radio Clubs or Others

We will send, at our own expense, one of these complete outfits to any radio club or any two persons. If you want to try this newest and greatest wireless improvement, sign the following letter. Have it guaranteed by your father or some other responsible man, and we will send the outfit to you on trial.

MULTI-AUDI-FONE: 273 Morris Ave., Elizabeth, N. J., 1915.

Gentlemen:—Please send us, at your expense, one of your complete outfits upon these conditions: First—We agree in no way to mar or injure any of the instruments by taking them apart. Second—We agree to repack carefully any of the instruments we do not buy in the same box in which we received them. The prices of these instruments are understood to be: Multi-Audi-Fone, $30; Multum in Parvo, $20. Head-Set, $5; the outfit, $55. Third—We agree to remit within ten days of receipt of the instruments for such of them as we decide to purchase and to repack the rest as above agreed, and return the same at your expense within ten days after they are received by us.

Very truly yours,

Two Signatures are required
No apparatus will be sent unless responsible person signs this Guarantee

tion all right even in a high wind. Of course, the larger the base timbers are made the more stable the mast will be, and it should in no case be less than 4 to 5 feet in spread.

AERIALS ON SMOKE STACKS.

(310.) Ralph Liddle, Lake Benton, Minn., says he has facilities for erecting a good sized aerial on a steel smoke stack and wants our opinion on it.

A. 1. We might say that there are many wireless plants erected or installed under the conditions you mention, and iron smoke stacks are often used to support aerials very successfully.

It is well in such cases to leave quite a space between the stack and the spreader, say 15 to 20 feet or more, so that smoke or soot from the stack will not coat the spreader and its insulators, thereby providing a bad leak to the ground. It would be very advisable in such cases also to place a metal hood on one end of the insulator, as the sketch herewith shows, to keep the soot

Aerial Fastened to Steel Smokestack.

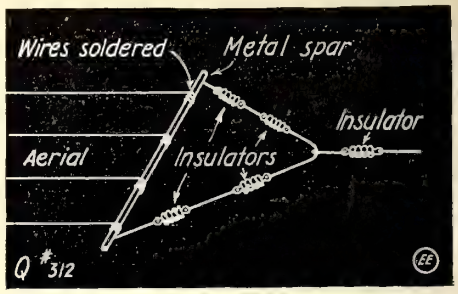
from the stack from falling on the insulator and destroying its high dielectric value.

A DEMAGNETIZING COIL.

(311) James McIntyre, Bridgeport, Conn., inquires for data on making a demagnetizing coil for machine tool work.

A. 1. Unless you have alternating current available you cannot arrange to use a demagnetizing coil in the way you suggest.

It is not practical to make any form of current reverser or commutator for use on 110 volts direct current, which we presume you use on magnetic chuck, of course, and hence you would probably have to use batteries with a small reverser or commutator, rotated by hand, etc., in series with the demagnetizing coil.



If you use 10 or 12 dry cells in series with a commutator or reverser, arranged for hand or motor drive, you could then use a demagnetizing coil consisting of about one pound of No. 18 insulated magnet wire wound into whatever shape you desire the coil to conform for your special requirements.

AERIAL INSULATOR ARRANGEMENT.

(312) Bertram E. Smith, Spring Valley, N. Y., shows two methods in his sketch of placing insulators in aerial spreader ropes, and wishes to know the best of the two schemes,

A. 1. The first method you show in diagram (here reproduced) of arranging four antenna insulators in series in the spreader supporting ropes is practically as good as any, and of course the more insulators you place in series the better the insulation in every way, as the resistance of such an arrangement is naturally higher.

It is quite common to use a metal pipe spreader in such a case, joining the aerial strands to the metal spreader and making sure that a good circuit is produced between it and the strands, etc., by soldering or other means.

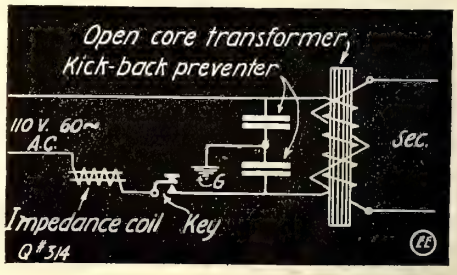
Arrangement of Aerial Insulators.

IRON WIRE CIRCUITS.

(313) J. H. Emrick, Neopolis, O., inquires about iron wire resistance, etc.

A. 1. The 75-ohm Gernsback type relay will operate through circuits having 30 to 40 ohms resistance, and should operate in your case very nicely indeed.

The No. 12 iron wire of common E. B. B. grade has a resistance of 28.46 ohms per mile and "steel" grade wire has a resistance of 30.36 ohms per mile. This data is taken from the wire tables corresponding to the stock carried by the John A. Roebling's Sons' Co.



IMPEDANCE OR REACTANCE COILS.

(314) Thomas Robinson, Chicago, Ill., asks the meaning of "impedance" and "reactance" coils; also their connection in radio transformer circuits.

A. 1. The term "impedance" or "reactance" coil is used indiscriminately, generally speaking, and refers to a coil of wire usually provided with an iron core of laminated form and the coil to be used for controlling the amount of current passed through a circuit or for other purposes, such as choking back the high-frequency oscillations produced by radiophone arc generators, etc.

Diagram, as you request, is given herewith for the connection of open core transformer of wireless type, together with impedance coil in the primary circuit, for controlling the amount of current used.

It also has been found in practical radio

Kick-back Preventer and Open Core Transformer.

installations that such adjustable impedance coils in the primary transformer circuits can be used very efficiently to help tune the radio transmitting set, as regards the total resonance characteristics of the primary and secondary circuits of the transformer.

CONCERNING FILINGS COHERERS.

(315) George L. H—— wishes information on adjusting coherers for wireless sets, as he is having considerable trouble with such a set.

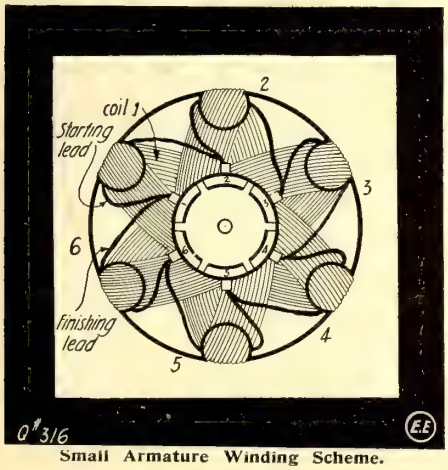
A. 1. Of course, coherer outfits have to be very finely adjusted in any case, and the Marconi coherer sets which were used

some years back were indeed very complicated and fitted with a great number of condensers, choke coils, shunt coils, resistances, etc., in order to make them work as nearly perfect as possible.

However, the Editor of this column has had a great deal of experience with coherer outfits, and can truthfully say that the *Electro* coherer which you have can do very good work indeed, considering its simple make-up. The coarseness and quality of the filings used in the coherer are of great importance, and you can experiment a little along this line to your own advantage, undoubtedly. A good mixture for these filings, and which, by the way, should be quite coarse, is that consisting of 85 per cent. steel grains and 15 per cent. silver. This mixture may be varied until best results are obtained.

The filings should never be touched by the fingers, as the oil of the skin will spoil the sensitivity of the grains. They should always be handled by a small piece of paper bent into a funnel shape or by means of a clean pair of tweezers.

The E. I. Co. 2-inch spark coil has about 50,000 turns of wire in the secondary and 150 turns in the primary. The No. 7,000 *Electro* Tesla transformer has about 30 turns in the primary and 1,000 turns in the secondary.

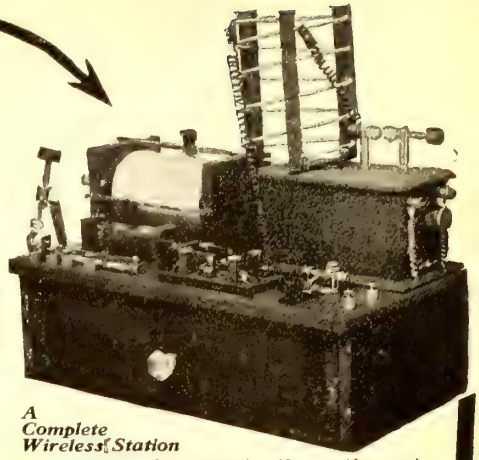


---

(316) Ervin R. Musgrave, French N. M., asks several questions regarding armature winding, storage battery plate design, etc.

A. 1. Diagram is given showing how the winding on the type SS dynamo armature is carried out. Six coils are wound on same, overlapping each other, while the leads from the coils are consecutively joined to the commutator segments as indicated.

In rewinding the armature on your telephone generator about No. 22 insulated magnet wire should be wound on same until it is solid and also quite full. A two-segment commutator must be used if the machine is to give direct current, so as to operate small battery motors, etc.



In regard to the design of the storage batteries and the allowance made in the size of the plates with respect to the ampere-hour capacity, the standard American rule is to allow 50 ampere-hours capacity for every square foot of positive plate surface. It should be borne in mind that invariably the positive plate surface is figured as the length times the height of the plate multiplied by 2, as this plate in most cases is placed between two negative plates, and hence both sides are active in the action of the battery.

Small Armature Winding Scheme.

The standard design of such lead batteries covers the use of practically in all cases one more negative plate than there

OWN YOUR OWN WIRELESS

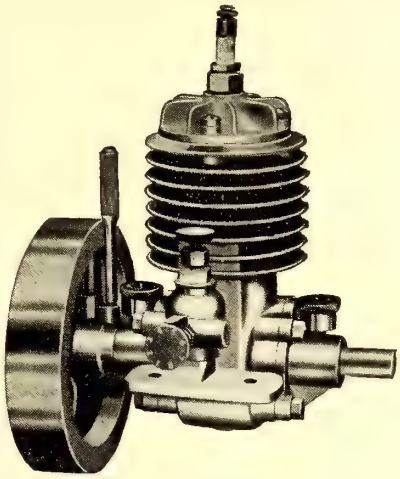
A Complete Wireless Station

Our Universal Cabinet Type B has for its three cardinal features Compactness, Neatness and Efficiency.

COMPACTNESS: All the instruments required for sending and receiving are mounted on a handsome cabinet. There is no necessity for any accessories: the cabinet is a complete wireless station. A drawer is provided in the bottom of the cabinet for spare crystals, pencils and paper and other odds and ends which are used by the operator.

NEATNESS: The Type B set is most handsome in appearance. The cabinet is furnished in solid oak or mahogany, finished with the greatest care. All the brass parts are highly nickel plated and polished. The various parts have been made and finished by skilled labor—there is a commercial touch to the entire set that is lacking in most amateur apparatus.

EFFICIENCY: The various component parts of the receiving and sending apparatus have been selected and designed with a view to making an efficient unit. The tuner is supplied with a winding of either cotton or silk covered wire or bare wire, according to the purchaser's wishes. The potentiometer is absolutely unbreakable and regulates battery current to a fine degree. A potentiometer switch is provided to disconnect the battery when it is not in use, thus saving the battery. Fixed condensers are provided in the receiving set. For sending a ½-inch coil and high capacity helix, as well as a solid brass wireless key of commercial design, are the main features. **The set will receive from stations 1,200 miles away when using 1,000 ohm receivers.**



Price of the Universal Cabinet Type B: With two 80-ohm double pole receivers with 6½ feet of silk covered cord and nickel plated head band . . . $11.95

Price of the Universal Cabinet Type B: With two 1000-ohm double pole receivers with 6½ feet of silk covered cord and nickel plated head band . . . $13.70

Send a two-cent stamp for our interesting catalogue and a special code chart printed on unbreakable fibre. Remember our guarantee: If on receiving our apparatus you find that full value has not been given you, your money will be refunded immediately.

Your Hands Can't Earn the Money You Need

You'll have to work for low wages all your life if you depend upon your hands to make your living. To earn more money you've got to learn how to work with your *head*—you must have *special training* for some particular line of work.

And you can get this training without leaving your home or losing an hour from your work—the International Correspondence Schools can bring it to you right in your *own home* during your *spare time*. They can train you for the very job you want—where you can earn more than enough money to meet your needs.

If you want to advance in your present occupation, the I. C. S. can train you for promotion. If your present work is not pleasant, the I. C. S. can qualify you for a good position in the kind of work you like best.

Every month more than 400 I. C. S. students of all ages and occupations voluntarily report getting better jobs and bigger pay as a direct result of I. C. S. training. What these men did *you* can do.

Mark the Coupon—Now

What occupation attracts you most or what position do you want? Mark it and mail the coupon now, and learn how the I. C. S. can help YOU to earn more money.

are positive plates in the cell to help as much as possible an equal electro-chemical action in the positive plate to prevent its "buckling," which tends to be the case when a negative plate faces but one side of the positive plate, instead of both sides. Also the positive plates are considerably more active electro-chemically than the negative plates, but they do not last as long, generally speaking, tending to disintegrate more quickly than the negatives.

For further data in this direction we refer you to either the Standard Hand-book for Electrical Engineers, price $5, or Storage Battery Engineering, by Mr. Lamar Lynden, worth $3. These books are procurable from our book department.

RADIO TIME SIGNALS FOR THE PUBLIC.

(317) O. A. Duppstadt, Vadergrift, Pa., wants to make the wireless time signals audible to the public outside his store.

A. 1. Some jewelers arrange this matter by having a duplicate set of head 'phones available, which those interested may try on and so listen to the "time signals" coming in, and also some utilize a "bell" outside the store, connected with a Morse tele-

Electric Bell Signal for Radio Time Signals.

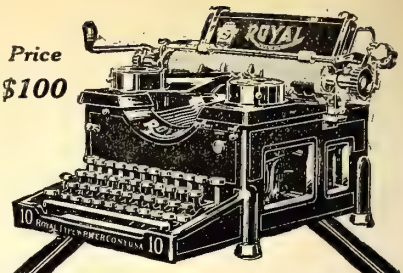
graph key at the radio operating table. As the time signal dots come in on the head 'phones the key is pressed each time, thereby giving bell signals outside of the store for the guidance of the public.

Needless to say, the bell must be arranged with respect to the wireless receiving instruments so that it does not interfere acoustically. This can be accomplished by placing the wireless set in a small booth, such as a telephone booth, if necessary.

STATIC MACHINES IN PARALLEL.

(318) A. J. Boldizer, Gallitzin, Pa., is interested in the parallel operation of static machines.

A. 1. We have never tried running static machines in parallel or in series, but but owing to the practical impossibility of synchronizing the discharges of these machines of the ordinary type, it does not seem practical to attempt such work. With special machines it may be possible.



You will find data given in Nikola Tesla's book, at $1 prepaid, entitled "Experiments with Currents of High Potential and Frequency," on an arrangement whereby static machine discharges can be faithfully duplicated by means of high-frequency transformers and condensers, etc.

Briefly stated, the apparatus is arranged as follows:

G is an ordinarily constructed alternator,

You May Learn Theory, Code and Laws of Radio Communication In Our School or at Your Home,

fitting you for positions paying good salaries with wonderful chance to travel the world over. It's the most interesting profession known and the demand for skilled operators is increasing. Send stamp for catalog which gives full information.

NATIONAL RADIO SCHOOL, 1405 U St. Washington, D. C.

PATENT ADVICE

Edited by H. GERNSBACK

In this Department we will publish such matter as is of interest to inventors and particularly to those who are in doubt as to certain Patent Phases. Questions addressed to "Patent Advice" cannot be answered by mail. Sketches and descriptions must be clear and explicit. Only one side of sheet should be written on.

CAN A. C. TO D. C. MECHANICAL CONVERTER BE PATENTED?

(10) Phil D. Strong, Linwood Farm, Ia., sends in a description of a mechanical device to change alternating current to direct current.

His invention is accomplished by rotating shaft and a commutator, and the correspondent desires to know if it is an original invention and of any practical use.

(A.) Schemes of this sort have been used for quite a while back, and we remember a stage act where the performer converted alternating current to direct current by very similar means, but he used some very large specially arranged commutators for the purpose. The trouble with commutator devices of this kind is that there is too much sparking, and as a rule a much simpler means is provided to-day in chemical or vibrating rectifiers, neither of which spark as much as a commutator device.

While the rotary converters are based on a similar plan to that outlined by our correspondent, there are several phases that enter into their manufacture that make it quite a little different.

We do not think that a patent could be obtained on the device of our correspondent.

ROYALTY ON IMPROVED PATENTS.

(11) James J. Connolly, of New York, writes as follows: "If A invents an article and has it patented, B buys one of these articles and improves on it and has his improvement patented, must B pay A a royalty to manufacture A's article with B's improvement?"

(A.) In regard to the above we offer the following explanation:

It all depends what the invention is. If the improvement of B so changes the article invented by A that he makes a new article of it, then B does not have to pay a royalty to A.

If, on the other hand, the improvement of B is only an addition to the basic invention of A, then in that case B certainly must pay a royalty.

Cases of this kind are usually handled in this manner:

If A has an article on the market and B improves upon it in such a manner that it will make the article more valuable than the original one manufactured by A, it will usually be found that B sells his invention to A; and in an extreme case A allows B to manufacture it, having B pay a royalty on the article.

From the above it will be seen that it all depends on the nature of the invention or improvement, and it is impossible to give further advice without knowing the details.

MORE DETECTOR PATENTS.

(12) W. B., of Uniontown, Conn., wants to know if he could patent a galena detector stand, using two phosphor-bronze wire contacts instead of one.

(A.) We have repeatedly stated that small constructional details in any apparatus do not afford the inventor, even if he could obtain a patent (which is doubtful) any protection. We would discourage all inventors from trying to patent articles which only show small improvements on the article and which do not show distinct material changes. Patents of this class are termed "improvement patents" and as a rule are not worth much, as anyone can easily go around the few claims and substitute another device, which usually works just as well or better.

Even very strong patents which have a great many claims and are quite original are often improved upon or their claims are simply evaded, and it is almost hopeless to patent anything that is not quite original.

We desire to cite a point in case.

About a year ago there was invented by a New York inventor a flashlight in the form of a fountain pen. The patent in this case was the "clip contact" of the flashlight, which "clip" made contact to light the flashlight and at the same time was used to hold the flashlight in one's pocket similar to an ordinary fountain pen. Up to this time of writing some six flashlights are in the market, all having the same feature as stated above, and not one of them really infringing on the original patent. The newer construction simply evaded the original patent by changing the construction slightly, and the original owners are powerless to prosecute, for their original patent does not cover the later designs.

From the above it will be seen that if an inventor has an article which he thinks a really good one, he should try and *cover himself* as thoroughly as possible by submitting to his patent attorney as many variations as are anywhere practical, in order to afford full protection.

REGARDING FOREIGN PATENTS.

(13) Elmer B. Garey, Pittsburgh, Pa., wants to know in what other countries besides the United States a patent should be applied for on an important invention.

(A.) This is really a case for a patent attorney, and without knowing what the invention is it is almost hopeless to give any information. It depends entirely what the article is to be used for and which country it would interest most.

Offhand, we would say that if the patent is important patents should by all means be obtained in the following countries. We also append the cost of patents in the various countries:

Australia	$120.00
Canada	87.50
France	96.00
Germany	113.50
Great Britain	82.00
Japan	120.00
Russia	142.50

Of course there are a great many other countries in which patent protection would quite possibly benefit you, and we advise that you should take up this matter with a competent patent attorney for your own protection.

PATENTING LOUD TALKING TELEPHONES.

(14) Alfred B. Lewis, Chicago, Ill., has invented a loud-talking attachment for the ordinary Bell telephone, the idea being that the ordinary receiver will talk loud enough to be heard in the room. He wants to

VICTOR J. EVANS & CO., Patent Attorneys

NEW YORK OFFICES: 189-191 Broadway **PHILADELPHIA OFFICES: 1429 Chestnut St.**

Main Offices: 779 9th Street, N. W., WASHINGTON, D. C.

GENTLEMEN: Please send me FREE OF CHARGE your FIVE Books as described above.

NAME. . . . . ADDRESS. . . . . .

know if such an invention is practical and whether a patent should be obtained.

(A.) There have been invented quite a few of these devices which usually are merely "acoustic" attachments to the receiver. While in some cases such an attachment may be used, there is really not much practical use for same in the average business office. Most people would certainly not have any use for such a device, as the receiver in its present state of development talks loud enough. Again, most business men would strenuously object to such a device, as they do not wish others to know what is going on over the wire.

While there are of course uses for loud talkers, we would discourage inventions in this line, as they are not of a widely useful nature.

One-Magnet Bells.

(15) E. B. Miller, Newark, N. J., has sent us a model of an electric bell, which, instead of two electro magnets, has only one, but an iron return circuit is provided to obtain a good magnetic efficiency. He wishes to know if a device of this kind is patentable.

A. There have been quite a few of these bells on the market in the past, and while to the best of our knowledge none are manufactured in this country now, there are several German firms who make a very cheap bell and in order to save manufacturing cost provide only one magnet. These bells, however, are not looked upon favorably by the trade, although they are quite cheap. Inasmuch as bells of this kind have been on the market quite a while back, we are quite sure that no patent can be obtained on such a device.

Collapsible Aerial Mast.

(16) H. Forsythe, Elizabeth, N. J., has submitted a drawing of a portable collapsible wireless mast, and wishes to know if the design is practical and whether a patent can be obtained upon it.

A. We have come to the conclusion that the idea is a very good one; we have never to our mind seen anything like it, and from the records obtained in our office, we have concluded that a mast of this kind can be patented. There should be quite a demand for such an article as there is none on the market now, and we would advise you to get in touch with a patent attorney to prosecute your invention. We think it is worth patenting.

What to Invent?

(17) Sylvian McNast, San Diego, Cal., writes us as follows: I have a lot of time on my hands and am very handy with tools, also know a good deal about electricity. I am of an inventive turn of mind and think that if I had a list of articles that are worth while inventing I could perhaps make a success with one of them. Will you be kind enough to publish a list of inventions that are necessary and wanted just now?

A. We have not the space at our disposal to publish a list showing what things to invent as such a list is necessarily very large and at best is incomplete. However, we understand that several of the patent attorneys are printing comprehensive booklets giving lists of articles and objects which await patenting and should net their inventors considerable sums.

We advise you to write to the patent attorneys whom you will find in our advertising columns and we are sure that you will find a lot of food for thought in their literature.

"Financial" Advice.

(18) A. M. S., Peoria, Ill., says he has made an invention which his attorney advises him to patent, but he lacks the funds to obtain a patent and asks our advice what to do in a case of this kind.

A. Cases of this kind are very common indeed, and the only thing to do is to show the invention to some friend or friends in whom you have sufficient confidence and induce them to either loan you the money, or, if this cannot be effected, induce them to share the profits of the invention by selling them an interest in the patent when same is issued by the Patent Office. The latter is, perhaps, the better advice, particularly if you can find someone who thinks well of the invention.

RADIO-AMATEURS JOIN IN RELAY LEAGUE FOR WAR WORK.

Should Uncle Sam ever go to war, he will have to thank a group of young New England amateur radio-experts not only for helping establish the most comprehensive auxiliary wireless system of any country in the world, but also for a rivalry among the thousands of United States amateur workers that could be used to reinforce many times the present wireless network of the country at a minute's notice.

In connection with the formation of the American Radio Relay League by Hiram Percy Maxim of Hartford, ten special amateur licenses have been granted in the New England district, upon recommendation of Henry C. Gawley, the government radio inspector here. Without exception every one of the remaining 700 active amateurs in the district are now seeking to secure the coveted privilege of heading a special relay station such as the special amateur license permits. Thousands of young amateurs in districts all over the United States are seeking the same coveted honor.

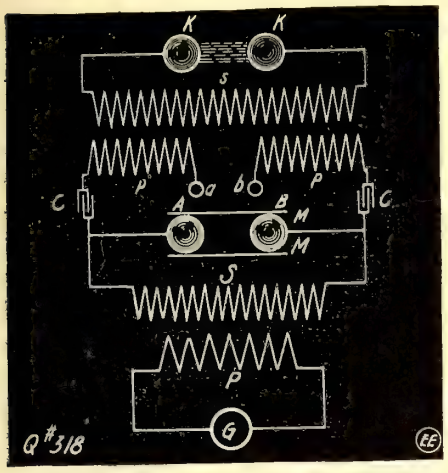
Wireless messages under the special permit can be relayed as far as Chicago and even farther West.

The ten lucky New England men are permitted for relay purposes to use a 425 metre wave length, while the general amateur is restricted to a 200 wave length.

Each special license amateur is closely investigated by Inspector Gawley, reported as possessing an A1 equipment and receives his permit direct from Secretary Redfield of the United States Bureau of Commerce at Washington. He is also designated with a special call letter.

His appointment is specially significant since Uncle Sam grants a special license only after having made sure that the recipient will materially benefit his wireless service.

Mr. Gawley, in discussing the new relay chain, said:



"The League will be of immense help in case of war. It adds to my duties, but on the other hand it brings me into much closer touch with the special amateurs and helps to perfect the government's control over all the wireless amateurs in the league.

"The permits are granted only from year to year. The special license assures us of an active station. If it is not active a license renewal will not be granted. In this way the entire wireless field is carefully guarded. The league members can relay messages from Coast to Coast, and, in fact, to all parts of the country, the maximum distance being about 400 miles.

QUESTION DEPARTMENT.

(*Continued from page 230.*)

supplying the primary P of an induction coil, the secondary S of which charges the condensers or jars C C. The terminals of the secondary are connected to the inside coatings of the jars, the outer coatings being connected to the ends of the primary

Imitating a Static Machine Spark with High Frequency Coils.

p p of a second induction coil. This primary p p has a small air gap a b.

The secondary s of this coil is provided with knobs or spheres K K of the proper size and set at a distance suitable for the experiment.

A long arc is established between the terminals A B of the first induction coil. M M are the mica plates.

Each time the arc is broken between A and B the jars are quickly charged and discharged through the primary p p, producing a snapping spark between the knobs K K. Upon the arc forming between A and B the potentials fall, and the jars cannot be charged to such high potential as to break through the air gap a b until the arc is again broken by the draught.

In this manner sudden impulses, at long intervals, are produced in the primary p p, which in the secondary s give a corresponding number of impulses of great intensity. If the secondary knobs or spheres K K are of the proper size the sparks show much resemblance to those of a Holtz static machine.

A. 2. A sinusoidal current is merely an alternating current which changes from positive to negative many times a second, and having a symmetrical wave form.

TELEGRAPHONE QUERY.

(319) J. W. Arnold, Little Rock, Ark., asks how many times the steel wire in the telegraphone may be used to record messages on, or if it can only be used once.

A. 1. The arrangement you speak of will probably work out very well for use in conjunction with the telegraphone. The steel wire used in the telegraphone is, of course, used over and over again, and the "talk" registered on same magnetically is obliterated or removed by simply reversing the wire through the machine and bringing in close proximity to the moving wire a steel horseshoe magnet, which demagnetizes the wire so far as the message on it is concerned. In the commercial machines an electro-magnet is generally used for the purpose.

HIGH VOLTAGE RECTIFIERS.

(320) W. C. Ewing, Fayetteville, N. C., wants to know if an electrolytic rectifier such as the E. I. Co. build, can be used

(*Continued on page 234.*)

DOCTOR GIVES AID VIA WIRELESS.

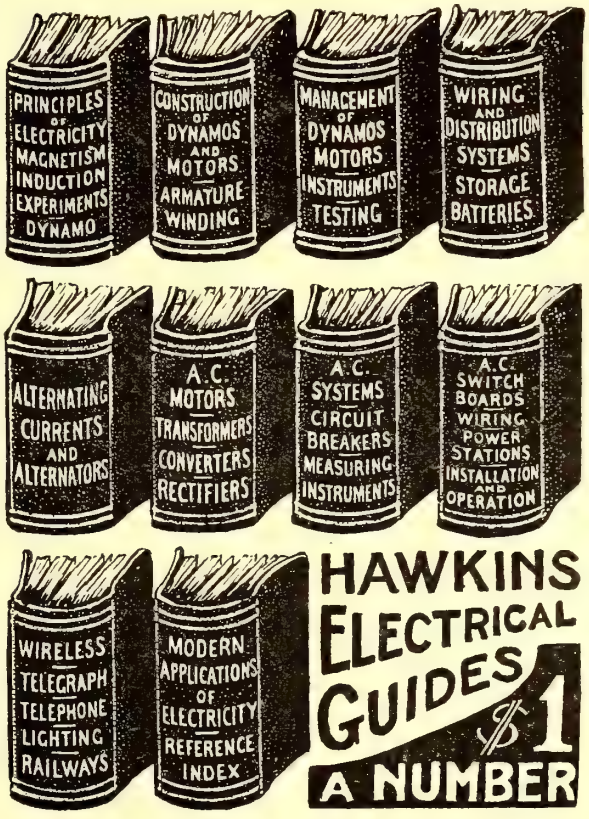
The wireless invention has again proven its value. Capt. Lane, of the steamship "Bradford," arrived at Philadelphia from Tuxpan, Mexico, and tells a story that on the second day out a sailor was taken ill. No physician being on board the wireless operator swept the sea with his wireless in search of one. A British warship answered, but refused to give her location, and said she could not leave her post. The man's symptoms were wirelessed to the ship's doctor, who diagnosed the case as pneumonia. The physician then wirelessed a prescription to Capt. Lane.

AIRMEN ADD TWO TO NAVY BOARD OF INVENTORS.

The nomination by the Aeronautical Society, at the request of Secretary Daniels, of Hudson Maxim and Matthew B. Sellars for members of the Naval Advisory Board on Invention brings the membership of the board up to seven, the other members being Thomas A. Edison, Alexander Graham Bell, Orville Wright, Henry Ford and Charles P. Steinmetz.

The Aeronautical Society is the first of the various engineering and scientific societies to respond to Secretary Daniels's request that they nominate from their membership for places on the board.

This Splendid



LIBRARY of ELECTRICTIY

Sent Free for Examination

$1 Per Volume—Pocket Size—Leather Bound

HERE is a set of books that no man in the ELECTRICAL FIELD should do without. This is the ELECTRICAL AGE in which we live; ELECTRICITY now controls more trades, directs more men, offers more opportunities than any other power that man has yet discovered. Do you wish to know the underlying principles of **Modern Electrical Practice?**

If so, **HAWKINS ELECTRICAL GUIDES** will give you the information. In reality they are a school within themselves, containing a complete study course with QUESTIONS, ANSWERS AND ILLUSTRATIONS, written in plain everyday language so that a practical man can understand.

The How, When and Why of Electricity

Read over the titles shown on the back of each volume, and note the scope of each book. They are handsomely bound in flexible black leather with gold edges and will readily go in the pocket. **They are not only the best, but the cheapest works published on Electricity.**

FILL OUT the Coupon now and get this practical education in electricity "Written so you can understand it."

"That's Just What I Need"

Each book is complete in itself, eight numbers now ready, and will be supplied $1.00 per number, but we believe that the complete set is the best bargain. The books can speak for themselves and a careful examination, page by page, and illustration by illustration, will convince you of their big value. If you will fill out the following coupon giving all the information requested, *we will submit the first eight volumes for examination on conditions named.*

Theo. Audel Co., 72 5th Ave., New York—Free Examination Offer

Please submit me for examination HAWKINS ELECTRICAL GUIDES. (Price $1 each.)

Ship at once prepaid the first eight numbers; if satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

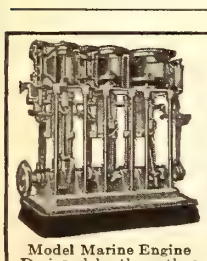
17 FREE SCHOLARSHIPS

ARE NOW BEING OFFERED



LEARN TELEGRAPHY and WIRELESS FREE

The confused condition of the commercial world has created a vast increase in the use of wire and radio. We believe that students who start now will reap the advantages of great opportunity created by the war.

This contest requires no study or special knowledge; anyone with mind enough to learn telegraphy competes on an even basis. Send us 25c (now) for necessary contest sheets, entry blanks, etc., and our book on "Telegraphy and Wireless as an Occupation." You'll enjoy the entertainment this novel contest affords.

Consulting Engineer, 10 Meigs Bldg., Bridgeport, Conn.

for rectifying high-voltage alternating current, such as 90,000 volts.

A. 1. We believe that special apparatus working on the vacuum tube principle probably can be furnished by the General Electric Co., Schenectady, N. Y., to produce high-voltage direct current in the form of a static charge for the purpose you have in mind. Its Kenotron rectifier tubes, for high alternating-current voltages, should be all right for your work.

WILL INDUCTION COILS OPERATE ARC LAMPS?

(321) A. L. W———, Isle of Pines, W. I., speaks of using an induction coil for operating arc lamps.

A. 1. Induction coils cannot be used to operate arc lamps or other such apparatus, owing to the high voltage of the current and to the low amperage of same, and to the fact that this secondary current is an unsymmetrical one of irregular frequency with many long "dead" time periods. Induction coils may be made with any voltage ratio existing between primary and secondary windings desired.

The voltage ratio is primarily dependent upon the number of turns in the secondary coil compared to those in the primary coil. For instance, a secondary coil composed of 500 turns would give an increase of twice the primary voltage if the primary winding comprised 250 turns of wire, and vice versa.

UNBALANCED 3-PHASE A. C. SYSTEM AND WIRELESS RECEIVING.

(322) Barney Lawson, Houston, Tex., inquires about an "attic" indoor type aerial he has erected, and wonders if it would pass the Fire Underwriters' inspection.

A. 1. The aerial you mention would most probably be all right from the electrical and Fire Underwriters' point. We would strongly suggest, though, that with such indoor aerials lightning rods be placed on the exterior of the roof of the house.

If you employ an "L" shaped aerial it is best to connect the lead-in to one end of same.

We do not believe that any unbalancing of the three-phase system you speak of would materially affect the wireless receiving apparatus, so far as can be judged without knowing exact details as to the relative position and location of all of the apparatus, its wiring and nearby alternating-current circuits, etc.

TRANSFORMER DATA BOOKS.

(323) Dr. C. C. W———, Buffalo, N. Y., desires transformer construction data and books bearing on the subject.

A. 1. The data you desire, generally speaking, is given in Mr. Curtis' excellent 25-cent book entitled "Construction of Induction Coils and Transformers."

Another excellent work which will be of great service to you in this direction and containing data for all sizes of wireless transformers up to 5 kw., given in considerable detail with tables, etc., is the work known as "Wireless Telegraphy and High Frequency Currents," by Prof. La V. Twining. Our book department can furnish this book at $1.50 prepaid; also the book by Mr. Curtis.

The method of calculating the secondary and primary windings is thoroughly explained in this book by Professor Twining, as well as a host of other problems in this direction.

RADIO SIGNALS NOT CONSTANT.

(324) A. B. Rowland, Stuttgart, Ark., complains that incoming wireless signals at his station have for a year or more tended to start off strong and then faded away. He has been unable to locate any faulty circuits.

A. 1. The conditions you mention in your wireless station are common, and in most cases that we have investigated of this nature it has usually been found that the trouble is due to a loose or faulty connection at some point.

In one case it was found to be due to a swinging loose joint in an aerial lead-in wire. Sometimes this swinging joint, which was not a perfect one, would open the circuit, so far as the reception of wireless signals was concerned.

We have looked over your query carefully and would suggest in closing that you very carefully examine every piece of apparatus in your set, and especially the binding posts, etc., to see that they are firmly tightened up. Changing sensitivity in the detector is sometimes the cause of this trouble (check this by throw-over switch and two detectors), and a swinging aerial can cause this phenomenon. Atmospheric electric charge variations possibly have some effect.

REGARDING DR. COHEN'S NEW NAVY RECEIVING SET.

(325) Spencer Hass, Kankakee, Ill., asks several questions about Dr. Cohen's new navy type radio receiving set.

A. 1. Relative to the article published in *The Electrical Experimenter* for July,

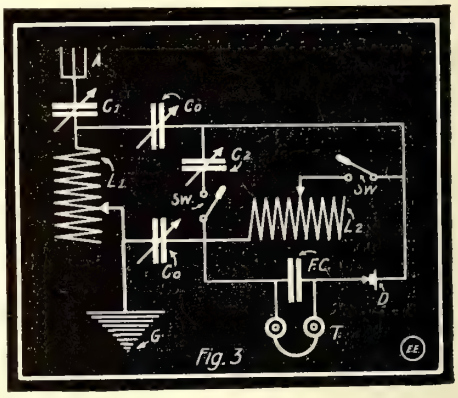

Diagram of Dr. Cohen's Improved Navy Type Receiving Set.

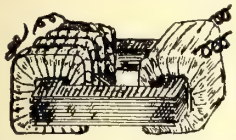
1915, on "Dr. Cohen's New Navy Type Wireless Receiving Set": The inductances L^1 and L^2 are in the form of tuning coils, as you suggest. These may be of different sizes, depending upon the wave length values required for the circuits. Several of our readers have communicated with us, stating that they have found this system very fine indeed, and much superior to anything they had ever tried heretofore.

The purpose of the two switches in the tuning circuits is to enable the inductance L^2 or the variable condenser C^2 to be cut out when tuning this set to different wave lengths. When inductance L^2 is cut out of circuit the path of the oscillations is through inductance L^1, around the circuit through condenser, say C O, to the detector D, thence thru fixed condenser F C and on through the second variable condenser C O back to inductance L^1.



When inductance L^2 is in use in the circuit, then the oscillations are tuned through L^1, two variable condensers C O, and C O and inductance L^2.

The set works similar to an ordinary wave meter, and the detector and fixed condenser F C, with 'phones across it at T, simply act to detect when maximum resonance takes place in the closed oscillatory circuit just mentioned.

The vertical and horizontal wires just below the condenser C^2 are joined as you

Here It Is At Last!

This 1/6 K. W. Closed Core Transformer **$6.85**

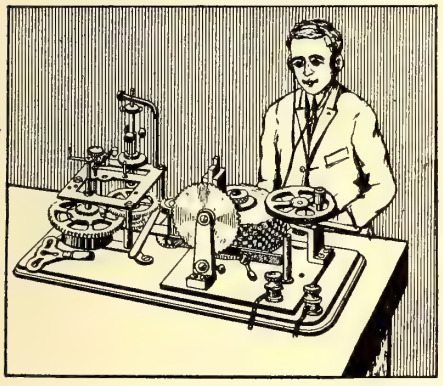
After months of experimenting, and after making dozens of designs and models we have finally produced a thoroughly practical *closed core wireless transformer* to retail at $6.85, the price that formerly you had to pay for spark coil and batteries.

We have sacrificed nothing in quality or manufacture. The size is smaller—that's all.

This transformer will send messages *twenty* (20) *miles*, with a good aerial, instead of the 2 and 3 miles obtainable on spark coils. Best silicon iron is used in its construction; the best enamel and cotton covered wire; mica insulation; sectionally built.

It will throw a heavy, crackling spark that with proper condensers will fill a gap with a ball of fire almost 1-4 in. in diameter.

This heavy spark will send six (6) times as far as 1 in. spark coil.



Send money order today for this new, marvelous little transformer. Shipping weight 10 lbs.

Big Catalog of Newest Experimental Goods, 4 cents in stamps.

Write today for our different kind of catalog. New things in wireless and electrical goods. New prices.

THE MARVELOUS RADIOCEPTOR

Time receiving cabinet set. A guaranteed interference preventer. Mounted in beautiful bog oak cabinet. Comprises loading coil, tuning inductance, two interference preventers, detector, condenser, making it the most efficient radio set on the market to-day. Tunes from 200 to 3000 meters. Size 18¼x6x5¾. **PRICE, $15.00.** Send 2c. stamp for booklet to-day.

IRVING RADIO LABORATORY
30 Irving Place Brooklyn, N. Y.

TYPEWRITER PRICES SMASHED

Yes sir. I have smashed typewriter prices right and left, and I guarantee to sell you a machine for less money than anyone else. I am the largest rebuilt typewriter buyer in the United States.

500 MACHINES AT $10 TO $15

Do not pay 20 to 40 per cent more when you can buy from me. Rebuilt typewriter prices have advanced tremendously, but I still stick to the same prices.

All Machines Guaranteed For 3 Years

When you buy from me, you get a guarantee to keep the machine in repair for 3 years. Write for **FREE** descriptive circular.

"Spot Cash" Guarantee, Pres.

Dearborn Typewriter Exch., Dept. 1 Chicago

mention. The variable condensers may have a capacity of any ordinary value, and of course this depends upon the wave length to which the set is tuned. An ordinary value for same would be .001 M. F., and larger condensers may be used, giving greater wave-length capacity.

CHANGING SERIES DYNAMO TO SHUNT.

(326) J. D. Dalney, Dallas, Tex., has a small dynamo which he wishes to convert from series to shunt-wound type, i. e., with the field winding hooked across the armature brushes.

A. 1. You will undoubtedly have to rewind the field of your machine of the series type if you desire to convert it into a shunt-wound machine.

Generally speaking, the field coils should be rewound with magnet wire about 4 to 5 sizes smaller in circular mils area than the wire at present in use for the series field. About the same amount of wire should be used as regards weight, or also a proportionately greater amount of turns should be placed in the coils.

ELECTROLYTE DENSITY FOR INTERRUPTERS.

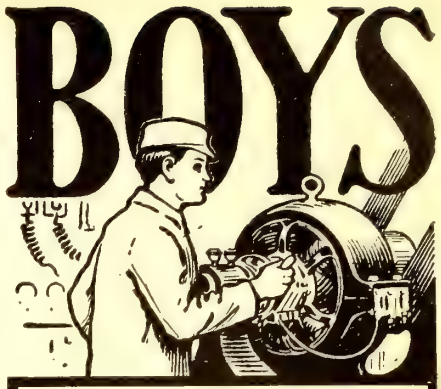
(327) H. Bennett, Clarinda, Ia., wants to know the specific gravity of electrolytic interrupter solution.

A. 1. In regard to the solution used in the Gernsback electrolytic interrupter, would say that sulphuric acid only has to be added every couple of months or so.

The specific gravity, if measured by a hydrometer, should register about 1,210 degrees.

The solution in the interrupter is kept up to its proper level by the addition of pure water from time to time as necessitated by the evaporation of the water in the solution.

A NEW DRY CELL SEARCHLIGHT.



There are numerous uses for a vehicle searchlight that may be operated successfully from dry cell batteries. The new Pittsburgh searchlight, illustrated herewith, employs a powerful focusing lens in connection with an 8-inch parabolic reflector, which produces a beam of light with ample power for automobile and motor boat use. The current consumption is only one ampere (thus making the ordinary dry cell battery an economical source of current supply). The bulb is a 6-volt Mazda, and the lamp can therefore be used with any 6-volt lighting system, or with ordinary dry cells. For automobile use it may be mounted on the door or wind shield. It not only serves as a searchlight for reading signboards, turning and backing, but answers the purpose also of an auxiliary headlight for use in emergency cases. It gives the gaslighted car the use of an electric light whenever needed.

New Auto Lamp—Works on Dry Cells.

NOTICE!!!

Big Money in Electricity

The electrical industries offer wonderful opportunities for boys with a liking for electricity. The salaries paid to trained men are large—promotion comes rapidly, and, best of all, the profession is not overcrowded.

The opening of new lines, from time to time, (such as wireless telegraphy and telephony), promise attractive and paying fields to those who wish to specialize. The *will to do* and *Special Training* will bring success to you.

The International Correspondence Schools of Scranton can help to make you an expert in electrical work. Hundreds of boys have already won success through I. C. S. help. You can do the same. Everything is made so clear that you can learn in your spare time, regardless of where you live or what you do. No books to buy.

There's big money in electricity. Get after it by marking and mailing the attached coupon today. Finding out costs you nothing.

SEND FOR COPY OF OUR

New Wireless Manual No. 9

Its pages contain simple formulas for calculating the natural period of an antenna; capacity of a receiving or transmitting condenser; spark frequency of rotary spark gaps; tables for calculating the correct amount of wire for the construction of magnets and tuning coils; tables for ascertaining the spark lengths of different voltages; the Federal regulations regarding the restrictions of wave lengths for amateur stations; instructions for the installation, maintenance and operation of wireless stations; directions for learning the code, workable diagrams and a complete list of up-to-date wireless instruments and accessories, together with other features of interest to the amateur or professional wireless enthusiast.

Containing as it does a fund of valuable information not generally contained in a catalog it approaches nearer a text book in the fascinating field of wireless telegraphy.

It is printed on good stock with a heavy paper cover in two colors. No expense has been spared to make it accurate and reliable.

We make a charge of 10 cents for it which amount will be allowed on an order amounting to $1.00 or more.

Send for our Pocket Catalog W 28

It contains over 240 pages, with over 1,000 illustrations, describing in plain, clear language all about Bells, Push Buttons, Batteries, Telephone and Telegraph Material, Electric Toys, Burglar and Fire Alarm Contrivances, Electric Call Bells, Electric Alarm Clocks, Electrical Batteries, Motor Boat Horns, Electrically Heated Apparatus, Battery Connectors, Switches, Battery Gauges, Wireless Telegraph Instruments, Ignition Supplies, Etc.

THE WONDERS OF RADIUM.

(*Continued from page* 183.)

Upon focusing the lenses and upon looking through them, one will see that the screen is continually giving forth small sparks, which as the Radium salt is brought closer to the screen, increases the brilliancy and frequency. A beautiful scintillating effect is obtained, impossible to describe. In our Fig. 10 we see a magnified view of the lighting up of the screen on the inside of the Spinthariscope, one-half of the screen having been covered up.

Our Fig. 11 shows a very enlarged view of the inside of the Spinthariscope, but it does not adequately show the beautiful color effects obtained with this instrument. It goes, of course, without saying that there is nothing to wear out in this instrument and it will last as long as the speck of Radium will last, i. e., 2,500 years and longer. It was with this instrument that Crookes demonstrated that the emanation of Radium consisted of millions of positively charged atoms hurled off from the Radium salt with terrific velocity, and it is this which causes the particles of the zinc sulphide to sparkle and glow.

We have stated elsewhere that Radium is capable of giving off a tremendous amount of heat. Indeed, this shows us a way where future man will smile when he reflects how we used coal to-day, which gives but 5 per cent. of its actual energy when translated into steam, the rest being carried off as waste heat. The future man will, no doubt, laugh at the idea of how we had been using **6,000 tons of coal** for a single trip (costing some $12,000, valuing coal at $2 per ton, which is very cheap), to propel a modern steamship like the "Mauretania" across the ocean, with the accompanying vast amount of space required in which to store these 6,000 tons of coal. Not only this, but he also will undoubtedly smile when he contemplates the very cumbersome machinery necessary in order to transform the latent energy in the coal into steam, when his amazement will be even greater.

It has been found that when burning one gram of coal that only about 8,000 calories of heat are obtained. In this change, however, 2⅔ grams of oxygen are consumed, so that per gram of the two compound substances we only get 2,200 calories of actual heat. This combustion is instantaneous. It must be renewed all the time, as coal will, of course, burn up very fast. If we now substitute Radium for coal we find that one gram of Radium develops 133 calories of heat per hour. There are 8,760 hours in the year; therefore, figuring on this basis, a gram of Radium will net us about 1,160,000 calories during the course of the year. In one year 1/2500 part of the Radium changes. Thus, during the complete change of one gram of Radium no less than 2,900,000,000 calories would be evolved in 2,500 years.

Considering this basis of energy transformation, the power latent in Radium is well over a million times greater than that furnished by the combustion of coal. This gives us a good idea of the tremendous power of the mysterious element—Radium.

To continue, with regard to driving a modern ocean greyhound across the sea by means of Radium instead of coal, the illustration at Fig. 12 will be of interest. This shows fairly well the small amount of space consumed by the Radium boiler which would undoubtedly be used on board the steamship.

Getting down to actual figures, we have seen that 6,000 tons of coal used for such steamships as the "Mauretania" would cost, let us say, on the average $12,000. It has been calculated that to give forth the same equivalent of energy for one trip of the steamship would necessitate the employment of .15 (fifteen-hundredths) of a gram of this precious substance, which is worth $96,000 per gram, according to the market figures which have prevailed previously. Thus the .15 gram of Radium (and considering that all of the energy in this fraction of a gram of Radium could be liberated during the five days' run of the steamship) would cost .15 of $96,000, or $14,400 This is a little higher than the cost of the coal, but it should not be forgotten for one moment that this Radium here proposed for propelling the steamship would only weigh the fraction of a gram, and there being 28.35 grams to the ounce, avoirdupois. Also the 6,000 tons of coal here involved would weigh 5,448,000,000 grams; or in other words, the coal necessary to be carried on board the steamship for a single trip would weigh approximately 35 billion times more than the total weight of Radium necessary. Again, and considering the new Government rate* just made effective for the reduced cost of Radium, which is one-third the old market price, the actual cost of the .15 gram of Radium would be $4,800. This does not even begin to mention the valuable space taken up by the ponderous machinery, boilers, bunkers for the coal etc., which with the Radium would, of course, fall away entirely. The only machinery necessary would be a small boiler with water, a turbine engine and the speck of Radium. Our arrangement as shown at Fig. 13 could, of course, be used with modifications.

It consists of a boiler of spherical form having a radius of several feet and a small shell of iron, with the Radium hung in the center of the boiler, as shown. Such a boiler would, of course, take up but a very small space, and is readily installed. The energy supplied by the Radium is distributed equally in all directions, and therefore the heating of the water in every part of the boiler is practically equal.

Submarines could be easily propelled with this wonderful substance, which naturally would replace cumbersome oil engines, thereby preventing accidents from explosions and also the danger from fumes given off by storage batteries during the period when the vessel is submerged.

An interesting illustration of the marvelous power or rather of the inherent energy in Radium is shown in our Fig. 14. It seems incredible that such a ponderous structure as *the Woolworth building, weighing* 103,000 *tons, could be lifted by means of the energy evolved from* 1/50 *gram of Radium.* Nevertheless this is a fact. It has been shown that .0225 gram of Radium, costing $2,160, if caused to act through its normal life of 2,500 years continuously on a powerful electro-magnet, would furnish enough energy to lift the Woolworth building one foot above the ground, as shown in our illustration. Of course the illustration which we offer is only made to convey the idea graphically and is not in reality complete, for it would be necessary to first transform and store the electrical energy of Radium into a charging plant, such as a monster storage battery, charging this storage battery for a period of 2,500 years without interruption. At the end of this period we would have (theoretically) accumulated enough energy to actuate the immense magnet and for a few moments there would be enough energy at hand in our storage battery to lift the Woolworth building clear. In other words, we would

*As we go to press the Government announces that it has succeeded in producing Radium at a cost of $36,050 a gram, which is exactly one-third of the cost it was heretofore. This Radium is now produced from our Cornotite mines in California and Colorado.

ACCEPT THIS BOOK FREE

IT'S INVALUABLE YET CAN'T BE BOUGHT

Just as you will receive it, cloth bound, size 7 x 10¼ ins., 160 pages, 20 lessons, 350 illus., 30 tables, with every bit of information on Wireless you can possibly want, besides valuable information on Electricity, Magnetism and Theory of them **—and it's FREE as explained.**

Will you take a 20 lesson Wireless Course absolutely FREE—even postage charge prepaid ?

A course that tells you everything you can possibly want to know about "Wireless" starting off in Lesson No. 1 by explaining the Principles of Electricity. The Second and Third Lessons are devoted to magnetism. motors; generators and wiring. And then, by simple easy stages this wonderful Course takes you into "Wireless." The mysteries of "Wireless" are unfolded to you by the use of such simple language so skillfully used, that of necessity you must understand every word. The subject is not treated superficially, however, for there is a whole lesson devoted to the Theory and Mathematics of this epoch marking subject. To lend charm to the Course, the last Lesson (No. 20) is devoted to a history of Wireless and the men who developed it. The wireless course positively cannot be bought, but will be sent absolutely free with a full year's subscription (12 numbers) of the Electrical Experimenter at $1.00. It's the biggest dollar's worth you can ever buy anywhere at any time. Send for it to-day enclosing $1.00. Send **now** before you forget.

The coupon below is a convenient way. **But do it now.**

*Canada and Foreign Countries, $1.25—2 years, $2.50.

have obtained enough power for a few moments to lift 103,000 tons one foot above the earth! And 1/50 gram of Radium accomplished it!

While the above example clearly demonstrates the tremendous inherent power that lies dormant in Radium, there are, of course, thousands of other applications which could be successfully worked for the benefit of man.

Verily, we have no conception of the marvels that lie buried in the future!

WIRELESS AND THE CLERGY.

A wireless dispatch of 80 words is being sent by the Canadian Government to the clergy on the Magdalen Islands in the Gulf of St. Lawrence, to be read from the pulpits each Sunday morning in order that the inhabitants, who are shut off from the outside world, may know of the progress of the war.

OMEGON.

(*Continued from page* 190.)

"It took two men to carry out wan of thim sleepin' kids, an' after a couple of trips they'd go to sleep thimselves. The ship's engines stopped an' th' second engineer—th' last man awake in th' engine room—a brown, wild-eyed little divil, crawled out an' hugged a stanchion close to me. Thin he slid down like a strip of liver an' closed his eyes.

"Thin th' Japs lowered their flag, an' soon after—hivin bless yez, Cawthorne,—th' flags of three other ships came down."

Ned stepped close, grasped the captain by both shoulders, and demanded: "The other boats, Mulray! Did you see anything of them?"

"Divil a——" But he was interrupted by the surgeon.

"A message has just come in from Gualala, Mr. Cawthorne. Your five submarines are there, and all well. They've put the enemy's flagship and four others out of commission and you haven't lost a man. I don't know what those boats cost you, but——"

Ned interrupted with a grin: "They cost, covering everything, less than three hundred thousand. That's outside of the *Sarah Q*. She's good value yet, and I've got some new work to put her at."

"Three hundred thousand!" gasped the surgeon. "And those five superdreadnaughts didn't cost less than fifty millions before they left the yards!"

That evening Cawthorne and the men who had operated the submarines with him supped together hilariously in the cabin of the *Sarah Q*. She was steaming back to San Francisco, the little boats in tow. As they lit cigars and pipes, Ned slipped a handful of checks into Kilroth's hand.

"Boys, I am sending round to you at once your checks for two thousand dollars, as I agreed. That's about a thousand an hour for this little adventure."

After the howl of delight subsided he went on:

"The Admiral has requested me to turn the submarines over to him to use against the southern squadron of the enemy, now making for San Francisco. I have agreed to do that; and he wants the crews also. That's up to you."

A roar of cheers greeted this statement. Captain Mulray sprang to his feet and shouted:

"We're yours, Cawthorne, hearts, souls an' bodies! Just you lead th' way, an' iv'ry damn Jap or Chinese dreadnaught on th' Pacific'll get th' Omegon paralysis!"

Cawthorne laughed and shook his head. "Can't do it, boys! You can handle the navy all right, but there's an army of the enemy getting ready to cross the Rio Grande. Submarines won't work there, so Kilroth and I are going to put a new round-up device in commission. We'll be ready for your help as soon as you're through with this other little Omegonizing job."

THE END.

ELECTRICAL SHIP PROPULSION.

If the electrical propulsion of a vessel of the United States navy seems a roundabout method of using the energy of steam, the results of a late Swedish experiment show that it should be far from wasteful. The "Mjolner" and the "Mimer" are sister steamers of 2,225 tons displacement each, the former being driven by electric motors fed by steam-turbine generators, while the second boat is fitted with ordinary triple-expansion engines. It was stipulated that, while each vessel should have a speed of 11 knots with engines developing 900

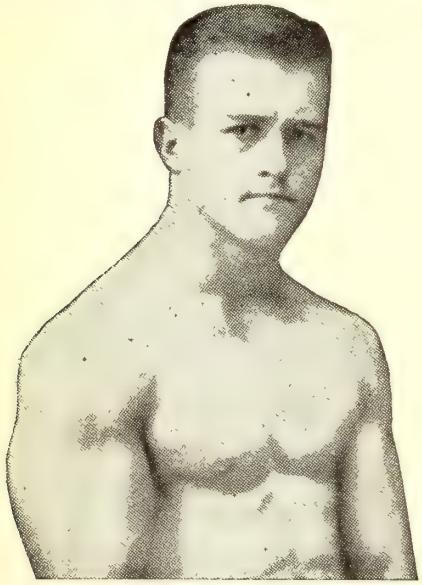
PORCELAIN

"THAT'S OUR BUSINESS"

Standard and Special Shapes, Regardless of How Difficult

We illustrate one hard shape we make. A pair of rolls 7½" long and 1¼" in diameter with 8 holes on ends and middle. They must be perfectly straight and we make them so. It's hard but not for us. We can make your difficult designs also. Send us blue print for quotations.

Union Electrical Porcelain Works



TRENTON, N. J.

"Gains 22 Pounds In 23 Days"

Remarkable Experience of F. Gagnon. Builds Up Weight Wonderfully

"I was all run down to the very bottom," writes F. Gagnon. "I had to quit work I was so weak. Now, thanks to Sargol, I look like a new man. I gained 22 pounds in 23 days."

"Sargol has put 10 pounds on me in 14 days," states W. O. Roberts. "It has made me sleep well, enjoy what I ate and enabled me to work with interest and pleasure."

A PLUMP, STRONG, ROBUST BODY

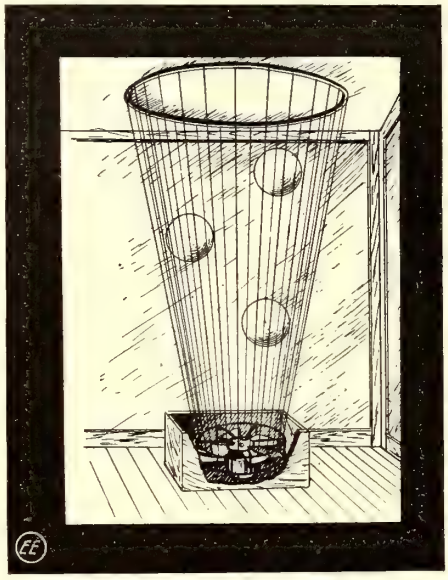
"Before I took Sargol people used to call me 'skinny,' but now my name is changed. My whole body is stout. Have gained 15 pounds and am gaining yet. I look like a new man," declared another man who had just finished the Sargol treatment.

Would you, too, like to quickly put from 10 to 30 lbs. of good, solid, "stay-there" flesh, fat and muscular tissue between your skin and bones?

Don't say it can't be done. Try it. Let us send you free a 50c. package of Sargol and prove what it can do for you.

More than half a million thin men and women have gladly made this test and that Sargol does succeed, does make thin folks fat even where all else has failed, is best proved by the tremendous business we have done. No drastic diet, flesh creams, massages, oils or emulsions, but a simple, harmless home treatment. Cut out the coupon and send for this Free package today, enclosing only 10 cents in silver to help pay postage, packing, etc.

Address The Sargol Co., 847-H Herald Bldg., Binghamton, N. Y. Take Sargol with your meals and watch it work. This will tell the story.



FREE SARGOL COUPON

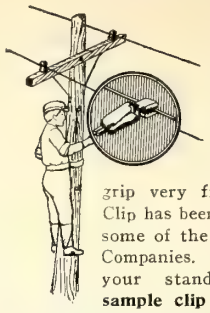
This coupon, with 10c. in silver to help pay postage, packing, etc., and to show good faith, entitles holder to one 50c. package of Sargol Free. Address the Sargol Co., 847-H Herald Bldg., Binghamton, N. Y.

horse-power, the turbo-electrical vessel should use 30 per cent. less fuel than the other. In the trial trip of seven hours, the guaranty for the turbo-electrical vessel was much exceeded, for the engine developed 975 horse-power, the average speed was 11.8 knots, and the saving in coal consumption reached 35 per cent. The steamers are to be used in Swedish coast trade.

SHOW-WINDOW ATTRACTION.

A moving thing in a window is reasonably sure to get a crowd, and it is easy for an electrical dealer to have motion in the windows, says *The Electrical Dealer and Contractor,* and a very good means of providing motion in a window is by means of an electric fan, a small box and a lot of twine. This is illustrated herewith.

Effective Show-Window Attraction—Fan Blows Balloons Upward Continuously.



The drawing shows very plainly how the plan is worked. Lay an electric fan on its back in a small box. Then tie a lot of strings on the box extending them up to a barrel hoop fastened to the top of the background. Inside of the strings put four or five toy balloons. Then start the fan. The balloons will bob up and down and the people will stop and look. They can't help it. They cannot see the fan, and this will give the impression that the balloons are being propelled by some mysterious force.

One merchant who tried this plan painted a letter on each balloon. Together they represented some word. He advertised that he would give a prize to the person who guessed the word. It seemed to him that nearly everybody in town tried to patch the word together from the letters on the balloons as they bobbed up and down with rhythmic regularity.

Try the plan. It is about the easiest and most inexpensive means of supplying attractive motion in windows that has come to our attention in a long time.

Do you realize that, with this issue of 64 pages, at 10 cents, the ELECTRICAL EXPERIMENTER contains the equivalent of 128 pages of ordinary magazine size! It is equal in value to a $2.00 text-book. Don't miss the October number!

Lineman's Test Clips

Universal Test Clips are ideal for the lineman. Because—They make sure contact, fit the hand, never slip, have a very high capacity yet fit in very small places. Side teeth grip very fine wire. Our No. 8 Clip has been adopted as standard by some of the largest Bell Telephone Companies. Make Universal Clips your standard. **Send 15c. for sample clip and complete catalog.**

FOREIGN Stamps Free, 52 different foreign, including China and Venezuela, to all who apply for our high grade approval selections. Send two cent stamp for return postage. Edgewood Stamp Co., Dept. H, Milford, Conn.

WIRELESS

WE make Loose Coupler, 2,500 meter, $5; Tuning Coils, 350 meter, $2. Cliff Mfg. Co., Box 130, Brookfield, Mass.

AUDION Amplifier Hook-up. Marvelous! Uses one Audion only; Wireless Arcs, any size, Poulsen or Collins type; Inductance capacity, Wave length, Chart; Blueprints either one, 20c. H. Winfield Secor, Consulting Engineer, 2040 7th Ave., New York City.

LOOK! New Wireless Invention; 10 cents will bring complete plans how to make. Equity Electric Co., Nogales, Ariz.

Scientific Exchange Columns

UNDOUBTEDLY you have at the present time some things for which you have no further use. Do you wish to sell these things or exchange them for something, for which you have immediate use? There is no surer and quicker way to do this than by advertising your articles in these columns. The **Very** people, the **Only** people, who could possibly have a use for your things read this journal. More than 30,000 interested people will see your ad. It is furthermore the cheapest advertising medium for you in the country.

The rates are: One cent per word (name and address to be counted) minimum space 3 lines. Count about 7 words to the line. **Remittance must accompany all orders.**

We reserve to ourselves the right to refuse any advertisement which we consider misleading or objectionable. Advertisements for the October issue should reach us not later than September 5th.

The Classified Columns of "The Electrical Experimenter" Bring Positive Results.

WILL SWAP—A Savage 22-caliber 7-shot repeating rifle, also a 32 6-shot double-action revolver. What have you? Henry Priebe, Kent, Ohio.

FOR SALE—Amco 1,800 Meter L. C., 1 loader, 1 F. C. and 1 mineral detector. $5.00. Uriel Myers, Charleston, Mo.

FOR SALE OR TRADE—7,000-meter loose coupler, 1 universal, 3 galena detectors, junior fixed condenser, 1 test buzzer, 1 D. P. D. T. and 1 S. P. D. T. switch, 1 fuse block, 3 lbs. antenium wire, 8 insulators; perfect condition. Prefer motorcycle. Will sell separately. Goods cost $45. H. C. Spencer, 110 Davis St., Syracuse, N. Y.

SALE OR EXCHANGE—Brandes 1,000-ohm receiver, volt-meter K. & D. What have you? Alexander Bollerer, 77 Linwood St., New Britain, Conn.

WIRELESS instruments for sale. Write to Vincent Natalish, Stockbridge, Mass. Box 101.

EXCHANGE—General Electric Hot Wire Meter ($25) for Brandes Transatlantic Phones. Platt, Wentworth St., Bridgeport, Conn.

FOR SALE—Cabinet receiving set in excellent condition. Receives Arlington, Va. Only $10. For further information write Oliver Black, 19 Charles St., Lawrence, Mass.

TO SELL—A 22-inch "Tuning Coil" and Galena Detector. Write Paul Epperlein, 403 East 92d St., New York City.

CARD Press Outfit. New. Cut-making outfit. Take 3A folding Kodak automatic shutter case with strap. W. G. Kulp, R. No. 2, Elizabethtown, Pa.

FOR YOUR CONSIDERATION—Gernsback Variable, cost $4, price $2; Omnigraph $2, price $1; Universal detector $1.50, 75c.; all postpaid. In splendid condition. May exchange. W. R. Cottrell, Prairie City, Iowa.

EXCHANGE — Hawkin's Mechanical Drawing; Belding's Commercial Correspondence; Engineer's Examinations; for **Giant Sounder.** Mark S. Kistler, Centreport, Pa.

HAVE Loose Coupler; want 2,000 phones. Joseph Kennedy, 27 Waverly St., Springfield, Mass.

I WANT to swap a brand new Crystaloi Detector for an Interstate wireless outfit. L. J. Becker, 2924-L, Galveston, Texas.

FOR SALE—1,500-meter bare wire loose coupler, $2.50; also $25 violin and case for $5. Fine shape. Will trade for transformer or other transmitting apparatus. Also Crystaloi Detector, $2; 800-meter tuning coil, $1.25; slide plate variable condenser, 75c.; $7.50 Model Builder Set, $4; 2½-inch film-developing tank, $2. Herman Straab, 41 North 4th, Ironton, Ohio.

I HAVE a valuable idea, but lack money to patent and promote. Will sell or exchange. What do you offer? Write to A. M. Niemi, Van Etten, N. Y.

EXCHANGE OR SALE—2-inch coil, headset, adjustable sending condenser, 7 Edison 150-ampere-hour batteries, telephone generator, detector, 2 gaps, 2 flashlights, 2 motors and 2 wireless switches. Will exchange for good motorcycle motor or sell right. All letters answered. Write Seward E. Owen, Vienna, S. D.

FOR SALE—Receiving and sending wireless set, mounted. Aerial wires, insulators; instruments new. Sacrifice for $15. Sterling, 78 Third Ave., Brooklyn, N. Y.

FIRST Money Order for $9.50 takes new Crystaloi detector, cost $6. Loose coupler, cost $3.50, and single headset, cost $3.55. P. Adams, 96 West Housatonic, Pittsfield, Mass.

FOR SALE OR EXCHANGE — $8 Radiopticon post card projector with acetylene generator. In perfect condition. Will sell for $4. Would exchange for loose coupler, phones, or what have you electrical? Louis Folsom, North Dexter, Maine.

FOR SALE—Practically new, six-shot 32-caliber revolver, with holster. This outfit is in first-class condition. Price $1.60 postpaid. Arthur Haugerud, Scappoose, Ore.

TO SWAP OR SELL—Splitdorf, Type D. Model E Magneto and Dash Coil, costing $50. Good as new. Four 2-quart Leyden Jars, never used. Any of above less than one-half price. E. Alex. Hand, M.D., Walton, N. Y.

FOR SALE—Twelve-inch Spark Coil. Perfect condition. Runs on six cells or 110 volts with Gernsback Electrolytic. Good fluoroscope Gundlach vacuum tube. Sell all for $35. Dr. Martinetti, Orange, N. J.

KODAK wanted. Have Wireless Specialty Phones, banjo, I. C. S. Elec. Eng. course library, lathe, Jewett typewriter, etc. Write me what you have. Young, Union St., Portsmouth, N. H.

It Pays to Read These Columns

209 N. 3d Street, Charleston, Mo.

Gentlemen:—

It may be of interest to you to know that I am now installing 2½ K.W. station at half price; about $25. This certainly proves the worth of your paper; I would not be without it. Two issues of it have saved me $24.80.

(Signed) Uriel Myers.

COMPLETE list of wireless goods for sale or exchange: Enclose stamp. Want 6v. 60-ampere-hour storage battery of reliable make and in good condition, also 6-volt dynamo. A. Leroy Jennison, 83 Russell St., Waltham, Mass.

EXCHANGE—52 feet of flexible No. 8 conduit wire. Also good stepdown Transformer. Want Wireless goods. Oscar Davis, 263 State St., Bangor, Maine.

FOR SALE — Crystaloi Detector, never used, $2.50; 9950 Tuner, 75c.; 10010 Fixed Condenser, 25c.; 8090 Phones, $1.50; Telegraph Key. L. J. Becker, 2924-L, Galveston, Texas.

FOR SALE OR EXCHANGE—One set 8-ounce Spalding's "Navy Special" Championship Boxing Gloves. Will sell cheap or exchange for 3,000-ohm double Headset or Spark Coil. Louis Menier, Room 808, 29 West 39th St., New York City.

HALL 5x7 Reflex Camera and other goods to trade for small dynamo or gas engine. Will pay difference. A. Warfel, Cadiz, Ohio.

FOR EXCHANGE OR SALE—Brand new baseball game, all-steel, excellent condition. Cost $2. What am I offered? Money or electrical goods preferred. S. Jones, 591 Quincy St., Brooklyn, N. Y.

STOP!

We hereby present one of the greatest bargains in electrical literature ever offered.

A complete Volume of the *Electrical Experimenter*, bound in rich, dark green linen, stamped with gold letters at the extraordinary low price of

75c.

Volume contains twelve numbers (from May, 1914, to April, 1915), **240** pages, **350** complete articles, **550** illustrations, **396** questions and answers.

A world of electrical information; the entire electrical Progress for one year; the greatest reference book on current "Wireless"—all at a price as low as the *unbound* copies would bring. Mind you, the book is durably bound with heavy covers. You will be proud to have it in your library. We have only a few hundred copies, therefore be sure and order today. Shipping weight 2 lbs. Add a sufficient amount for postage.

Our New Big 216 PP. Electrical and Wireless CATALOG

IS THE EXPERIMENTER'S REFERENCE BOOK

THE BEST BARGAIN IN THIS MAGAZINE IS

No. 7729.

THE AMCO NAVY TYPE RECEIVING TRANSFORMER

Represents the latest advances made towards the ideal tuner and embodies the greatest degree of perfection yet obtained. No greater value can be secured where accurate selectivity, sensitiveness and finish are desirable. The illustration shown herewith cannot possibly do justice to the instrument itself. The primary winding is enclosed in a cabinet, the sides and top of which are polished hard rubber. Two 15-point switches are mounted on the front. One switch controls the primary in groups of several turns and the other controls one turn at a time. The entire variation of the primary is thus secured by the rotary motion of two knurled knobs rather than the movement of a slider, and may be varied from **1 to 225 turns in steps of one turn at a time.** The windings are especially adapted to long wave lengths. The secondary is wound with green silk covered wire. The ends are HARD RUBBER, turned and polished. Secondary variation is secured by a 12-point switch which makes it possible to secure a very fine adjustment.

PRICE, ONLY $15.00

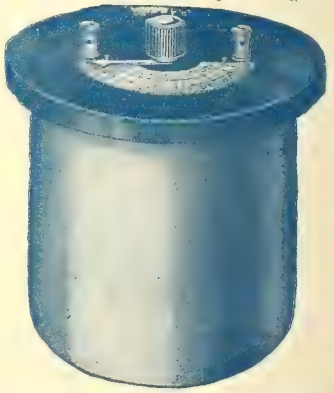
Brandes Wireless Headsets

The "SUPERIOR" Type

Price, Complete, Five Dollars

¶ This is the headset used by Mr. Chas. E. Apgar in conjunction with his special apparatus for making the phonographic records of the Sayville station as described on page 210 in August issue of the Electrical Experimenter. Mr. Apgar chose Brandes Receivers after careful comparative tests with other makes.



Send stamp for catalogue "E" fully describing all our headsets.

C. BRANDES, Inc., Wireless Receiver Specialists

32 UNION SQUARE, NEW YORK

UNUSUAL

The "Albany" Rotary Variable Condenser is unusual insofar as it is an article with a conscience. It combines efficiency and beauty. Considered a real bargain at its regular price of $3.25. For a limited time it will be sold at the unusual price of $2.50.

Note these specifications: The case is one piece of polished aluminum 4" in diameter and 4" high. It may be filled with oil without leakage, and this increases its capacity approximately five times.

There are 31 aluminum plates, 16 stationary and 15 rotating. These are fastened to a polished fibre top which fits tightly over the case. The top is provided with a celluloid scale, pointer, knurled knob and binding posts.

The maximum capacity, without oil, is .003 Mfd.

It is particularly adapted for a series condenser in the primary circuit of a coupler.

After reading the above you must agree with us that we have an unusual article at an unusual price. Send for

No. 102 Albany Condenser at $2.50, postage extra.

Shipping weight, 2 lbs. Delivery from stock. Circular of our complete line on request.

The Wireless Amateur

WE have often had occasion to feel amused at the blank astonishment of the average well-informed European when he first spies the hundreds of aerials which now decorate a multitude of houses in our cities. When we inform the stranger that, according to trustworthy statistics, there are now between 350,000 and 400,000 purely amateur Wireless stations scattered all over the United States, there is no end to his wonder.

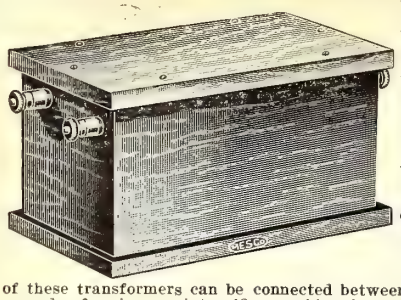
This is not surprising if we consider the fact that the United States to-day is the only country that places practically no restrictions upon the Wireless amateur. In America everybody is allowed to put up a Radio receiving station, and while a license must be obtained for sending messages the regulations are far from severe and any intelligent youth, as a rule, finds it comparatively easy to obtain the coveted license.

Now let us turn to other countries. Of course, during the war in the affected countries no amateur stations are allowed to operate, the penalties for the offenders being extremely severe and usually a long term of imprisonment is meted out to the unlucky operator.

The conditions prevailing before the war and which will presumably prevail again after peace is re-established are briefly these:

Great Britain and its dependencies: No Wireless amateur stations can be erected without the consent of the Postmaster General. In Australia, previous to the war, amateur Wireless was all but suppressed. Of England's colonies Canada probably has the greatest Wireless freedom, although a license from the Postmaster must be obtained. In Great Britain proper, it has been estimated that not more than 2,000 amateur Wireless stations prospered before the war. In France and its colonies and in Belgium the same conditions prevailed as in Great Britain. It seems, however, that the French amateurs, just previous to the outbreak of the war, engaged in a petition to the Government, pleading for greater Radio freedom. Results of the petition are unknown at this time. Of all the foreign amateurs the French are probably the most active. Before the war some 1,500 amateur Wireless stations were known to exist in France and Belgium, according to the best authorities.

In Germany, Austria-Hungary and Russia amateur Wireless is absolutely unknown. There have never been any amateur Radio stations in these countries to the best of our knowledge. The governments of the above countries are exceedingly strict in the transmission of intelligence by Radio telegraphy and no licenses are ever granted, with the exception of those to savants and to a few universities. But even here the restrictions are formidable.



The rest of the world, with the possible exception of a few South American countries where less than 200 stations flourish, measures up poorly as far as the Wireless amateur is concerned. It is believed that outside of the countries named there now exist less than 300 amateur radio stations. Outside the United States there are, therefore, considerably less than 15,000 such stations. In other words, there are in America twenty-five times as many amateur Radio stations as in the entire world. It is, indeed, a surprising result and speaks well for the enterprise of the American experimenters.

Nor can the average European understand of what earthly good the youthful Radio amateur is, for he argues correctly that not all of them can possibly become commercial operators. But he forgets that the average amateur must of needs have a higher intelligence than his card-playing, dance-hall-resorting classmate. Indeed, when your average Radio amateur has mastered all the intricacies of a Wireless set, he has obtained a pretty thorough knowledge of electricity in general. As a rule, most of our electrical industries, big and little, require thoroughly practical young men, the ones who know how to do things. This is where the amateur shines, and nine times out of ten he lands the job over the head of the untrained, theoretical young man.

For this reason American parents, as a rule, encourage their son, for they know that he does not waste his time. The amateur wireless station seems to be a first-class investment.

H. GERNSBACK.

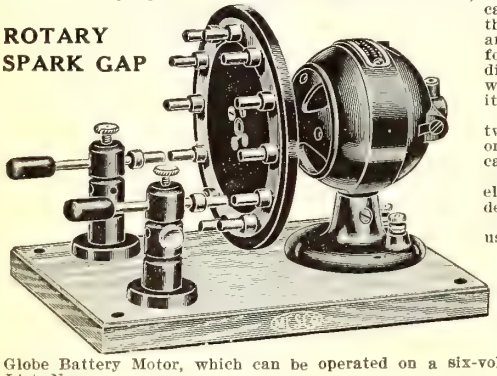
INTENSIFYING TRANSFORMER

This Special Transformer is constructed especially for intensifying in-coming signals.

It can be used for intensifying signals received from any crystal detector by connecting an audion detector on the other side of the transformer winding.

By employing it between two audion detectors signals will be intensified from 10 to 25 times.

As many as three of these transformers can be connected between audion detectors in cascade, forming an intensifier, making it possible to read signals not heard with any single known detector.



No modern wireless station is complete without an intensifier as when it is needed it is wanted bad, so why not provide beforehand.

An intensifier makes possible the use of loose coupling, thus eliminating part of static and other atmospherics. The wireless engineer or operator alone knows the vast interference caused by these unknown phenomena.

Diagram of connections complete with full directions accompany each instrument.

List No. 224 Intensifying Transformer.....Price, **$12.00**

ROTARY SPARK GAP

A **Rotary Spark Gap** is required in every transmitting station by the Federal authorities, for the reason that this type of gap produces a pure wave of low damping decrement. It also increases the efficiency of any transmitting station from 20 to 30 per cent.

This Rotary Spark Gap emits a high musical note, more audible to the human ear, can be heard at greater distances than the note from the stationary type, and cannot be mistaken for static or other atmospheric disturbances, a fault common with the stationary gap due to its low frequency note.

The rotating member has twelve sparking points mounted on a hard rubber disk and is carried on the motor shaft.

Also fitted with two stationary electrodes with special adjusting devices.

The Gap can be successfully used on any of our spark coils or transformers up to and including 1 K. W. capacity.

Our standard Globe Motor is used, which will operate on 110 A. C. or D. C. circuits and attains a speed of 4,500 R.P.M. Also made with our Globe Battery Motor, which can be operated on a six-volt circuit.

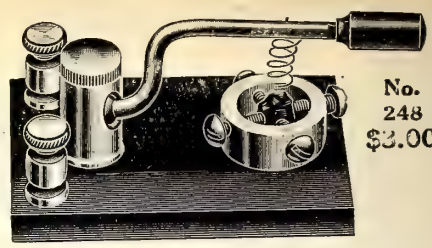
List No.		Price
222	Mesco Rotary Spark Gap, 6 volt	$12.00
223	Mesco Rotary Spark Gap, 110 v., A. C. or D. C.	13.00
216	Rotary Unit only, with two Stationary Electrodes, 1 3/16 in. shaft	5.00

SEND FOR COPY OF OUR

New Wireless Manual No. 9

It contains tables and diagrams, many of which never printed before and is positively the most up-to-date book on wireless yet published.

We make a charge of 10c. for it, for which we give a coupon which amount will be allowed on an order amounting to $1.00 or more.



Send for our Pocket Catalog W 28

It contains over 240 pages, with over 1,000 illustrations, describing in plain, clear language all about everything you need electrically. It is the most complete pocket electrical catalog issued.

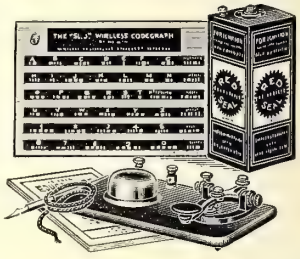
CHICAGO, 114 So. 5th Ave.
ST. LOUIS, 1106 Pine St.
SAN FRANCISCO, 604 Mission St.

UNIVERSAL DETECTOR STAND

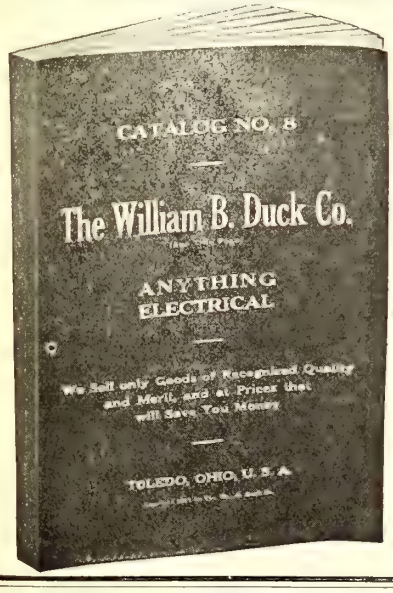
No. 248 $3.00

This **Stand** has a heavy brass cup, with four binding screws, capable of holding crystals up to and including ¾ in. diameter.



A hollow standard encloses a brass ball. Through an opening in the wall, a brass arm with hard rubber handle is secured fast to the ball, making a ball and socket joint, allowing it to be adjusted at any angle or used in any position.

A hole for the introduction of different size wires extends through the arm. A set screw in the side of the arm binds the wire.



Supplied with two binding posts. All mounted on a heavy genuine hard rubber base 2¼x4¼x⅜ in. All metal parts nickel plated. A spring rests on the ball in the hollow standard and sets into a cup under the adjusting screw, so that varying pressures can be had as circumstances require. Remains permanently in adjustment under jars and vibrations of every description.

CODEGRAPH

The **Codegraph Plate** is of metal, with insulated dots and dashes. The Pen is connected in circuit with the Red Seal Dry Battery and the Wireless Practice Set. When the pen is drawn across the dots and dashes it closes the circuit and the buzzer sounds. It is possible to attach a sounder to the outfit and get the telegraph click also. A practical and efficient way of learning wireless and telegraph signals.

List No.		Price
303	Mesco Codegraph Set	$2.50
304	Codegraph Plate, Pen and Book	1.00
342	Practice Set, no Codegraph Plate, Pen or Book	1.50

Vol. III. Whole No. 30 OCTOBER, 1915 Number 6

The Aurora Borealis or the Northern Lights

By H. Winfield Secor

THE Aurora Borealis, or as it is commonly known, the *Northern Lights,* constitutes one of those great scientific problems which bid fair to puzzle the keenest wits in their solution for years to come. Those of us who live in the temperate or tropical zones of the earth have probably never witnessed to any great extent, the truly indescribable and marvelously beautiful color effects, produced by the Aurora Borealis, or also by the Aurora Australis. When these spectacular effects of nature are seen in the neighborhood of the North Pole, or at least in that direction, they are known as the "Aurora Borealis." When seen in the vicinity of the South Pole or in that direction (with respect to the observer's location), they are termed the "Aurora Australis."

The word Aurora Borealis (and referring to the northern polar lights, frequently observable in the heavens), was first used by Gassendi in the year 1621, or so our science books tell us.

Up until the last century there were many wild tales published in various parts of the world with respect to the Aurora Borealis and as to what it looked like, as well as to the other physical properties manifested by this little understood phenomenon occurring in nature. It is generally conceded to-day to be an electrical discharge taking place through the highly rarefied upper atmospheric strata surrounding the earth. Although many writers have claimed that there is a distinct sound accompanying such Auroral discharges or demonstrations, it is pointed out in most reliable scientific works on the subject that there is no sound noticeable when these Auroral effects take place, or at least no sound that can be attributable directly to them. Several explorers and scientists who have studied this phenomenon closely mention distinctly that sounds have been heard simultaneously when these Auroral effects occur, but in many cases, and quite possibly in all cases, therefore, these sounds were found to emanate from such causes as the shifting of large ice fields, the continual changing of large snow deposits or other minor sources.

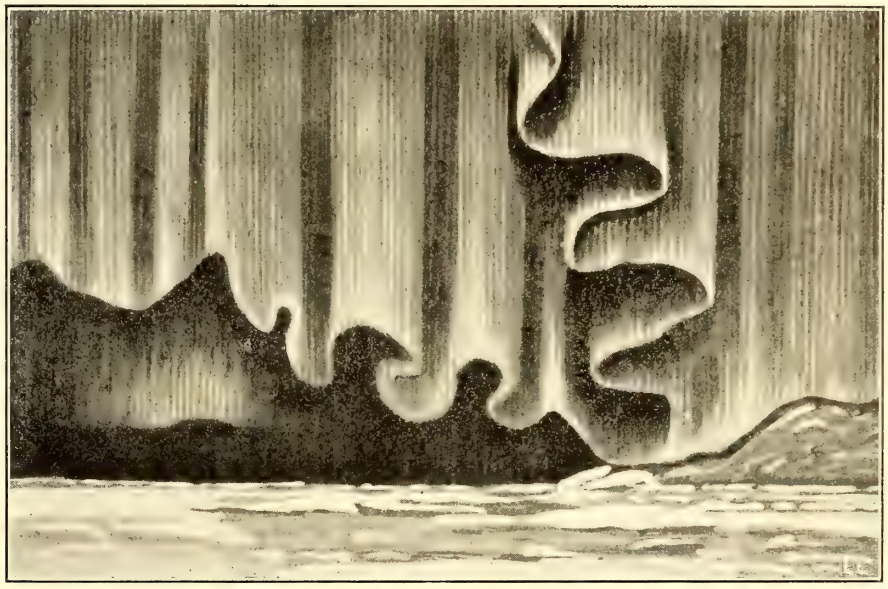

Fig. 1. Beautiful Ribbon Effect of Aurora Borealis When Viewed at Close Range in Northern Countries.

As regards the matter of any distinct odor or smell noticeable from the Aurora Borealis effect some authorities have claimed that there is discernible a distinctly irritating odor similar to that produced from "ozone," or practically speaking the same as we all have noticed after a heavy thunder storm has passed. The "ozone" in this case is due to the lightning discharges striking through the atmosphere and purifying same. Ozone is thought to be a certain form of oxygen.

Contrary to general belief the strength of the light given forth by the largest Auroras is much inferior to that of the full moon. This fact is mentioned by those who have studied the Aurora in the Northern regions at close range. Tests carried out by reading a printed page, etc., prove that generally speaking the maximum light from the Aurora Borealis rarely exceeds that of the moon in its first quarter, which is, of course, quite weak, or in other words, reading an ordinary book page was just possible. The duration of the Aurora display may be but a fraction of an hour or it sometimes exists for several hours, fluctuating all the while.

The color of the Aurora Borealis is one of the least understood at the present day by the layman. In general it is usually composed of more or less vivid red, yellow and green shades. The front cover illustration, reproduced from an oil painting especially painted for the *Electrical Experimenter,* shows some of the enchanting beauties of this wonderful display produced by nature and which has been viewed only in all its magnificent pristine glory by very few men indeed, as such a worthwhile view is obtained only by making a pilgrimage to the regions adjacent to the North Pole.

The above mentioned painting is the only one in existence to our knowledge showing the Aurora Borealis in its true colors. It was originally conceived by Mr. H. Gernsback who is responsible for its accuracy; it required several weeks of careful as well as painstaking work in order to enable the talented artist, Mr. Thom. N. Wrenn, to start the painting. Several experts on the

THE ELECTRICAL EXPERIMENTER is published on the 15th of each month at 233 Fulton Street, New York. There are 12 numbers per year. The subscription price is $1.00 a year in U. S. and possessions. Canada and foreign countries, $1.50 a year. U. S. coin as well as U. S. stamps accepted (no foreign coins or stamps). Single copies, 10 cents each. A sample copy will be sent gratis on request. Checks and money orders should be drawn to order of THE EXPERIMENTER PUBLISHING CO., INC. If you change your address notify us promptly, in order that copies are not miscarried or lost. *A green wrapper indicates expiration.*

All communications and contributions to this journal should be addressed to: Editor, THE ELECTRICAL EXPERIMENTER, 233 Fulton Street, New York. Unaccepted contributions cannot be returned unless full return postage has been included. ALL accepted contributions are paid for on publication. A special rate is paid for novel experiments; good photographs accompanying them are highly desirable.

THE ELECTRICAL EXPERIMENTER. Monthly. Entered as second-class matter at the New York Post Office, March 1, 1915, under Act of Congress of March 3, 1879. Title registered U. S. Patent Office. Aurora including Mr. Arctowsky, of New York, were consulted during that time.

A good idea as to the general appearance of the Aurora is best had by quoting a few words from Alexander Von Humboldt, the famous explorer, who had the good fortune to witness a number of excellent Auroras at close range.

Fig. 2. The Aurora Borealis Resembles a Mighty Curtain Flapping in the Breeze.

Says this scientist, "Consider that the sky becomes at first slightly overcast and a little later a dark segment seems to form in the firmament overhead. This dark segment passes from the form of a dark shadowy cloud into a beautiful brown or violet shade. A broad, brightly luminous arch is noted, which slightly encircles the dark segment. This arch remains sometimes for hours together, flashing and kindling in a marvelous and ever varying series of undulations before rays and streamers branch out from it, shooting upward toward the zenith. The more intensive the discharge of the Northern Lights, the more bright is the play of colors, furthered by the variety graduation from violet and bluish white to green and crimson. If the observer is fortunate, as some have been, he may perchance see the most wonderful sight possible for any human, or that known as the *Crown of the Northern Lights*. This effect is caused by the rays or streamers darting upward from the curtain-like band, closing in, so as to form a *bowl* or *halo*. It is practically impossible to artificially produce or describe in words the truly magnificent effect thus attained by nature's handiwork and which probably will never be duplicated by man artificially, or at least never on any such grand scale, as occurs in the Northermost regions of the earth, which few, indeed, ever visit."

The illustrations at Figs. 1 and 2 give a fair idea as to how the Aurora Borealis extends upwards into the sky in the form of a ribbon or waving sheet. This ribbon formation is made up of a myriad of flashes or stripes, so to speak, which are continually changing in intensity and color value, being of a bright red at their base, yellow at the center and green at the top usually. When viewed through the "spectroscope," the light of the Northern Aurora appears a vivid green and its wave length has been established to have a value of 5,570 standard units.

Sir William Ramsay, the noted English scientist, made a number of laboratory tests some time ago with various gases, notably Krypton. When electric discharges were passed through this gas, there was noted, when viewing it through a spectroscope, a *vivid green light*, similar to that produced by the Aurora Borealis, and its wave length was ascertained to be 5,570.5 standard units. On the strength of this phenomenon Sir William Ramsay believes that the Aurora seen in nature may undoubtedly be produced by electrical discharges (in the upper rarefied atmosphere of the earth) and passing through a gas in which Krypton is present to a large extent.

As regards the scientific theory covering the possible nature of the phenomenon known as the Aurora Borealis, it may be said that practically all of these now depend upon some electrical discharge action for their basis. In fact, as early as 1714, Halley, the famous astronomer, hazarded a guess that the Aurora Borealis was a magnetic phenomenon, due to the electrical charge existing on the earth and also in the air above it.

There are two principal theories now worth considering which endeavor to explain the whyfore and the where of the Aurora Borealis. One of these is that due to Prof. Birkeland, of Christiania, Norway, and the other comes from Prof. Svante Arrhenius, of Stockholm, Sweden.

To elucidate, it may be said that we have long known that *violet light rays*, and particularly the invisible rays of the ordinary spectrum beyond the violet (which are easily detected by photographic means), possess the property of discharging a negatively electrified body. It is suggested by Prof. Birkeland that the spots on the sun are caused by solar eruptions, and that the sun is then caused to give forth an extraordinary amount of negatively charged corpuscles, not unlike those which constitute the cathode rays. These rays are similar to those utilized for surgical practises in taking X-Ray pictures of the body.

Prof. Birkeland then supposes that such corpuscles are "sucked" into the earth's *magnetic poles*, giving rise to vortices or whirlpools of electric current in the upper strata of the atmosphere. As is well known, such rays can, of course, be deflected by a magnet. Also the presence of large solar or "sun spots" is invariably accompanied by powerful magnetic storms on the earth, as they are termed, and which often cause trouble on telegraph and other circuits over many widely scattered parts of our globe. Also in conjunction with these large solar spots and magnetic storms there are invariably produced very brilliant Aurorae.

Prof. Arrhenius believes that the corpuscles emitted by the sun are not inconceivably minute bodies, but that they do have an appreciable size. For instance, let us say they are 1/1,000 millimeter or 1/25,000 inch in diameter. Furthermore, that these corpuscles are expelled from the sun by the repulsive action of radiant light. Also that such radiant light in thus capable of propagating or thrusting particles out into space in spite of the enormous gravitational pull of the solar planet. This latter fact has been demonstrated a number of times in the laboratory, viz., that it is possible for light to exert a distinct force. Again, Profs. Nichols and Hull have experimentally proved and demonstrated that light does exert pressure to a very marked extent, relatively speaking, and therefore there seems to be nothing inconsistent with Arrhenius's hypothesis.

Whether we like to accept the theories of Birkeland or Arrhenius as correct or not, it does seem quite possible that negatively electrified gaseous molecules are present in the upper strata of the atmosphere surrounding the earth. Also it seems quite likely that these molecules receive their electric charge most easily where they are most exposed to a vertical sun. In other words, this would be at the equator, or nearly so. These upper aerial currents, so to speak (and according to the theory of Prof. James Thomson), will carry these and other molecules towards the earth's magnetic poles, designated as the North and South Poles, respectively. These molecular streams would move spirally northward and southward with an easterly trend. As they approach the vicinity of the magnetic poles of the earth, their number per unit area would quite obviously be greatly increased, owing to the fact that the terrestrial parallels of altitude degrees grow less in circumference, the closer they are to the "poles." It can also be expected, we are led to believe, that before the magnetic "poles" themselves are reached the potential of the upper air should increase to so marked an extent as to produce a distinctly apparent *luminous electric discharge*. This luminous discharge moreover being in the form of a ring or halo about the magnetic poles of the earth. This particular fact has been noticed by most of the explorers and investigators of the Aurora Borealis. It is this ring or

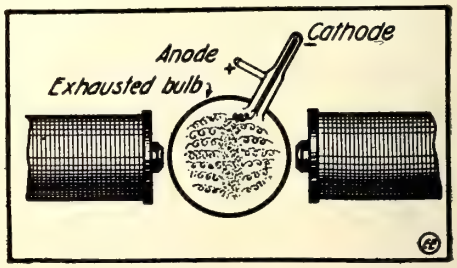

Fig. 3. Producing an Artificial "Aurora Borealis" in the Laboratory.

halo, which we see as an arch in the sky from most ordinary view points, attainable by the average observer.

Figs. 1 and 2 show this *arch effect* that some travelers in Northern regions have had the good fortune to see. These curtains of fire forming the Aurora rise upward and in the course of a short space of time they would close in so as to form a parabola or bowl formation. Also it was noted that the axial center of this bowl formation was the *magnetic pole* of the

earth. A number of mathematical calculations were made in order to check this, as well as the usual observations as taken by regular explorer's instruments.

Prof. Paulsen classes the Aurorae into two divisions. Those considered in the "first class" are those which are widely extended in their formation and also quite steady. They show no streamers worth mentioning. Generally speaking, they tend to rise slowly toward the zenith, and they do not affect the magnetic or compass needle appreciably. An Aurora of this type usually appears in the form of an arch or a multitude of arches. Extended regions of the Arctic and Antarctic skies often glow with a faint light, like translucent clouds. These luminous masses are very often observed 1,000 feet above the ground.

In the "second class" in the category of Aurorae may be mentioned those characterized by streamers or very distinct rays, which may be either sharply separated or they may blend at the bottom, presenting the appearance of mighty curtains, flapping gently, now rapidly, in the breeze.

It has been noted that these rays are invariably parallel with the magnetic or compass needle and when viewed perspectively, they appear to diverge from the center of a radially striped corona. Aurorae of this class are not steady, but are traversed by a series of waves, as they rise from the Northern horizon and also they deflect the compass needle to the east, but after passing the zenith they cause a westward deviation of same. From these observations, Prof. Paulsen is inclined to believe that these streamers are only rays in which negative electric charges move downward toward the earth itself.

As our illustrations indicate, the Aurora Borealis does not start from the very edge of the horizon proper, but it begins at a considerable distance above the earth. The altitude of the base of the arches formed by the *Aurora ribbon*, if we may so call it, has been measured in various ways a number of times by explorers and others making a study of the subject. From various calculations by means of trigonometry and geometry and also by measurements made direct with surveying instruments, the average altitude of the arch above the earth's surface has been found to vary from 20 to 100 miles. Perhaps the highest altitudes that have been deduced, says Alfred Angot, in his excellent work on the subject are the following: as measured by Dalton, 150 miles; Loomis, 400 to 600 miles; Bergman, 468 miles; Boskovitch, 320; Fournerin, 1,006; Twining, 1,100 miles; Boller, 1,243 miles.

The upper altitude of these arches, of course, is naturally considerably higher, depending upon the magnitude of the particular Aurora observed.

Regarding the periodicity of the Aurora Borealis it may be said that for one thing it occurs as intimated previously, with every recurrence of large sun spots. Finally and in spite of its apparent irregularity, the Aurora Borealis seems to follow a well-established routine as to its occurrence and recurrence. The periods fairly well established for its appearance may be summed up as follows:

The diurnal period, the annual period and the period of a little more than 11 years. Among the occurrence periods not exactly known, but of which the existence seems to be proven, there is one of about 28 to 30 days and another of about 55½ years. Other occurrence periods have been surmised and mentioned by different authorities and investigators, especially a period of about 220 years, but they seem rather doubtful.

(*Continued on page* 300.)

Wireless and Telephone Find Extensive Use in European Armies

Wireless telegraphy, as well as wire telegraphy and telephony, has found very extended application in the vast armies now battling over the face of Europe. It is surprising how quickly communication by telegraph, telephone or radio can be established between widely extended points of a mobile army. The telegraph and telephone wires are usually, in this case, let out from a reel carried on horseback, the horse also carrying a signal corps engineer.

Photos by Paul Thompson.

Above: Modern Wireless "Cart" Set in Use by British Army in the Present Terrific European Conflict.

Below: German "Telephone" Station in Use at Advanced Posts in France.

It goes without saying that if it were not for the rapid and far-reaching means of communication now available, thanks to electricity, the rapid movement of troops could never be attempted with the success now attending such manoeuvres under actual battle conditions, as demonstrated time and again by the Germans as well as by the Allies' forces.

Our first photograph shows a modern wireless "cart" set as used in the British army. These sets are very compact and can be unpacked and set up, ready for operation in transmitting radiograms over sections of several hundred miles, in a few minutes' time.

An oil or a gasoline engine is usually employed to drive an alternating-current generator, and the transformers in the radio transmitting set are thus supplied with current. These sets, as here shown, are usually rated at 1½ to 2 kw. and utilize a collapsible steel or wooden mast having a total height of 80 to 90 feet.

The second illustration shows the field "wire" telephone apparatus in actual use by the signal corps of the German army. This particular photograph was taken at one of the outlying advance posts of the German army near the Aisne. These telephone stations are indicated by a large letter "T" hung on the tree, as perceived. This is for the guidance only, of course, of members of the local regiment to which the instruments belong.

As may be seen, the apparatus is quite heavy in its make-up, and it is extremely necessary that such apparatus shall be very rugged, so as to withstand the severe wear and tear of military requirements. It

EXPORTERS ARE TOLD TO USE WIRELESS.

The American State Department, through the Atlanta Chamber of Commerce, recently notified Southern exporters to handle their foreign communications by wireless telegraphy to avoid the strict censorship which the belligerent nations have maintained on all cablegrams from the United States since the outbreak of the war.

This information was sent from Washington by Second Assistant Secretary of State Alvey A. Adee, following a protest from the chamber recently that a number of Atlanta exporting houses had been unable to communicate with their foreign agents on commercial matters by cablegram.

It has been advised by the State Department that the Postal Telegraph lines be used when wireless messages are sent via the Sayville radio station, and that the Western Union wires be used in the transmission of air messages from the Tuckerton radio station.

We want to buy May. '13, Oct., '13, and Jan., '14, copies "E. E." Address the Editor.

Baron Münchhausen's New Scientific Adventures

By Hugo Gernsback

Münchhausen Departs for the Planet Mars

ONCE upon a time a grouchy old gentleman with a grievance for fiction writers, presumably because the latter received more emoluments for their stuff than the former for his poetry, thus vented his resentment in immortal song:

"'Tis strange, but true; for truth is always strange—stranger than fiction."

From this some coarse soul, totally oblivious of any poetic infection whatsoever, took it upon himself to mutilate the above passage of one of Lord Byron's poems and taught us unsuspecting mortals to hawk, parrot-wise, ever after until the end of fiction, thusly: "Truth is stranger than fiction!"

With all due regard to the memory and genius of Byron, I, I. M. Alier, a citizen of a free country, take it upon myself to correct his Lordship at this late and quarrelsome date, to wit:

"There is no fiction."

If, as often—no, always—has been proved that the most violent fiction at some time or other invariably comes true, then by all proceeds of modern logic, there cannot be such a thing as fiction. It simply does not exist. This brings us face to face with the startling result that if fiction always comes true some time or other, why then, bless their dear souls, all fiction writers must be prophets!! Hurrah for the F. W.!! But hold on, boys; don't let our enthusiasm run away with us on a Ford. The spark plug has run afoul somewhere. While it's nice to be a prophet, don't you forget that a prophet is never, never recognized in his own country. Thus the New Testament teaches; so I think it will be safer for all F. W. to remain F. W., rather than to be honorless prophets.

However, that is not what I had in mind when I started—it's so hard for me to say what I mean, and a good deal harder for me to keep my thoughts running on the track. They ramble from one nothingness into another. My mind in that respect is a good deal like a one-eyed, religious old cow on a pasture. She eats up whatever she sees alongside of her, but when she finally turns around she perceives with astonishment that there is still a whole lot to graze on the other side; so she steers around to starboard and returns to her original starting point.

But I am rambling again. So let's return to the original starting point.

Seriously speaking, and by way of emphasizing how much stranger truth is than fiction, I have but to point to Jules Verne's famous stories. When 45 years ago he wrote *"Twenty Thousand Leagues Under the Sea"* no one took him serious. It is doubtful whether he himself believed that the submarine which he invented in that story would ever become practical. It was just fiction. Yet 45 years later we see how a submarine, almost exactly as his vivid as well as prophetic mind conceived it, down to the most minute detail, emerges from a German harbor and travels under its own power over a distance of 4,000 miles, through the North Sea, the English Channel, down the Atlantic, through the entire length of the Mediterranean and up through the Dardanelles to Constantinople! And by way of diversion it manages to sink several battleships of the enemy by means of its torpedoes. Now, bold as he was, Jules Verne never conceived such an "impossible thing," and while his famous *Nautilus* was equipped with almost every other modern submarine necessity, the infernal automobile-torpedo was missing. Truth is indeed very much stranger than fiction. Hundreds of similar instances could be cited, but lack of space prohibits it; besides, I mustn't ramble!*

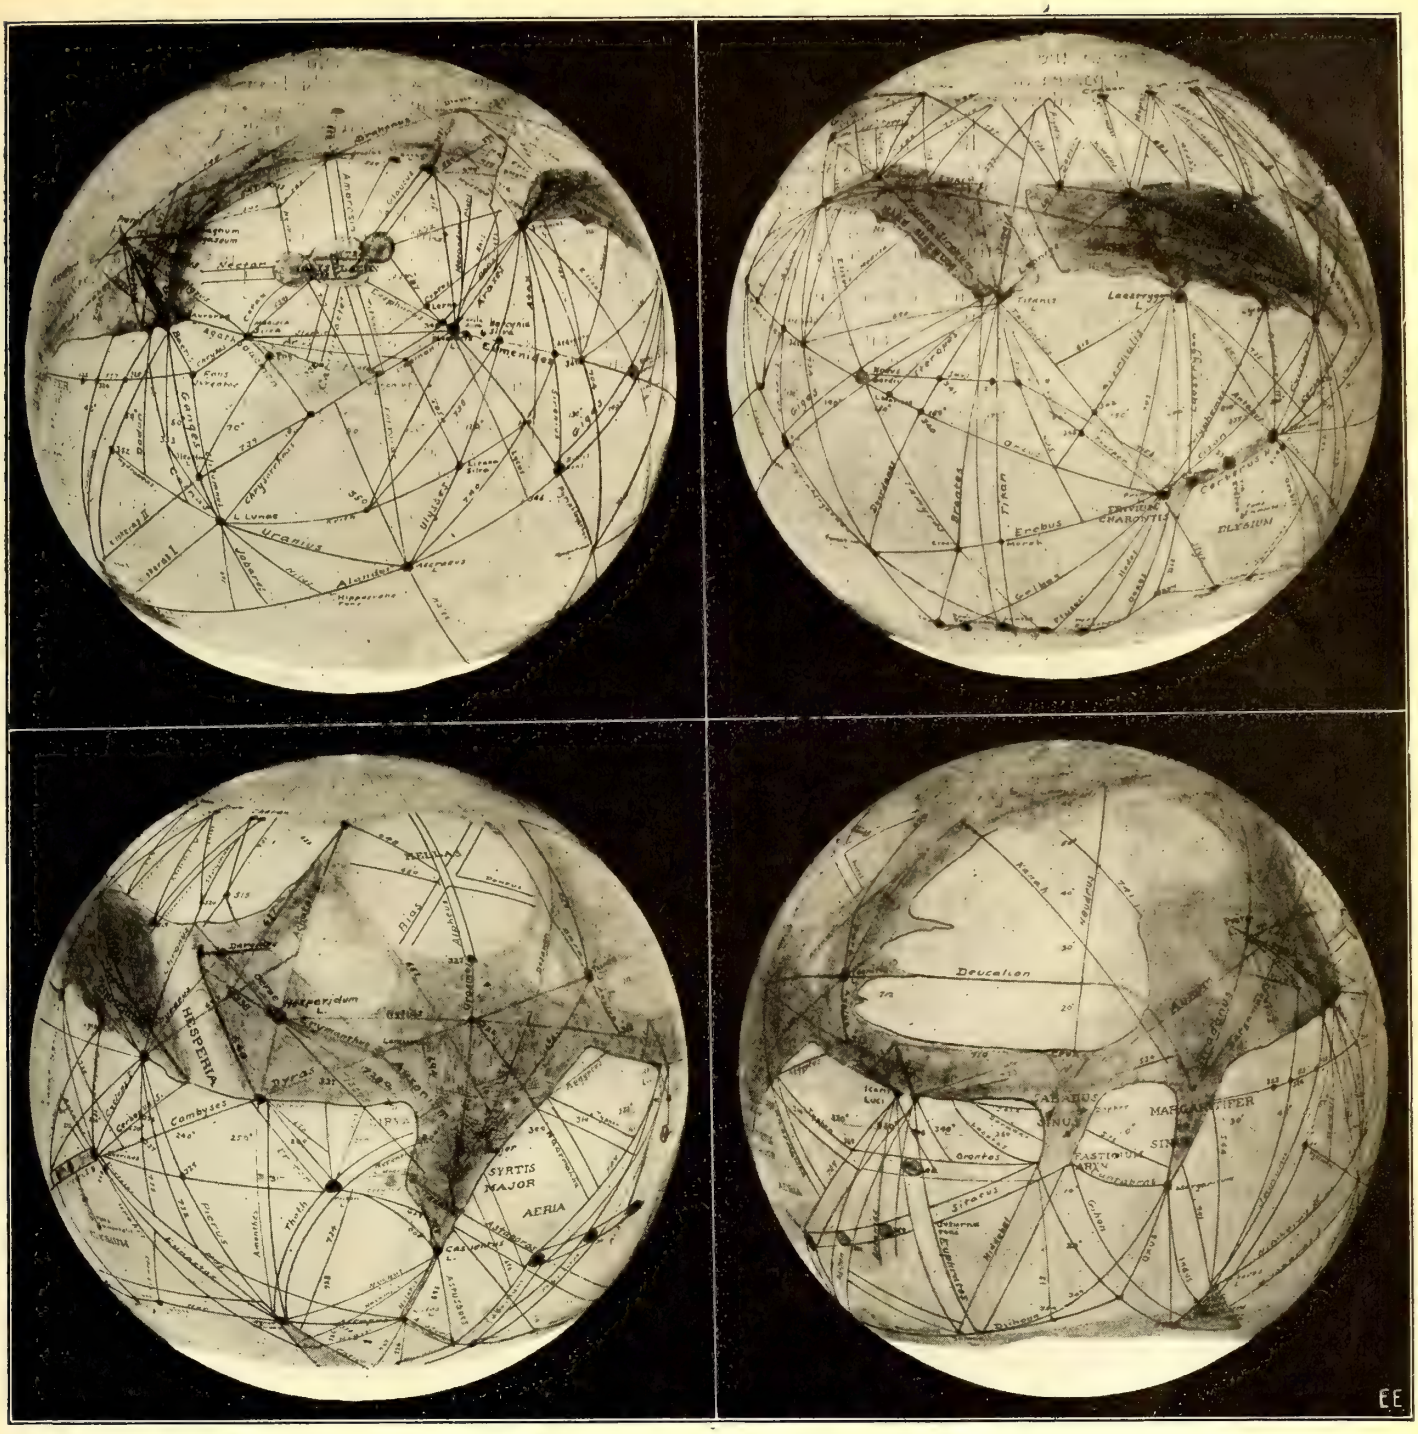
Münchhausen, as will be remembered, had explained the mysteries of the moon to me, and he had also mentioned the great danger of falling meteors, which had been increasing alarmingly in number for some time. †The moon's attenuated atmosphere offered no protection from meteors, as did the earth's thick air. But few meteors ever reach the surface of the earth; the colossal friction between the meteor and the air ignites the former and most of it falls down on the earth as a fine dust. The burning of the meteors represents the shooting stars we see. On the moon, however, the meteors crash down bodily, causing tremendous havoc, and this terrible bombardment goes on forever without letup.† Consequently, when Baron Münchhausen stopped short that evening in the midst of a sentence, I naturally was alarmed not a little. Great, therefore, was my joy when, sitting before my radio set the next evening, 'phones clapped tight over my ears, my eyes glued on the clock, the familiar high, whining spark suddenly reverberated in my ears at the stroke of 11 o'clock.

It was Münchhausen. But his usual sonorous voice to-night had an unfamiliar metallic timbre that puzzled me greatly; in a short time, however, the mystery was cleared, and this is what poured in my astonished ears:

"My dear Alier. No doubt you thought I had been killed by a meteor last night. Well, as you Americans put it, I had indeed 'a close shave.' A meteor crashed down on my aerial 50 feet from where I was sitting; it of course went up in smoke—metal vapor, to be correct—due to the tremendous heat generated by the impact of the meteor on the granite rocks. The whole meteor itself went up in a fiery cloud of red vapor and I was blown headlong a distance of over 50 feet, right down into the mouth of a giant crater, by the colossal resulting blast of the concussion.

"Now, this long-extinct crater is a very deep one; how deep I was soon to learn! I went down head first and kept on falling at a terrible rate of speed. I must have been falling down that awful abyss what seemed to me like hours. As I kept on plunging down I was gloomily reflecting what an inglorious death it was to die down at the bottom of an unromantic crater on a dead and dried-up moon. I thought of many things, when I suddenly became conscious of a terrific cold. Call it instinct or presence of mind, as soon as I had started on my downward journey I had jerked my body in such a manner as to righten it; in other words, after a few attempts I succeeded in falling feet down. It was indeed a fortunate circumstance that the sun was almost directly overhead the crater, for it saved me the anguish of plunging down into a pitch-black abyss. While it was of course not as light as at the top, still I could see where I was falling, and that was at least some consolation. Thus, when I glanced down in the direction of my feet after a while, I am sure that my heart, which had stopped beating, stood still entirely for some seconds. It took me a few seconds to collect my bewildered senses, for this is what I had seen:

"The crater had no bottom at all, but went right through to the center of the moon, where it connected with another crater, *which went to the opposite side of the moon.* I knew this must be so because when I had looked down I had seen several stars shining through brilliantly from the night side of the moon. Then the awful truth flashed through me and I almost swooned. *I was falling through the whole length of the moon!* I had been in many tight quarters before during my somewhat exciting career, but this experience indeed bade well to be the inglorious end of my adventurous life. However, my far-famed presence of mind and my cool head soon asserted themselves, as was naturally to be expected of me.



"I knew the diameter of the moon to be

"THERE *are more things in heaven and earth, Horatio, than are dreamt of in your philosophy."* **So sings Shakespeare. One of these "things in heaven" is the Planet Mars, the most fascinating, the most astounding revelation to the feeble human intelligence. Shakespeare, the master of the drama, never conceived anything like a drama of an entire world—millions of intelligent beings—fighting a heroic battle, a battle for existence. Yet this drama was going on right before his very eyes, but 35 million miles away; for the Martians have been fighting for water ages ago, and the available supply becomes smaller each year.**

There is nothing more inspiring, nothing more gripping to the imagination, than this wonderful battle between organized intelligence on one side and unrelenting nature on the other.

Mr. Münchhausen's scientific lecture gives you the latest facts—now almost universally believed—about Mars. You can spend no better half hour than turning your mind from your humdrum existence towards a subject which is as absorbing as it is lofty in its grandeur.

*In order to distinguish facts from fiction in this instalment, all statements containing actual scientific facts will be enclosed between two † marks.—AUTHOR.

Four different views of the planet Mars. As Mars turns on its axis once every 24 hours the same as the earth, we are enabled to see the entire surface of the Martian globe during that time. The four views, as shown, are therefore taken six hours apart from each other. These pictures were made during the last "opposition" in 1911, when Mars was some 47 million miles distant from the earth. It never comes nearer than 35 million miles to the earth. In 1924 the two planets will be but 36 million miles apart. In the views shown *the top is south, the bottom north,* for through the telescope all objects are turned upside down. The white patch at the bottom is the north Polar snow cap, the southern cap is not in evidence for it has melted already. The melted water has been conducted equatorward by the "canals." Note that the canals run through the dark areas, which are not oceans therefore, but land with vegetation. The light areas are deserts. Nearly all canals are perfectly straight, the ones near the edges of the pictures, appear curved only because we are looking on a globe and not on a plane surface.

2,164 miles. A quick mental calculation proved that it would take my falling body about 24 minutes to reach the center of the moon. As there was nothing to stop my fall, I must naturally continue to fall, due to the tremendous momentum acquired, till my body would *almost* emerge at the opposite side of the moon at the mouth of the other crater. At this point my speed would be zero and I would have fallen for 48 minutes. If I could not manage then to grasp a projecting rock I would commence to fall back again toward the center of the moon. I reasoned that once more my momentum would carry me past the center and I would then be *almost* carried to the mouth of the opposite crater—my original starting point.

"I say almost, for the friction of my body against the air would tend to retard my fall. If at this point, where my speed was again zero, I could not succeed in taking hold of a projecting rock of the crater's side I would begin to fall down once more, the same as before. I would then continue falling back and forward exactly like a bouncing ball, each time, however—just like a rubber ball—a little less than on the previous plunge. Thus my drops would become of shorter and shorter duration, and finally I would fall no more.

"As I had mentioned before, the sun was almost overhead, shining down into the crater. I also remembered that it was almost exactly 12 o'clock midnight, terrestrial time, when the meteor smashed my aerial; this, then, was the time I started on my remarkable journey into the bowels of the moon. With a tremendous effort I pulled out my chronometer and noted that it was 12.23 a. m. In another minute I would fly past the center of the moon. Looking about, I saw in the uncertain light that I went whizzing through an immense hollow, proving to me that the center of the moon was far from solid, due no doubt to the centrifugal force of the moon at the time when it had not solidified, some millions of years ago. I estimated later that the moon was an immense hollow sphere with a solid crust about 500 miles thick. By way of a homely comparison, the moon therefore must be a hollow globe

like a rubber ball. Like the latter, it is filled inside with air, while its crust can be compared to the rubber of the ball.

"In another minute I had passed the center and was now dropping toward the other side of the moon. If I continued falling in my present position I must naturally emerge at the opposite side with my feet toward the sky, as a little reflection will reveal to you. So once more I jerked my body about, and I was now falling *'up,'* with my head at the top, my feet pointing to the sun. At the end of another 24 minutes I could feel my body slowing up from the terrific speed. As the crater at this side of the moon was fortunately rather narrow, I found little difficulty in reaching for a projecting rock as soon as my plunge had come to a dead stop. I held on for dear life and clambered up a narrow ledge, where I fell down exhausted and panting from my dreadful experience.

"My sensations in falling through 2,164 miles of space, going over 16 miles per second at the center of the moon, you would, of course, like to know. Well, the first minute it is rather unpleasant. Highly so. The place where your stomach should be by right is one vast area of nausea. But once you become accustomed to it it becomes bearable, for there is nothing else to do. You might think that the rush of air would kill you in a few seconds, or else draw all the air out of your lungs, thus asphyxiating you. Neither is the case, for the air is so thin on the moon that the rush is not so terrific as it would be on earth. Also, by keeping the mouth tightly shut and breathing—with difficulty, it is true, through the nose—one does not die in 48 minutes. The friction of the air against my body did not ignite the latter either, with a consequent burning of my dear self. For, as I told you some time ago, the temperature inside of the moon is near the absolute zero, the awful cold of the stellar world. But neither did I freeze to death, for the simple reason that the friction of my body through the attenuated air was just sufficient to heat me up enough so as to keep me comfortable. Thus you see that if it had not been so cold I would have burned up; and vice versa, if the friction of the air against my body had not heated it, I would have frozen to death long before reaching the center of the moon. Then, too, another important point to consider is that on the moon, as explained previously, my body weighed but 27 pounds, against 170 pounds on earth.* This is, of course, a rather small weight, and for that reason my fall was not so terrible as if my body had weighed 170 pounds, as on earth. For that reason, too, I was not attracted so much to the sides of the crater as I would have been if my weight had been greater. Also it was fortunate that the two craters widened out considerably the further down they went into the moon's interior. As a matter of fact, the 'hole' of each crater at no point was less than three miles in diameter. This was indeed very lucky for me, for the following reason:

†"If we drop a stone in a very deep and narrow shaft, as has been shown experimentally on earth, this stone will never reach the bottom. Instead, *it will bury itself into the eastern wall* of the shaft long before reaching bottom, providing the shaft is deep enough. The explanation is that the earth rotates on its axis from west to east at a speed of 1,524 feet per second at the equator. Thus it is apparent that the earth revolves quicker than the stone can fall in a few seconds.* It therefore intercepts the stone's flight, with the result that the stone must of necessity strike the eastern wall of the shaft. This phenomenon is termed 'the falling of a body toward east.'†

"Now, precisely the same condition exists on the moon, of course. Fortunately, I started falling at the western side of the crater, but as the latter was so wide I never came near enough to its eastern wall to hit it. Likewise the other crater, at the opposite side of the moon, measured some four miles in diameter and, while I finally did reach the eastern wall, my flight had come to an end as explained already. Indeed, nature favored me all through, for the moon rotates with a velocity of but 15⅓ feet per second at its equator, against a like speed of 1,524 feet of the earth. For this reason there was no danger that my body would collide with the sides of the crater somewhere in the interior of the moon, for my flight was far more rapid than the speed of the moon's rotation on its axis.

"But in the meanwhile my troubles were far from being terminated. No sooner had I regained my breath than I became conscious of the terrible cold; for I was now but a few feet from the surface of the moon, but on that side which was turned away from the sun, where nothing but icy cold, darkness and desolation reign. Aside from this, I was some 2,160 miles away from Flitternix, my companion, and our 'Interstellar.' Walking around half of the moon was out of the question; neither could I stay where I was without freezing to death. So I climbed up to the surface of the moon with considerable effort. Then by aid of the starlight I ran rapidly around to the western side of the crater, for I had to run in order to keep warm. After having obtained my bearings by aid of the stellar constellations, to make sure that I was at the western side of the crater, I took a deep breath, looked down in the abyss through which the sun was shining from the other side, and dived head down into space once more.

"You see, I had reasoned that it was far better to attempt the flying journey through the moon once more than to perish with the cold on the dark side of the moon. Besides, I had experience now and, having been successful once, it was natural for me to expect success again. I had nothing whatever to lose, but everything to gain.

"My first experience was repeated without any incident; furthermore, I calculated that I should land at the eastern wall of the far crater within 48 minutes if everything ran smoothly. But I had left our good old sun out of my calculations. You see, the gravitational attraction of the sun controlled the fall of my body in the same proportion as it controls the rotation of the moon and the earth, as well as the other planets. I mentioned how in my former flight I had risen to the top of the moon; as a matter of fact, somewhat higher, for the opening of this crater was higher than the surface of the moon. But now I was falling *toward* the sun, and the sun was aiding as well as accelerating my flight; for I moved constantly nearer to it.

"For this reason at the end of 48 minutes I did not strike the eastern end of the crater. Instead I whizzed right past the eastern wall, almost brushing it, and continued to rise up into the air about 100 feet before my speed was spent. I promptly prepared myself to plunge down into the crater again. Indeed, before I realized it I had begun to fall down once more when the unexpected happened.

"I suddenly felt a rope encircling my body, and before I had time to think I was jerked sideways, and in another second I had fallen on a heap of sand and looked with astonishment into Professor Flitternix's eyes, who stood over me grinning sheepishly!

"This is what happened: Flitternix had, of course, seen me fall into the crater, and as he had rushed to the edge he had seen how I dropped down at lightning speed. Looking closer, he also noticed what I saw, namely, that the crater went right through the entire diameter of the moon, for he could see the stars shining through from the other end. He was loath to believe that the fall would kill me, and, as a scientist of note, he calculated exactly in advance what was likely to happen to me. He reflected that it would take me some two hours to make the round trip, as he knew that I could not possibly stay at the other side of the moon. He reasoned, correctly, that in case I was not killed I would come swinging through the crater in due time. Unperturbed as he is by such mere details, he went to the 'Interstellar' and had his lunch. Within two hours he returned to the crater, armed with a telescope and a long rope. It did not take him long to locate me down in the abyss by means of his glass, for I was rapidly coming to the surface then. Attaching one end of the rope to a near-by rock, he fashioned a sliding noose on the other side and waited.

"Now it must be said to the credit of Flitternix that in his younger days he had lived in the West on a ranch, and there had become an expert in the science of lassoing. He boasted that once he lassoed a common sparrow by its left hind leg, but this I believe to be somewhat exaggerated. Be that as it may, when I finally emerged to the surface, a living piece of lava ejected out of an extinct crater, Flitternix had but little trouble in lassoing me as I came whizzing up. Whereupon I thanked him and asked him if lunch was ready, for the trip had given me quite an appetite, as you may well imagine. Luncheon over, we decided right then and there to quit the moon, for Flitternix as well as myself were of the opinion that there was little further to be

*†An object weighing 1 lb. on Earth weighs 0.167 lb. on the Moon.†

*†The speed of a falling body at the surface of the earth after the first second is 16 1-12 feet. In 6 seconds a stone would have traveled but 579.†

The Gravitation Nullifier

Ned Cawthorne, Millionaire, "Floats" a New Issue, but Not of Bonds

By George Frederic Stratton

THE gigantic mogul, No. 73, had been held on a siding on the Santa Fe Railroad waiting for three troop trains to pass on their rush to the Rio Grande. Behind her were 40 empties which she was hauling back to be reloaded with munitions and supplies and again to be rushed to the front.

Blakely, the engineer, who had been 19 hours on the run and saw no relief until he reached Los Lunas, was doggedly morose, for his orders were coming from dapper second lieutenants or curt, brusque majors, instead of through smiling station agents with their crisp telegrams. At last he got his signal and viciously pulled his throttle. There was a furious rush and whir of the 12-coupled drivers but no headway.

He instinctively shut off steam, turned on the sand and again slowly and cautiously opened the throttle with the same result—a whirl of the drivers as if they were the wheels of a child's wagon, spinning in the air.

"Grease?" grunted the fireman.

"There'll be a grease-spot if I catch any blamed fools playin' tricks 'round here!" howled Blakely as he sprang from the cab.

But he found nothing wrong. The rails were dry and in perfect condition; and with a lowering puzzled look he climbed back into the cab, threw over the reversing lever and opened the throttle. There was not the slightest impulse backward or forward.

The sharp exhaust cut out the explosion of picturesque idiom and expletive from Blakely. Then he yelled to the conductor who had come forward: "Cut her loose, Hank!"

The mogul was uncoupled and again the engineer gave her steam and his puzzle became a miracle. The great locomotive started forward with a plunge which threw the fireman back on the coal; the forward trucks sprang clear of the rails and a sharp gust of wind sweeping down the arroya lifted the huge machine into the air and floated it across the main track. Then it settled down in the sagebrush so gently as not to displace one chunk of coal.

Blakely slumped back on his seat, aghast, and the tan on his corrugated cheeks and forehead faded off to a sickly ashen gray. The fireman sprang from the cab, his hair standing on end, but instead of his feet reaching the ground the breeze caught him and wafted him along as though he was thistle down. Fifty yards away he drifted against the telegraph wires and clung to them convulsively. Grouped between him and the engine were the train crew and station helpers, staring in bewildered terror, and a few yards behind them stood a man, dressed in gray, waving what looked like a pocket searchlight, in signals to a biplane, far overhead.

A cavalry lieutenant with a squad of troops galloped round the station and down the track, halting as they reached the man in gray.

"What does this mean, sir? What aeroplane is that, and why are you signaling? Who are you?"

"My name is Cawthorne," smiled the other. "I'm interested in a new device for suspending gravitation, and that biplane is operating it." He turned to the fireman in the wires and shouted: "Drop off at the first lull of the wind. You'll settle down, all right."

The lieutenant spurred close to him. "I suppose you know that the road is under martial law and that you're interfering with its operation. You're under arrest, sir!"

". . . . Thousands of Men Were Wriggling in the Air, Mixed Up with Machine Guns, Mortars and Small Arms."

"Certainly," grinned Cawthorne. "Now, perhaps you'll allow me to put that locomotive again into commission."

He stepped over to the great engine, followed by the officer and his squad, and placing one hand under the cowcatcher lifted the entire front of the locomotive clear of the sagebrush.

"Gravity entirely gone!" he laughed. "Call on two or three of those men to help and we'll put this back on the track in a moment. Then we'll restore its weight and it can go ahead."

The officer scowled and hesitated. Then he ordered four troopers to dismount and help. Two minutes later they had carried it over to the head of the train. As they did so, Cawthorne again signaled the biplane. Then he stepped to the cowcatcher and heaved on it.

"Weight's all back, lieutenant! Now I'm at your service."

Two hours afterwards Cawthorne, escorted by the cavalry squad, arrived at the headquarters of the Fifth Brigade and was immediately taken before General Illington. That grizzly old warrior scrutinized him keenly; then growled:

"You are Mr. Cawthorne—Edward Cawthorne, I am informed."

Ned bowed. The general smiled grimly and continued:

"The man who devised those submarines that have been putting the Jap dreadnaughts to sleep?"

"I am the man who financed them, general. The deviser is a man named Wheaton, of Providence."

"Very effective, sir; whoever did it. But ——," and a scowl darkened his rugged face, "that is no excuse for experimenting on our battle line. Nothing can be an excuse for that, sir!"

"It was not experiment, general; but demonstration. Shall I explain?"

"I will listen to you, sir, but I warn you that no explanation can relieve you of the consequences of your action. You delayed that freight train for nearly ten minutes—a very serious matter at this time! Orderly! Request Captain Berger to come here."

In a few moments the artillery captain appeared. The general muttered:

"Mr. Cawthorne proposes to explain the method by which he floated that locomotive off the tracks. Be seated, gentlemen!"

"Four years ago," Cawthorne related, "a Mr. Farrow showed clearly that the law of gravitation is influenced by the Hertzian waves, and that they, in turn, could be influenced by electricity. I need not take up time to go into the technicalities of it all, but experimentation, right to the limit, has resulted in an apparatus—a condensing generator—which if so handled as to throw an electric zone around anything that has weight, will eliminate that weight, or more properly, will nullify the gravitation. That locomotive was treated from our gyroplane nearly 5,000 feet above it!"

The captain gasped: "Do you mean, Mr. Cawthorne, that it was done without any communication with the earth—that there was no receiving antennae?"

Cawthorne grinned, slipped his hand in his pocket and drew out a few metal balls, as small as buckshot. He handed a couple to the general and the others to the captain.

"Those are the antennae. Simply solid metal balls! I don't care to tell the composition, just now; but they're perfectly harmless. A bushel of them was carried in the gyroplane and a few handfuls thrown down around the locomotive. Then, when the condensing generator was put into action the current found those antennae and the gravitation-suppression instantly occurred."

"Good heavens!" ejaculated the general. "It's beyond the realms of possibility, Mr Cawthorne!"

"Edison says that the limits of the possibilities of science are not yet in sight. What we have done seems impossible because it has never been demonstrated. But, your officer has seen, and has reported to you about the possibility."

"And the influence—or whatever it is—extends only to the radius covered by those balls?" broke in the captain.

"Much further than that, captain. On exhaustive experiments at my country home, conducted very secretly, we found that the influence—that's a good term—extends for fully half a mile on each side of any cluster of balls; although the intensity of the action is at its fullest among those balls. The suppression of gravitation becomes less as the distance increases."

"And yet the altitude of your gyroplane makes no difference?" demanded the general.

"We have worked up to 6,000 feet without finding any difference in the conditions or results."

The captain settled back in his chair and gazed at Cawthorne in blank astonishment, his arms hanging limply on each side of him. The general twisted one end of his gray mustache into his mouth and chewed it meditatively. Presently he growled:

"Why have you not put the war authorities in touch with this, instead of daring to come right onto the field and make a demonstration without even consulting me?"

Cawthorne leaned forward, his brows furrowed deeply and his lips pressed tightly together:

"Two years ago, general, the war authorities were shown this apparatus and they shrugged their shoulders and turned it down. If we had gone to them now with the perfected machine they'd have red-taped it until those Japo-Chinee devils had reached Washington, and then they'd have appointed an investigation committee, with an unlimited period of time for the investigation and tests. War authorities are not field officers, general!"

"That will do, sir! I can listen to no criticisms on the Government." But a twinkle in the stern old eyes softened the harshness of his tones.

"Your gyroplane is here, I suppose you know?"

Cawthorne grinned: "Yes! As soon as I heard where I was to be brought I signaled Kilroth, my assistant, to sail in here and descend. I suppose he's under arrest, too?"

The general smiled grimly but ignored the question.

"How did you expect to follow this up, Mr. Cawthorne?"

"First, by doing just what has happened—getting an interview with you. Next, by sailing over the river and—with your permission—floating all of that Chinee-Japo-Mexican aggregation into the air. How's that?"

The general glanced at the captain, his lips twitching. The next moment both burst into a roar of laughter. As it subsided, the general's hand shot out and grasped Ned's. "We can use you, sir! We'll have to, to save ourselves. I could spare 25 or 30 pounds very willingly, but the rest of my weight I want.

"But, under the regulations of war you'll have to come under my command. I'll appoint you a captain of aviation. Will that do?"

Cawthorne exclaimed bitterly: "It has been my greatest ambition to hold a commission in this war, general; but I have a cork leg—lost the other at polo. Does that disqualify me?"

"Perhaps," smiled the general. "But the aviation service is hardly down to fine restrictions, yet. We'll overlook the cork. What men do you carry in that aeroplane?"

"Two. Kilroth, one of the brainiest mechanics I ever knew, and Littleby, the —er—chauffeur, but there's room for two others."

The general nodded exultantly. "Captain Berger, you are detailed to accompany Mr.—er—Captain Cawthorne. Your rank, as an artillery officer, is above his, but you will act together. Now, I am going to call a council of war which you will both attend. We will then decide on your future movements."

"And in the meantime," laughed Cawthorne, "where am I to report? I am under arrest, you know."

Another laugh broke from the general. "You are on parole now, captain. Orderly! Report at the guard house that Mr. Kilroth and the pilot of that gyroplane are to be immediately released!"

As the orderly left, Cawthorne saluted and said:

"There are on the track at Denver three sealed freight cars consigned to me. They contain three more gyroplanes and a number of gravitation nullifiers. I didn't dare bring them any further for fear of —er—arrest; but they are now under your orders, general!"

"Good heavens! Three more of those machines all ready! Have them forwarded at once, captain! No! I'd better make the order—special run, too! We need all the reinforcements we can summon just now!"

* * *

Four thousand feet in the air the two captains, Cawthorne and Berger, were cruising over the trenches of the mixed brown and yellow men. Around them were a score of United States aeroplanes guarding the G. N. 1 against attacks by Japo-Chinee airships.

The world just below was sparkling with angry flashes of flame preceding the rattle of machine guns and the explosion of shrapnel. The enemy had brought up no heavy guns, but from the American lines across the river came the terrific crash of field siege cannon. As far as Cawthorne could see on both sides of the Rio Grande were gusts of smoke; sometimes spasmodic; sometimes continuous clouds, for the entire line was in action.

Berger was watching the *seleniumphyscho* plate on which, projected by the *J-ray* tube at headquarters, eight miles away, came their orders. Kilroth and Cawthorne were sifting handfuls of the globular antennae—Kilroth called them "attractors"—down onto the line of trenches beneath. Suddenly Berger exclaimed to the pilot:

"Turn back, Everoth! Follow the same line! Now, Captain Cawthorne, put the generator-condenser into action!"

Cawthorne threw the switch and all gazed down. One aeroplane immediately below them was evidently deprived at once of its weight for its pilot lost control and it darted in a complete vertical revolution and then rushed far into the south.

"Must have caught a few of our attractors," grunted Kilroth. "Look below!"

Beneath them was as much confusion as if a tremendous explosion had occurred. Thousands of men were wriggling in the air, mixed up with machine guns, mortars and small arms. Everoth had slowed his motors down to 20 miles an

hour and in 15 minutes the generator condenser had passed over the five-mile line of trenches and utterly demoralized the enemy.

Firing ceased instantly and as the smoke swept away the fighters in the G.N.1 had a clear view as they turned and again sailed over the line. For a half mile ahead and behind them and to each side the enemy and its equipment were in the air, and as a stiff breeze was blowing into the north, thousands of those brown and yellow men and thousands of small arms and big guns were drifting like feathers towards the river.

As the gyroplane passed along and its zone of influence left those aerial enemies, their weight came back as suddenly as it had been nullified, and they dropped onto the plain or into the river. Firing from the American side had ceased and Berger yelled:

"Look Cawthorne! Our men are rushing down the pontoons. They'll have a bridge across in an hour! All we've got to do is to keep these fellows floating and dropping until our troops get across!"

They glided down within 200 feet of the surface. The enemy's aeroplanes had darted away, for as they came within the influence of the nullifier their control became alarmingly erratic. The American airships, previously warned, were prepared and followed the enemy in fierce attack.

Suddenly there was a shrill yell from the pilot, a dark shadow and a crash. One of the enemy's biplanes, recklessly driven or out of control, had rushed into the path of the G.N.1. There was no weight to either of the fliers, but the initial strength of structure was there, and the speed, and in a moment—the nullifier being crumpled out of action—both planes were toppling to the ground. All but Everoth, who came down on rocks and broke both legs, landed in one of the trenches on top of a party of quivering Japs who had crawled back there after the first attack of the mysterious influence. But for the fact that in their aerial flutterings their rifles and even their revolvers had wafted away from them, Cawthorne and his party would have met instant death. But they scrambled out and drawing their own revolvers, clustered about the wrecked gyroplane.

Captain Berger glanced around him. On every side sprawled men, clutching rocks, sagebrush, each other or parts of field guns; anything which, in their abject terror, might keep the weird, mysterious unknown from fluttering them again off their feet. Many of them were dead from plunges from great heights when their weight was restored. Many others were crippled in limbs or ribs. Others were crushed under machine guns or howitzers which had dropped on them.

Down at the extreme right of the line—a position which had been held by Cabellero's Mexicans—Berger saw a large body of them rushing in frantic disorder back across the great plain to timber far in the rear. At another point nearer to him was a Jap officer gesticulating to his men in an effort to reorganize them, but not a man but himself was standing up.

"Here's a rescue, Berger!" shouted Cawthorne, as a big aeroplane glided to the ground close by, and he saw the khaki uniforms.

Instantly a lieutenant sprang out and ran over to them.

"We've room for your party, Captain Cawthorne. You can do nothing more here, I suppose," with a glance at the smashed gyroplane.

Cawthorne looked at Berger, who nodded, and then said:

"One of our men is injured. Is it possible to carry him out of this?"

"Here's another aero coming," replied the lieutenant. "Hi! What's this mean!"

A hundred rods to one side a number of armed Japs were rushing towards them. Cawthorne's party drew close together, revolvers in hand.

"Hold your fire 'til they're within a hundred feet!" commanded Berger, but the next moment Kilroth gave a fearful shriek, sprang four feet in the air, his arms waving wildly, and as he came down, he clutched at the wheel of a gun and clung to it, still howling.

The effect on the Japs was instantaneous and astoundingly effective. Everyone of them was groveling on his belly, clutching at brush, at rocks, at the hair or arms of his fellows, at anything for an anchorage to his dear old Mother Earth.

Kilroth doubled up in a paroxism of laughter, the contagion of which spread to the others.

"Pick up that wounded man!" shouted a voice, and they lifted him into the frame of the second aeroplane. Another instant they were all again in the air, sailing at full speed towards headquarters, while the Japanese officer was leaping among his prostrate men, striking them with the flat of his sword and using language which was perhaps appealing eloquence, but was certainly decorated with an unlimited assortment of profane trimmings.

"Marvelous! marvelous!" muttered General Illington as he heard their report. "Two hundred thousand of the enemy routed, and not one of your men lost!"

"One man injured!" grinned Cawthorne, "and we brought him out."

"The loss of the gyroplane is serious," muttered the general. "The enemy may rally before we get our bridge across; it will take fully an hour, yet; even if the engineers are not attacked by shell."

Captain saluted: "I think, general, that there isn't a gun over there in condition to go into action without repairs or adjustments."

"Have the other gyroplanes left Denver yet?" asked Cawthorne.

The general growled: "A report came in just before you arrived that the train had reached Valencio. But it adds that the line is terribly congested and that the train cannot reach here for 40 or 50 hours—perhaps longer!"

"Valencio!" muttered Cawthorne, "that's 400 miles. An aeroplane could make it in five hours, or less; we could assemble a machine in two hours and bring it here in another five. Twelve or 15 hours at the most, general!"

"Do it!" exclaimed the general. "I'll order those cars sidetracked at—er—Captain Berger, find out what station that train will reach five hours hence, and dispatch orders to drop those three cars there!" Then turning to Cawthorne: "The enemy has heavy reinforcements coming up, within a hundred and fifty miles of the river; and you'd be back in time to meet them. Take all the men you need and return with the first machine you can get together!"

Then he turned with a chuckling grin to Kilroth.

"You, my nullifier impersonator, can, I suppose, assemble the other machines and bring them to the front without delay?"

Kilroth grinned and bowed. Ten minutes later the party, with four skilled mechanics, were sailing north.

* * *

Coming northeast from Guaymas Bay, in the Gulf of California, was the main army of the Japo-Chinee-Mexican alliance. Almost in sight of each other train sections were crawling along the railroad, bringing up heavy field guns, aeroplanes, munitions, supplies and men. On the trails and plains mounted Mexicans of Cabellero's and Valejo's commands were advancing, devastating every ranch, village and town on the 10-mile wide trail.

The head of this army had reached Guadeloupe, 40 miles from the Rio Grande, and had encamped there waiting for more forces to come up; but when the amazing news arrived of the mysterious disaster at the front, they were again put on the march. Presently fugitives from the river straggled in, amazing and terrifying the new men with stories of their flotations.

A great group of aeroplanes appeared, three or four thousand feet above, for excepting a few held back for scouting purposes, every airship in Illington's division was escorting the G.N.2. Hovering about them at respectful distances were a few of the Japo-Chinee airships, and occasional flashes from guns showed spasmodic attempts at interference.

Presently there dropped on the advancing troops small pellets of metal which, coming from so great a height, caused severe wounds on the few men they happened to hit. Then one gyroplane—the G. N 2—darted below the others and glided directly over the column of troops beneath.

Again were the astounding conditions and demoralization at the Rio Grande repeated; but as there was not the slightest breeze the effects were not quite so evident to Cawthorne's party. Men lifting their feet to the march step were unable to replace them with any accuracy and would stagger or drift against each other in utter helplessness. Horses hauling heavy guns and baggage wagons suddenly plunged ahead as all weight behind vanished and then reared and sought in vain for secure footing. In an instant, as the gyroplane glided slowly over them, all order, all discipline and all courage disappeared. Men fluttered along the ground—sometimes head down, sometimes half a dozen clutch-

(*Continued on page* 300.)

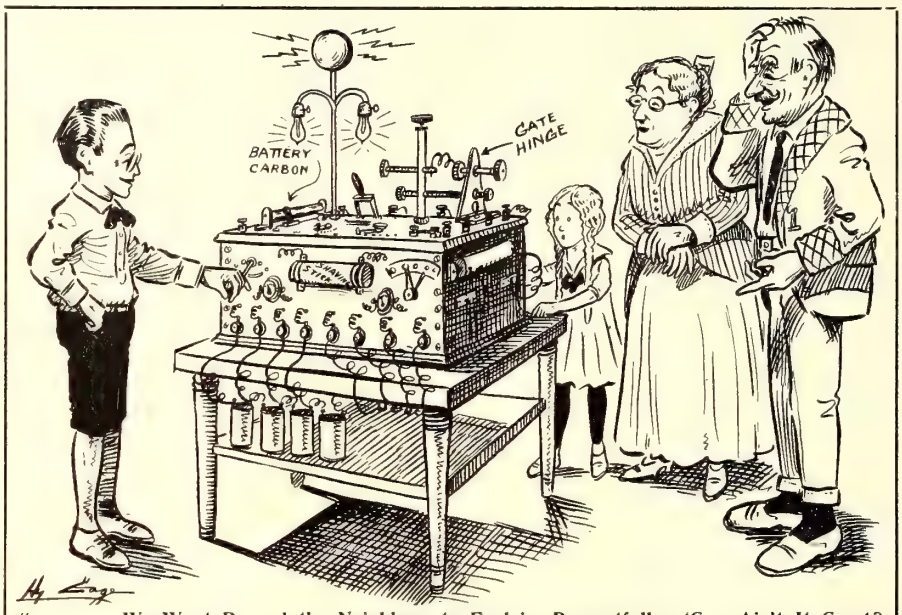
YOU have read, of course, Mr. Stratton's interesting story "Omegon," last month. Here's the continuation: This story is as startling as it is original; moreover it is exceedingly timely and it may sound far more impossible than it really is, for Professor Thomas Jefferson Jackson See, of the Naval Observatory at Mare Island, Cal., has just announced one of the most important and momentous discoveries of the age. He claims that gravity is but another electrical phenomenon caused by electrical currents circulating about atoms of matter. If this is really so—and we have no reason to doubt the new theory—then Mr. Stratton's story is not only probable, but highly possible.

You must read this tale by all means.

Conserving Uncle George

By Thomas Reed

YOU know that gentleman by the name of Sloyd? He was the apostle of Care and Pains. If you are making a joint, he says fuss over it as though all the joiners of Joinville were watching you with their eyes bulging out. And don't you dare to fudge it up.



The article you are making is not so important. You simply think up something to make that will have to have a joint on it. Say you decide on a nice knife-tray for mother. Mother would rather have a new set of knives and could keep them any old place; but father missed it on Amalgamated Shoestring Common and can't see the knives just now. Sorry. All the same mother pats you on the shoulder and says what a dear, thoughtful boy you are, and the hired girl turns the tray over and uses it to set the garbage pail on. And so it goes.

Sloyd may be all right for certain natures—there's room for lots of things in the world—but the Experimental Bug thinks life is too short for his philosophy. If I confess something don't you tell Gernsback or he'd fire me out of the *E. E.* with a splash, mother's overboard; but I'd rather see an odd contraption rigged up out of a tomato can and three umbrella wires than the most perfect skewangular joint in the world.

Sloyd begins at the back end. You and I start by wanting something and wanting it bad, and then we go to work and make it with what tools and materials we've got. When it's done it may look like a chance grab from the dump, but what of that if it works?

Then if our crude rinktum succeeds, we begin all over again and rebuild it in worthy form—doll it up with a mahogany base and plenty of binding-posts. Even a few superfluous switches and milled nuts are not amiss just to give it tone. Oh I'm wise, I've been there. We want pa and the neighbors to exclaim respectfully, "Gee, ain't it great? what's it for?" instead of smiling scornfully as they recognize the gate-hinge, the dry-battery carbon and the shaving-stick box.

In the chronic state of a boy's exchequer it's a tough choice between tools and materials, because every dollar spent for one means one dollar less for the other. Well, what'll we do about it? Conserve your resources, I say.

". . . . . We Want Pa and the Neighbors to Exclaim Respectfully, 'Gee, Ain't It Great? What's It For?'"

"What's that?" say you, "conserve 'em? They're so small it's as much as I can do to find 'em, let alone that con—con—that phoney word you used." "Well, listen," says I, "part of your resources is Uncle George, isn't it? Don't he generally come across about Christmas time or the birthday? Sure he does. Then he's a resource and you want to conserve him."

Now it's this way: Don't tap Uncle George for materials, but let him buy the tools. The little roll of that silk-covered wire that you want so much wouldn't appeal to him. It disappears and he thinks you're extravagant, and extravagance is bad for you. What he wants to give you is something large and shiny—something you can pick up any time and say with tears of gratitude in your eyes, "Uncle George gave me that."

Well, humor him—that's the way we old fellows get to be so awful rich. Pretty soon Uncle George will begin testing out the ground in the guise of advance agent of S. Claus & Co., Ltd. Now don't let him, in his ignorance, blow you to one of those so-called tool-chests at which a pound of cheese would laugh. What do you want of a young tack-hammer, a chalkline, plumb-bob and a square that isn't square? No, sir, hand it to him straight about the drill and the center-punch and the hack-saw. Head him off from one of those things you can imitate a suspension bridge or a flying-machine with. If he commences to talk in two figures like a sport, you can suggest that he who passes along a good lathe would surely avoid the appearance of a piker.

Here's a list of tools you want—tools to use, not to form a museum with. Paste it in Uncle George's hat or on his eyebrow, and you will never regret it, though he may. I don't include the necessary hammer, saw, plane, etc., as I assume you have pinched father's!

Hand drill, $1.25; hacksaw, 50c.; hand beading tool, $1; center punch, 10c.; metal shears, 50c.; pliers, 25c.; iron rabbit-plane, $1; marking gauge, 25c.; iron vise, 3-in. jaw, $1.50; miter-box, $4.50; ratchet bit-stock, $1; countersink, 10c.; hand emery-wheel, $1.29; compass saw, 25c.; oilstone, 25c.; lathe, $40; bench vise screw (make your own jaws), 50c.; files, flat and half round, 25c. each; twist drills, 1/16 to 3/16 by 64ths, about $1; wood bits, 1/4, 3/8 and 1/2 in., 25c. each; expansion bit, 1/2 to 1 1/2 in., 75c.; 8/32 tap and die, with die stock, $1.50; tool handle with enclosed awl points, etc., 25 to 75c.

Hits any mark from a tightwad to a joy-rider, eh, Bugs?

PROF. SEE CLAIMS TO KNOW CAUSE OF GRAVITATION.

Dr. Howard D. Minchin, of the University of Rochester, will inquire into the announcement of Prof. Thomas Jefferson Jackson See, one of the best-known astronomers and mathematicians in the United States and at present in charge of the Naval Observatory at Mare Island, Cal., that he has discovered the cause of gravitation. Students in science are greatly interested in the announcement coming from a man of such standing. Dr. Minchin said he could not intelligently comment on the discovery until he had investigated.

Professor See contends that gravitation is an electrical phenomenon which is caused by elementary electrical currents circulating about atoms of matter. The theory of Professor See is an extension and elaboration of physical laws first demonstrated by the French physicist, Ampere, 95 years ago. Ampere, whose name has been taken to denote the unit of electrical current, showed that two parallel currents of electricity flowing in the same direction attract each other, but repel when flowing in opposite directions.

The more atomic electric currents around one body of matter flowing in the same direction as the atomic currents in an adjacent body the more the two bodies will be attracted, Professor See contends, and this mutual attraction is nothing more nor less than gravity.

Gravitation, Professor See contends, does not act instantly across space, but is transmitted with the velocity of light. Thus it would come from the sun to the earth in eight minutes.

Professor See's treatise on his discovery is in the possession of the Royal Society of London. It was to this society that Sir Isaac Newton announced his laws of gravitation in 1685. The society has not yet passed upon the theory.

U. S. NAVAL RADIO SCHEMES PROGRESS.

The naval radio construction program of the Government has gone far enough to warrant the statement that it is to be carried forward to completion without exceeding the $1,500,000 limit of cost fixed by Congress. The system when in operation, it will be recalled, is to circle the globe, giving the American Government at Washington, D. C., direct control of its battleships, no matter in what part of the world they may be located.

The fund has been used in the construction and equipment of the naval radio station on the Canal Zone, which is now in operation; and is being used for the stations at San Diego and Honolulu, where work has begun; at Cavite, where arrangements for construction are under way, and at Guam, where the project is in the initial stage.

Can Electricity Transfer Thought Waves?

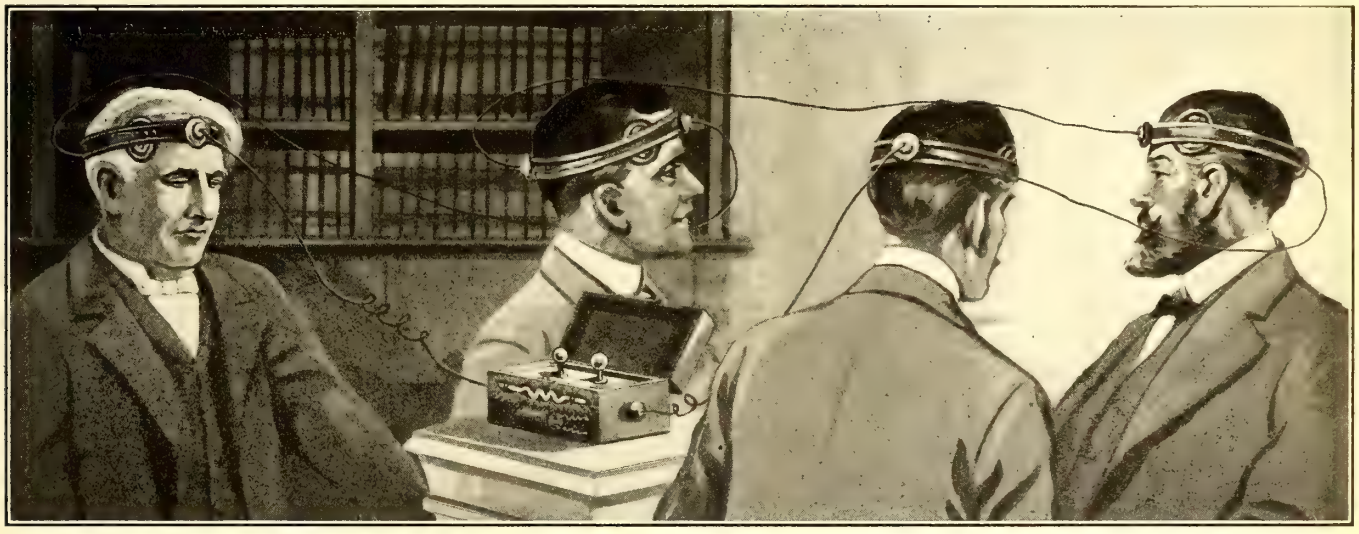
WHETHER electricity can or cannot transfer thought waves from one human brain to another is a much mooted question which has for some time occupied the minds of many of the foremost scientists in the old and new worlds. Among some of the more well-known and brilliant men who have seriously considered this matter there may be mentioned Thomas A. Edison, Sir Oliver Lodge and Prof. Alexander Graham Bell.

This whole subject revolves in a way about the science of psychic phenomena, it may be said, and this branch of little understood science considers as an absolute fact that "thoughts can be transferred from one mind to another," and in many cases workers in this branch of *science* (shall we call it science?) even claim to communicate with the departed spirits of deceased persons.

While most of us, in view of the present great intellectual activities and enlightenment of the day, are prone to scoff at all such theories and alleged demonstrations of a new art, it seemingly behooves us to think over the matter more than once, when such great scientific investigators as Bell, Edison and Lodge will condescend to look into such things seriously.

At a recent meeting of the American Institute of Electrical Engineers at New York City, where Dr. Bell, inventor of the telephone, was presented with the Edison medal "For Meritorious Achievement in Electrical Science," he, in response to the presentation address accompanying the gift of the medal, spoke as follows:

"What will come next? We now have electric light, electric power, electric speech and a swarm of electric appliances that have come into use during recent years. All of our knowledge of the external universe is derived from our senses, and science has brought electricity to the service of practically all of our senses. Are you going on? The possibilities of further development are inconceivable."



"Men can do nearly everything else by electricity already, and I can imagine them with coils of wire about their heads coming together for communication of thought by induction."

The audience of 1,000 electrical engineers and their guests showed no sign of being incredulous, even of this suggested possibility of electrical development. However, Dr. Bell added:

"But that is for you to make possible," with emphasis on the "you," and when the laughter had subsided he continued: "I have been struck by the fact that nearly all of the recent steps have had to do with vibrations. Suppose you have the power to make an iron rod vibrate with any desired frequency in a dark room. At first, when vibrating slowly, its movement will be indicated by only one sense, that of *touch*. Soon, as the vibrations increase, a low *sound* will emanate from it, and it will appeal to *two* senses. At about 32,000 vibrations to the second the sound will be loud and shrill, but at 40,000 vibrations it will be silent, and its movement will not be indicated by touch. Its movement will be indicated by no ordinary human sense. At 100,000, up to about 1,500,000 vibrations per second, we have no sense that can appreciate any effect. After that stage its movement is indicated first by the sense of *temperature*, and then, when the rod becomes red hot, by the sense of *sight*. At 3,000,000 it sheds violet light."

"Now the thought has occurred to me that there must be a great deal to be learned about the effect of those vibrations in the great gap where the ordinary human senses are unable to *hear, see* or *feel the movement*. The power to send wireless messages by etheric vibrations lies in that gap, but the gap is so great that it seems there must be more. You must make machines practically to supply new senses, as the wireless instruments do. Can it be said, when you think of that great gap, that there is no field in the further development of electrical science for you?"

The illustration herewith gives an idea of how the inductance coils proposed by Dr. Bell would appear on the head for the transmission and reception of thought waves from the human brains.

Will the Day Come When Even Our "Thoughts" Can Be Transmitted From One Brain to Another, Electrically?

Sir Oliver Lodge, in dealing with the development of news intelligence transmission has declared that it is not unreasonable to say we will eventually become so developed that one man may call another by name, seeking to find him among the millions of the world's population, and if that man answereth not then he must be no more in the flesh. This, indeed, seems to be one of the wonderful objectives toward which modern scientific investigation is directed.

Dr. Alexander Graham Bell has already experimented on the transmission of thought over long distances by means of electrical induction. The inventor of the telephone and his assistant, Prof. Ellis, capped their heads with improvised induction coils, but the only result of the brief first experiment—revealed by chance two years later—was that, while there was no transmission of thought, the sensation of nausea that afflicted Ellis at the time was communicated to Dr. Bell, a fact that he readily recalled when, in discussing the test after the lapse of time, the professor said he did not consider it a fair trial because he had a sick headache and a feeling of nausea. Dr. Bell thinks that it may be that various sensations can thus be more readily communicated than thought, and he expects at some future time to begin a more thorough experimentation.

Thomas A. Edison, the wizard of all inventors and probably the foremost American scientist, has been much impressed by some of this so-called *mental telepathic* or *thought wave* transmission, and particularly by one expert by the name of Mr. Bert Reese. Mr. Edison made a number of different rigid tests in connection with Mr. Reese, and also he made several experiments between the expert and employes at the Edison plant. Mr. Edison says of this matter: "Then I asked him to let me try. In my case I went into another building and wrote down the words 'Is there anything better than nickel hydroxide for an alkaline storage battery?'

"At that time I was experimenting with my new storage battery and felt somewhat dubious about being on the right track. In the meantime as I folded the slip of paper containing the above words in writing I filled my mind with a different problem and kept working on its solution so that Reese could not by 'mind-reading' decipher what I had written on the slip of paper, and returned to the room where I had left Reese. At the moment I entered the room he said: 'No there is nothing better than nickel hydroxide for an alkaline storage battery.'

"He had therefore read my question accurately, and to this day I am satisfied that there is nothing better than nickel hydroxide for that particular purpose.

"About two years afterward the boy from the gate-house of my laboratory came in and announced that Reese was in the gate-house and wanted to see me. I took out my pencil and wrote in microscopic letters the word 'keno.' I folded the paper, put it in my pocket and then told the boy to bring Reese in. I greeted him and at once said: 'Reese, I have a slip of paper

CHURCH SERVICE BY TELEPHONE.

By E. O. Catford.

In Guernsey, England, if a Sunday happens to be disturbed by the elements, the populace can remain at home by their comfortable hearth and listen to the sermon, the organ and choir instead of tramping through the rain or snow, as the case may be, and then arriving at the church in so irritable and distressed a condition that they can hardly and whole-heartedly participate in the church service.

This is accomplished by having the telephone exchange connect you to the church by a switch. The charge for this service is 10 cents, but public officials, such as police, firemen, militia and others, who are kept from church services by their duties, are given the privilege free of charge.

At Platte Fougère Light-house Station (Guernsey), where these photos were taken, frequently as many as eight persons sit around the table on a Sunday evening, listening to the minister's sermon five miles away.

Two Views of Telephone Installation on Island of Guernsey, England, Whereby Soldiers and Others Can Hear Church Services Five Miles Away in Any Kind of Weather at Cost of 10 Cents. Microphone on Pulpit is Marked at Left.

TESLA SUES MARCONI FOR WIRELESS CONTROL.

Nikola Tesla has appealed to the law to declare that he and not William Marconi is the inventor of wireless telegraphy. Many millions in money and world-wide control of the commercial use of the wireless transmission of energy are involved in the struggle.

The suit has been brought in the United States District Court in the name of the Nikola Tesla Co., of which the Serbian inventor is the president, and to which he has transferred all of his fundamental patent rights in wireless telegraphy. The defendant in the action is the Marconi Wireless Telegraph Co. of America.

Mr. Tesla announced recently in connection with the suit that he has just been granted a patent by the United States Government which will supersede and revolutionize all present forms and applications of wireless telegraphy and will enable him and the financiers who are associated with him to obtain and keep a hold on commercial wireless telegraphy, no matter what may be the outcome of the litigation he has begun against the Marconi interests.

"My earlier experiments in Colorado in 1899," he said, "demonstrated that I was on the right track, and with a transmitter of my invention of not more than 30 inches in diameter I succeeded in concentrating and applying an amount of electrical energy twice as strong as is contained in an ordinary stroke of lightning.

"Since then I have pursued my experiments with that one point in view, namely, the discovery of a way of concentrating and absolutely controlling electrical energy. This result has been attained under the workings of the apparatus for which the Government granted me a patent last December.

"I now claim that I can confine any amount of electrical energy, and that, too, without the use of insulation. The Marconi and other existing systems of wireless telegraphy require that there shall be insulation in connection with the transmitter. I can now send a wireless current entirely across the ocean.

"In transmitting a Marconi wireless current, for example, not more than 20 or 30 horsepower of energy is required; with my new apparatus I can concentrate and direct 5,000 horsepower of electrical energy.

"With this tremendous energy thus concentrated and controlled I can telephone by wireless across the ocean. I can use the apparatus, also, for sending a blaze of light over great distances."

Mr. Tesla in the complaint alleges that he is the inventor of a system of transmission of electrical energy and of apparatus arranged for that method and system, for which he received a patent, numbered 645,576, applied for on Sept. 2, 1897, and issued March 20, 1900, and for which he also received a patent, numbered 649,621, applied for at the same time as the other, and issued by the commissioner on May 15, 1900.

Marconi's application for a patent on wireless telegraphy, the complaint asserts, was filed on Nov. 10, 1900, and was not granted and issued until June 28, 1904, being numbered 763,772.

The Tesla company asks the court to declare the Marconi wireless telegraph patent null and void, claiming that the Marconi patent covers the inventions and combinations of apparatus described and claimed in the Tesla patents.

The Marconi company has put in an answer denying any infringement.

The Tesla company also has begun a suit against the Marconi company for alleged infringement of the Tesla patents.

[*Ed. Note.—Tesla's patents and wireless transmission of energy are covered in "Wireless Telegraphy" by Sewall, procurable from our Book Department at* $2.15 *prepaid.*]

CAN ELECTRICITY TRANSFER THOUGHT WAVES?

(*Continued from page* 253.)

in my pocket, what is on it?' Without a moment's hesitation he said 'keno.'"

Mr. H. Gernsback, who has studied considerably such matters as mental telepathy and also such matters as "thought transmission" in so far as the matter can be studied at this time, has made a suggestion which may be mentioned as worthy of trial in this field. This suggestion embodies the use of a set of one or more sensitive Thermo-couples, which, as we know, produce an electric current whenever they are heated. It has been found that invariably whenever the brain is concentrated on some problem, or thought, that heat is produced in such a way that it will cause the forehead of a person to perspire, even though slightly. Now if this Thermo-couple arrangement is placed against the forehead there is a possibility that waves might be picked up and transmitted over a wire to a proper receiving apparatus or instrument attached to the head of a second person.

A theory promulgated by Mr. H. W. Secor takes for its basis a somewhat different phenomena. This particular action is nothing more nor less than the *Aurora,* which we know exists for quite an appreciable distance about the human body. Some time ago a well-known English scientist and investigator made it possible *to view* these vari-colored *aurorae* surrounding the human body by utilizing specially devised screens, and when looking through these screens the ever-changing aurora about the body could be very clearly observed. Moreover, and in line with Mr. Secor's theory, these aurorae are of different colors or hues for different conditions of the mind or brain in the person under observation. They are red, or reddish yellow, when the person is in great anger, and thus they change through various colors for different emotions. If the inductance coils of Dr. Bell, and proposed by him to be strapped around the head, will work at all, it seems very likely that they would act by means of these aurorae discharge from the body and which quite possibly is electrical in its nature. If this is so then a simple coil at both transmitter and receiver end of the line should suffice, as the variation in the electrical *aurorae* setup about the body and controlled by the brain would then induce corresponding ever-changing currents in the first coil to be transmitted over the line to the second coil. This coil could then, in virtue of the fluctuating currents passing through it from the line, influence the *auroral field* about the body of the second person on whose head the coil was placed.

It has been pointed out by several electrical men, and particularly by Dr. Giuseppe Musso, the well-known consulting electrical engineer of New York City, that quite possibly the points at which to apply these transmitting and receiving coils, or other forms of apparatus, is not about the head at all, but at some other vulnerable point or points on the body which would have to be found by experiment, and also in consideration of the fact that these more vulnerable points have the strongest effect on the control of the electric charge on the body. He also has said that in thought transference it has been invariably noted that best results are obtained between two persons having a strong affection for each other, which in another sense might be considered as two minds "in tune" or syntony.

Are you a regular reader? It will pay you to become one!

Electric Toys That Respond To The Voice

ANOTHER novelty for amusing children has arrived in the form of toys, voice operated by electricity. These new toys afford entertainment for

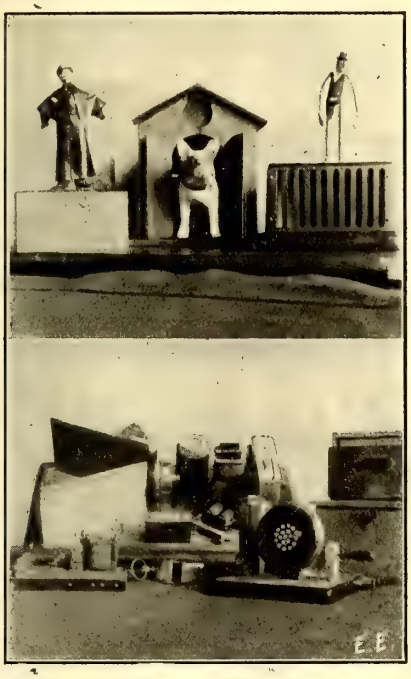

Fig. 1 (Above) Portrays Three Electric Toys Controllable by "Voice." Fig. 3, (Below) Depicts Interior of Toys.

pleasure-loving youngsters as well as the adult, and are operated by sound waves actuating a delicate microphone, by which the various movements of the toy are incited.

The toys herewith illustrated are the results of continuous labor by Mr. H. Christian Berger, the inventor and originator of the submarine wireless system, which was described at length in the August issue of this magazine. These toys in order to operate require solely the human voice or a common whistle. Nor is it necessary to be near the toys; they will operate, for instance, if the whistle is blown 30 feet distant from the apparatus with a result

Fig. 5. At Left Shows Voice Controlled Gun. At Right a Disappearing Satan's Head.

that is as uncanny as it is startling in its novelty.

Fig. 1 represents a group of three electric toys. The one at the left is a *policeman,* enclosed in a case; who, when a certain sound is produced, suddenly jumps up from the case. In the center is a small *dog,* resting in his miniature kennel, the doors of which are closed. As soon as an ordinary whistle is blown the doors open and the little animal jumps out so suddenly that one is almost taken aback at the unexpectedness of his appearance. The third and most interesting is the *dancing coon* seen at the right. This *coon* will perform all kinds of dances as long as the proper tune or sound is produced.

The grate opening in the front of the cabinet is the collector of the sounds which are caused to act on the microphone.

Fig. 2 depicts a schematic diagram of the apparatus used within the dancing doll's abode. M is a microphone connected in series with a battery and relay D, operating a pair of electro-magnets H, which are connected in series with a vibrator L. In operation, when the sound waves strike the microphone M, the resistance of same varies, and the current strength in the magnet D decreases. The armature closes the contacts, X Y, energizing the magnet H, and short-circuit-

Fig. 4. A Whistle Will Fire This Miniature Field Cannon.

ing the microphone. The excitation of the magnet D then again increases and attracts its armature, consequently varying the the fluctuations in electro-magnet H, which in turn operates the doll at Fig. 1, whose hands and feet are made of coiled steel springs. This metal is attracted by magnetism, generated by the electro-magnet H. Also the shoes may be of iron so as to be acted upon by the electro-magnet.

The interior view of these toys is shown at Fig. 3. The apparatus on the right is a microphone relay, operating any electrical device just by the production of *sound,* acting upon the microphone.

The larger instrument, seen in the background of the photograph, is the exact apparatus used in the electric *dancing coon*; while the one towards the left is an automatic controlling relay. The whistle here shown is used as the sound actuator of these novel toys.

Miniature "field guns" are also operated by sound waves, and Fig. 4 illustrates such a gun, which is electrically fired and operated by sounds produced from the whistle shown at the extreme right, near the wagon containing the ordinary instruments used for operating the other toys.

Two very interesting toys are portrayed in Fig. 5; the one at the left, representing

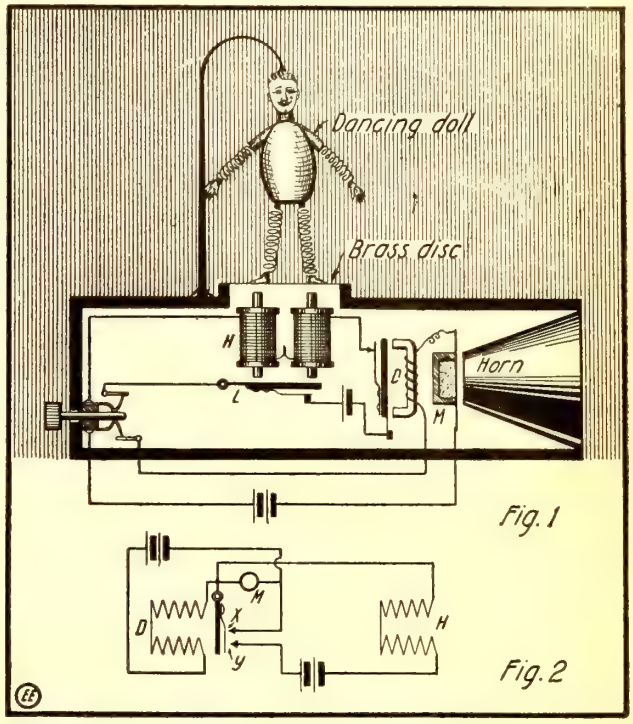

Fig. 2. Diagram of "Dancing Doll" Apparatus Subject to Voice Control.

a device for throwing a "ball" into the air, while the other is a "Satan's Head" concealed in the chimney of the small house, as perceived, who immediately appears at the sound of a voice.

A very suitable toy for Christmas time is illustrated at Fig. 6. This is a tree decorated with miniature electric bulbs, connected to a circuit, including a microphone and batteries, as seen at the left. The lamps on the tree are operated by the microphone whenever sounds are produced by the blowing of the whistle seen in the foreground.

These extremely interesting electric toys

Fig. 6. Electric Lights on Xmas Tree Controllable by Whistle and Microphonic Relay.

mark a distinct advance in the realm of amusement apparatus, and it seems this principle could be well applied further.

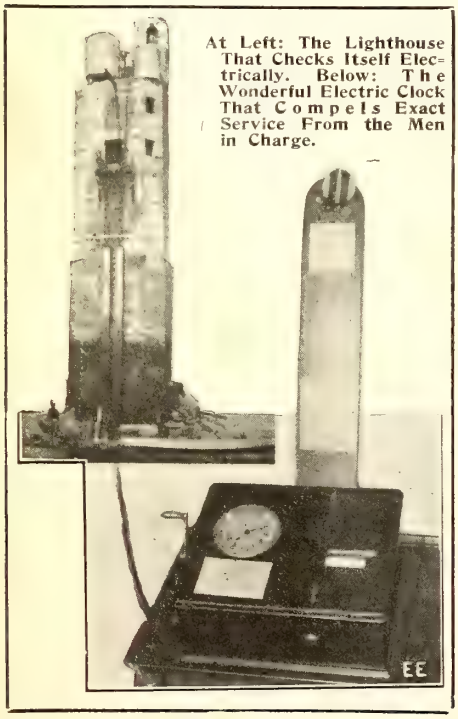
A LIGHTHOUSE OPERATED AND CHECKED BY ELECTRICITY.

By Edwin O. Catford.

WHEREVER men are placed in an isolated situation with long continued responsibilities the need for some kind of check or inspection becomes evident. Personal inspection in such cases is necessarily infrequent and therefore inefficient. The men concerned, if they are competent and keen on their work, will welcome any device which is an aid to efficiency.

Some devices of the writer's in use at Platte Fougère Lighthouse Station, Guernsey, England, may be of interest, since they constitute the equivalent to an hourly inspection day and night, year in and year out, with the advantage of automatic and therefore absolutely impartial working.

A clock is provided with a roll of paper attached on which the man on duty records his signature each hour. This clock is also used to note the time of starting and stopping the "fog signal," and in the event of any dispute arising in regard to these times the clock record proves invaluable.



Several electric attachments have been added by the author to this clock.

First, some contacts insure that if the man on duty has not "signed on" the clock will set three electric alarm bells ringing at 20 minutes past the hour.

These bells are situated, respectively, in the engine room and in each of two dwelling houses, so that they serve to call out the keeper who is off duty. Thus this clock may truly be said to be equal to the provision of an hourly inspection day and night.

Should the man on duty meet with an accident during the night, which is always possible with dangerous machinery as used for fog signaling, without these clock attachments he would simply lie until morning with the added probability, almost amounting to certainty, that the machinery also would come to a standstill with the fog still remaining.

The clock insures that should an accident occur which disables the man on duty so that he cannot sign at the clock, at 20 minutes after the next hour the alarm will automatically be raised and the second man called out to duty. Thus by calling aid the clock might save a man's life.

At Left: The Lighthouse That Checks Itself Electrically. Below: The Wonderful Electric Clock That Compels Exact Service From the Men in Charge.

The clock is also a complete safeguard against sleepfulness at night, for which felony it provides instant punishment.

The writer can testify that it is a most disagreeable experience to hear the bells ring out at night and to realize that the whole of your own household, as well as that of your neighbor, has been aroused from sleep by one's own delinquency.

In order to give an indication that the electric alarm attachment is in constant order, it is so arranged that each bell gives a single stroke every hour.

This notifies that all is in order and incidentally shows in both houses that the clock connections have not been tampered with. Twenty minutes later the alarm bells ring out in earnest, unless in the interval the man on duty has "signed on" at the clock.

The recording clock with the author's electric attachment compels the lifting of the clock handle once every hour.

Seizing on this fact it was next arranged that by means of further electric contacts attached to the handle a testing current passes out to the lighthouse through one wire of the cable, returning by another wire, each time the clock is operated; that is, once every hour day and night.

This provides a test for continuity of the cable, it also indicates that the electric lamps and electric lighting circuit are intact and, further, by means of a special pressure gauge on the lighthouse it gives warning ashore when less than a fortnight's supply of acetylene remains for the light.

Double pole contacts are used so that no battery leakage can take place through the cable when the test is not being made. Those who know the insidious electrolytic troubles liable to introduce themselves wherever any continuous leakage of current, however small, becomes possible will appreciate this point.

These indications are useful at all times, but they are doubly appreciated on days and nights when the sea dashes with terrible fury on land and lighthouse, and it is evident that many days must elapse before a visit to the lighthouse will become possible.

To be able then, simply by lifting a handle (in safety) ashore, to obtain assurance as to the condition of affairs on the storm-swept lighthouse is no small gain.

ELECTRIC DENTAL SIGN THAT DEMONSTRATES "BEFORE" AND "AFTER" EFFECTS.

A very pretentious electric sign erected in New York City for a large dental parlor, as shown in illustration and the small insert picture, shows the countenance as it is supposed to appear before visiting the dentist, and the larger photo the satisfied smile and improved appearance of the teeth after taking treatment.

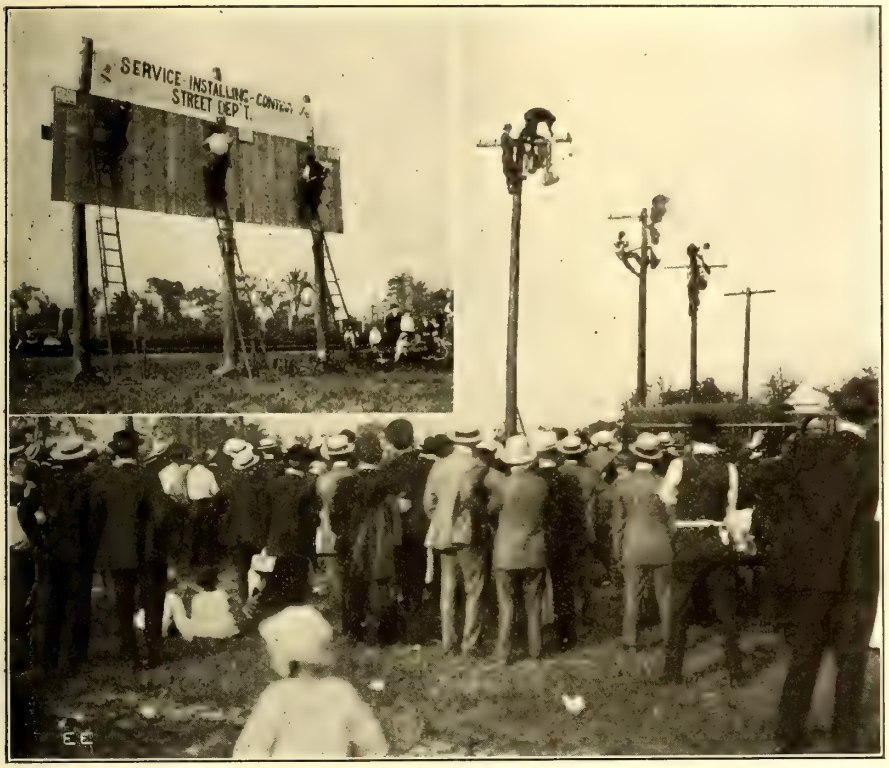
This sign is a large affair and is made entirely of opal glass, which is lighted up from the interior of the sign by means of electric bulbs properly arranged. These are operated by a motor driven flasher, so that the two different faces appear alternately. The features of the countenance where the two teeth are shown missing is also caused to change, so that the general appearance is one of sadness or pain.

This novel electric sign is one of the well-known *Federal* line, and attracts unusual interest in the endless crowds that throng the "Gay White Way" of the Old Town.

Such electric signs as here described are a great improvement upon those of a few years ago, to be sure.

Top View Shows "Before" Appearance of Face, and Lower Illustration, "After" Effect, Produced in New Electric Sign.

LIMIT TUCKERTON WIRELESS.



None but Government and Embassy messages will be sent by way of the Tuckerton wireless station until further notice. Messages for Germany and Austria must be forwarded by way of Sayville at the same ra es.

AUTHORS! ATTENTION!

What ideas have you regarding the construction and operation of wireless and electrical apparatus? Why not write up these ideas and experiments for the benefit of the *Electrical Experimenter* readers and thus help yourself and your fellow-worker at the same time. We are pleased to receive contributions of the above character with plain ordinary sketches or photographs and pay regular rates for all such matter published in these columns. Address all communications to the Editor.

Installing A Complete Electric Service in 15 Minutes

As one of the features of the annual field day and outing of the Commonwealth Edison Company, of Chicago, service gangs from each of the company's three overhead districts competed in a service installation contest. The crew representing each district had previously been selected by elimination contests conducted in regular service-installation work during the two weeks preceding the field day.

Insert Above Shows Service Gangs Installing Apparatus in Prize Contest. Lower View Portrays Transformer and Pole Work Contest.

Before the day of the final competition a pole line carrying primary wires on single arms was erected on the field. A platform on which three sections of brick wall were mounted was also erected at a distance of 75 feet from the poles. Above it were placed three regular service outlets connected to groups of lamps. Each gang consisted of a foreman, two linemen and a groundman. The foremen were not allowed to do any work. Sitting in their trucks, which were loaded with standard tools and equipment, the men awaited the signal to start.

The rules of the contest required each crew to do the following work: Cut a gain and bore a hole for a buck arm on the pole; install the buck arm with braces and primary cut-outs; hang a transformer; connect the transformer to the primary circuit and to the service drop; install a bracket with three Pierce bolts on the brick wall; run a 75-foot two-wire service from the pole to the bracket, and connect the service to the outlets. All joints were to be soldered and properly taped. The last thing to be done was to insert the primary plugs to light the lamps above the outlets, indicating that the work had been completed. Any failure to complete the job according to the company's standard practice was to result in a penalty equal to three times the time it would ordinarily take to do that part of the work. Any violation of the company's safety rules was to result in disqualifying the whole gang. Three judges with stop watches took the time and observed the work as it proceeded.

In addition to the prize money offered to the winner of this contest as one of the regular field days events, an added bonus of two cents for each second under 20 minutes was provided for each man in the winning crew.

None of the gangs were disqualified for violating the company's safety rules. The winning crew was, however, penalized 15 seconds for spilling solder.

YACHT'S "MONEL" METAL HULL RUINED BY ELECTROLYSIS.

Alexander Smith Cochran's magnificent schooner yacht "Sea Call," after being in commission only six weeks, is now being broken up for scrap in the yards of her builders at Neponset, Mass.

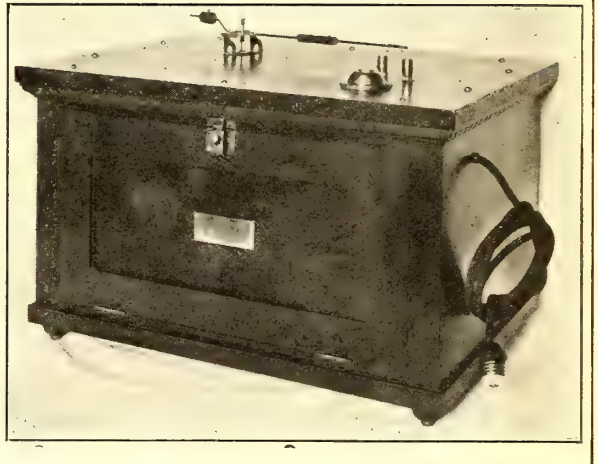
The "Sea Call" is a splendid sailing yacht with auxiliary gasoline engine. She is being knocked to pieces on account of the disintegration of her bottom through electrical action.

The electrolysis which has damaged the bottom of the boat is said to be due to the use of a steel skeleton and a bottom of monel metal, an expensive alloy composed of, roughly, two parts nickel to one part copper, with small additions of other metals.

It was understood that electrolysis affected the steel skeleton and not the plates of the bottom, but reports from Neponset say that, while the action did start around the stem and stern posts, which are of steel, it resulted in the deterioration of the monel into "a chalky substance." It is said that there are evidences of deterioration in the monel plates of the bottom, but the suggestion has been made that this is only discoloration due to the electrolysis of the steel.

AN ELECTRIC BACTERIOLOGICAL INCUBATOR.

By Frank C. Perkins.

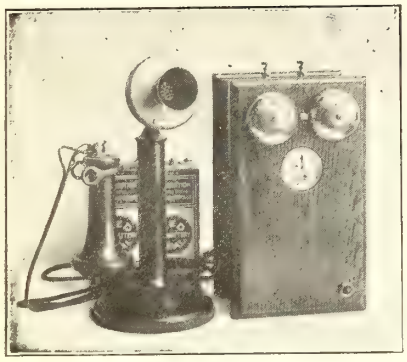


The accompanying illustration shows a most interesting electric bacteriological incubator said to be in advance of the gas-heated devices now generally used on account of the extremely uniform temperature regulation provided.

It was developed at Salt Lake City, Utah, and is so designed that when once adjusted to the desired temperature, it is claimed, it will operate for days at a time without any attention. The incubator is heated with electric resistance coils in the top of the device.

It may be stated that there is a wafer thermostat inside the machine which expands with rise in temperature and pushes a piston stem which raises and lowers a balanced lever arm carrying two electric contact points. These two contact points dip in mercury cups, which are connected in series with one side of the circuit. When the temperature inside the incubator reaches the desired point the contact point is lifted out of the mercury, thus opening the circuit. When the temperature falls just a small fraction of a degree the contact points are lowered back in the mercury and the circuit is closed, thus bringing the machine back to the proper temperature.

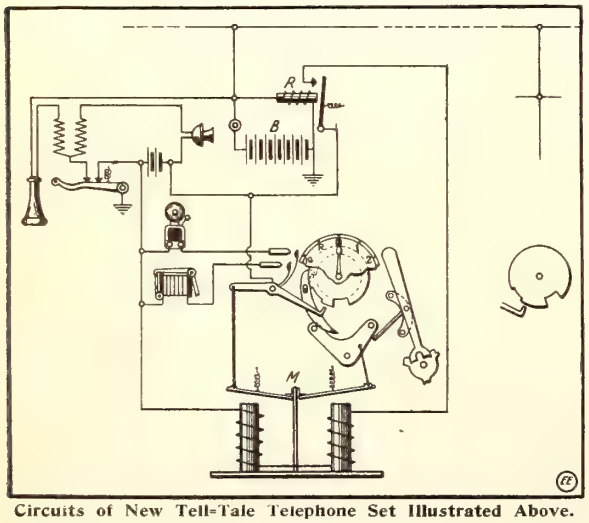
It is held that a variation of less than 0.1 degree will cause the device to operate and to open or close the circuit. Temperature adjustment is obtained by means of a small screw. The incubator consists of a double-walled box having a 0.5-inch air space between the outer and inner walls. The box is finished in mahogany and is equipped with double doors, the inner door having a glass panel so that the contents of the machine may be readily inspected without opening the door.



By means of the button seen on top of the machine a miniature lamp inside the incubator can be turned on. The maximum input into the machine is 50 watts, and the average input per hour is about 25 watts. It measures 8 inches in width and 10 inches in height, with a length of 16 inches.

An Automatically Compensated Bacteria Incubator With Electric Heating Coils.

TELEPHONE THAT TELLS WHO CALLED WHILE YOU WERE OUT.



On a single-wire, par -line telephone circuit near Constableville, N. Y., each subscriber is provided with a telephone in-

Novel Telephone Set That Tells Who "Called" While You Were Out.

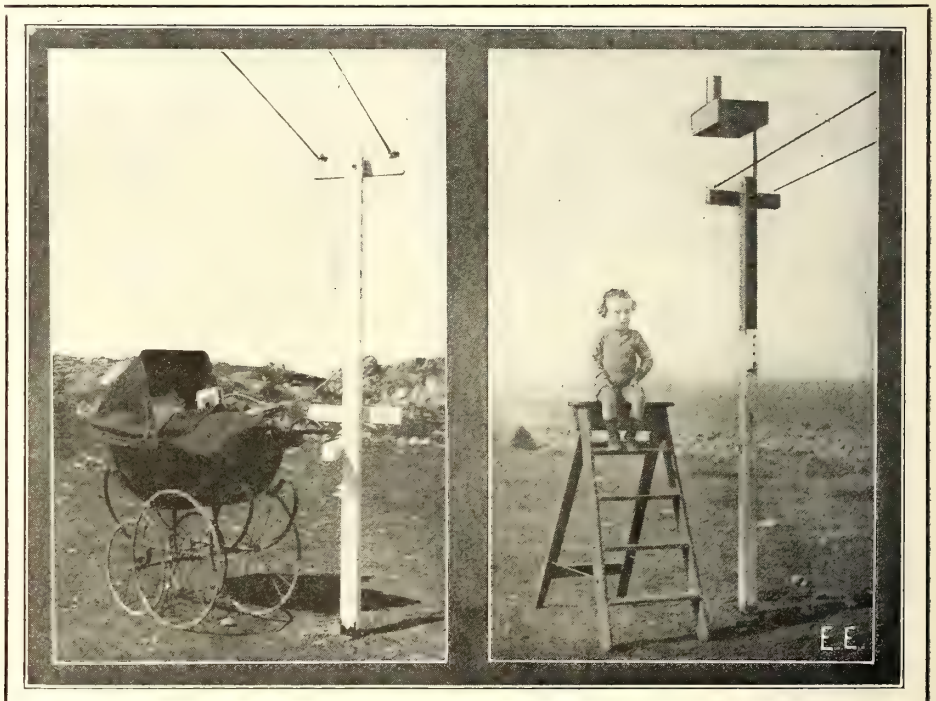
strument equipped not only with a selective ringing attachment, but also with a device to inform the subscriber who, if anyone, called in his absence. The instruments were constructed under specifications covered in a patent issued to P. G. Bernholtz, Constableville, N. Y. They differ from the standard ground-return telephone in that a special battery has been added to the local circuit and a visual signal or drop, as well as a bell, has been arranged to operate through an especially designed selective-signaling mechanism.

To call a subscriber on a line equipped with these instruments it is necessary to close the special battery (*B*) circuit through the push-button. The special battery operating all relays (*R*) on the line unlocks all instruments. The indicator then moves automatically to the desired number, and when the line is again energized the selective-signaling apparatus in the called subscriber's instrument rings the bell and operates the visual signal or drop. Other instruments return to their normal positions. If it so happens that the called party is not within earshot of the bell, he notes on his return that the visual signal has been operated. He then places his indicator on *R* and energizes the line by means of the special battery, ringing all bells on the line, but failing to actuate any of the visual signals because the indicator was set at position *R*. Hearing this call and observing that the visual signal has not been disturbed, all subscribers understand the signal, and only the one who previously called and failed to obtain the individual with whom he desired to communicate is supposed to answer.

Circuits of New Tell-Tale Telephone Set Illustrated Above.

A Telephonic "Nursemaid" and a Bird Alarm

The accompanying illustration shows the application of the telephone as a nursemaid as devised by an ingenious Englishman. Open air life is undoubtedly best for babies, who indeed, showing a wisdom beyond their years, sleep at once out of doors after strenuously refusing to sleep inside the house. The difficulty has been that where there is no housemaid the busy mother cannot spare time to be constantly outside looking after baby.



The photograph shows the details of a plan successfully employed by Edwin Catford, the engineer-in-charge at Platte Fougeré lighthouse, Guernsey, where the baby carriage is provided with a cigar box containing a telephone transmitter and a small clock. Wires running up to the house, 20 yards away, enable the mother in the intervals of work to listen for baby's cry; if at the table and during meals it is easy to listen continuously.

A clock attachment was also provided. "No news is good news" does very well as a popular saying, but the electrical engineer knows better, for *no news* often means a hitch in the means of communication. In this case the clock is added so that the sound of its ticking may indicate that the telephone is transmitting sounds correctly. The device proved entirely successful through baby's first year. Not only was baby's cry distinctly heard, but also the comments of persons not knowing of the telephone in the cigar box who approach the spot on the common where baby sleeps. A rain alarm was also evolved to give warning by causing an electric bell to ring should a shower come on.

The second illustration shows an interesting birds' telephone, devised also by E. O. Catford for the benefit of his little son.

As cats kept birds at a distance from the house so that this little boy could not have the pleasure of watching them feed from crumbs thrown out, a cat-proof tray was therefore set up in front of the windows at some distance from the house and here robins, finches and other birds came to feed.

It is of interest to note that the telephone transmitter was then added, so that when the birds sang they could be listened to in the house. Doubtless a better plan would have been to conceal telephone transmitters among the branches of bird-frequented trees, but here there were no trees available. The transmitter in use is the ordinary kind used for speech and is protected from rain by an inverted cocoa tin, well painted, open at the lower end to freely admit sound. After months of this outdoor use the telephone remained in perfect condition.

A Telephone Nurse Maid (at Left) and an Electric Bird Alarm (at Right).

TELEPHONE NEW POLICE AID.

Police Commissioner Arthur Woods announced recently that the New York Telephone Co. will co-operate with the police department in capturing criminals. The territory within 100 miles of New York has been divided into seven zones, and as soon as headquarters notifies the telephone company descriptions of men wanted will be sent to all the zones.

Within a few minutes all chiefs of police, sheriffs, constables and railroad station men can be on the lookout.

WIRELESS AND PIGEONS.

Recent experience has tended to show that carrier pigeons and other birds of passage are guided by magnetic currents. W. A. Thauzies, a French student of pigeons, has noted that on two occasions when pigeon flights were unsatisfactory magnetic storms were occurring; and the flights of these birds have been becoming often uncertain and erratic since wireless telegraphy came into extensive use.

An Electro-Magnetic Nail-Packing Machine

By Frank C. Perkins

THE accompanying illustration, Fig. 1, shows an interesting electro-magnetic nail-packing machine developed at Zurich, Switzerland, while Fig. 2 shows the scheme of packing and indicates the saving accomplished with this orderly method of doing the work as devised by Otto Gamper. Note the new style packages at the right of Fig. 2, containing as many nails as the keg in the center.

One type of this electro-magnetic nail-packing machine is suitable for paralleling and packing nails 2 to 6 inches long, and a special construction for nails 2 to 10 inches long. Until recently, in spite of the fact that for a long time in the nail industry there has been felt the need of a really practical paralleling and packing machine, no one has succeeded in designing an apparatus capable of performing the time-wasting operations of paralleling and packing of nails in a thoroughly satisfactory manner.

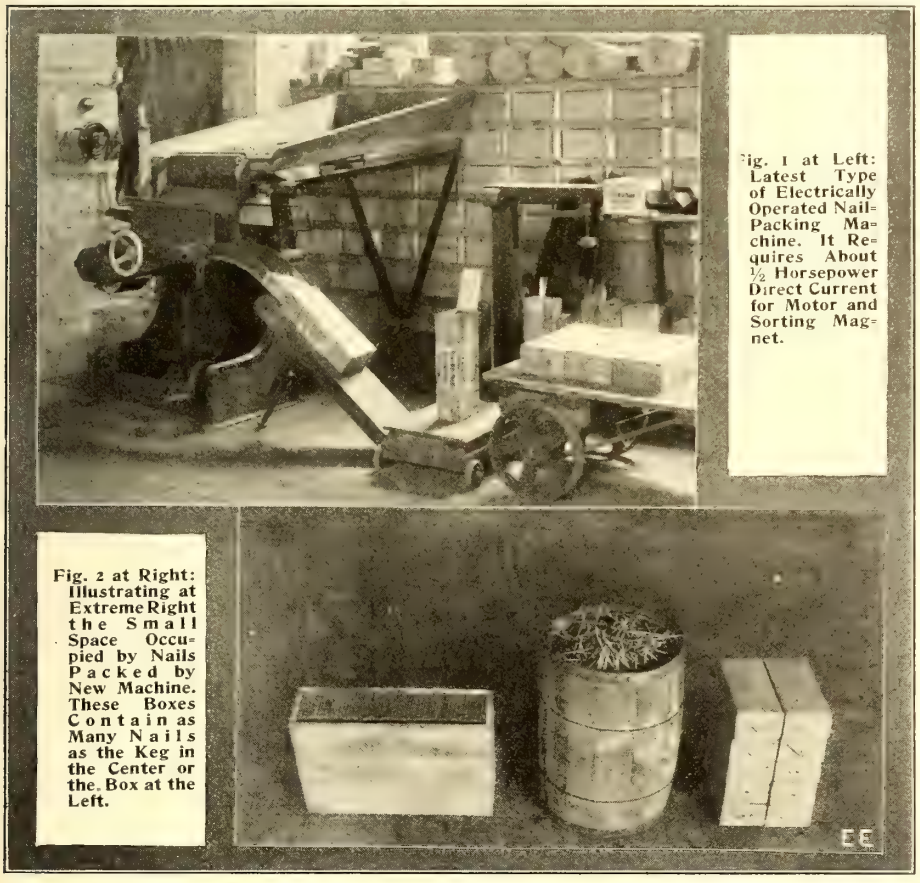


Fig. 1 at Left: Latest Type of Electrically Operated Nail-Packing Machine. It Requires About ½ Horsepower Direct Current for Motor and Sorting Magnet.

Fig. 2 at Right: Illustrating at Extreme Right the Small Space Occupied by Nails Packed by New Machine. These Boxes Contain as Many Nails as the Keg in the Center or the Box at the Left.

This packing machine is based on the principle well known to every electrician, that all linear iron objects, as soon as they are brought into a homogeneous magnetic field, must adjust themselves automatically, under the influence of the magnetizing current, in the direction of the magnetic lines of force, which, as is well known, always run parallel to each other. This being so, it, of course, follows that this machine is not only suited for the paralleling and filling of nails, but that it can be equally well used for packing all magnetically excitable linear objects, such as wire rods, coach screws, hairpins, pens and knife blades.

It will be noted that the machine consists of two main parts, a paralleling mechanism and a feed trough above it, into which a shaking device is fitted. The objects to be packed are emptied into the feed trough in quantities of about 10 cwt., whence through the action of the shaking device they glide gradually into the paralleling mechanism and then, while still falling, are drawn in the direction of the magnetic lines of force. As a consequence they are paralleled in a mathematically exact manner. The objects, thus arranged in parallel and held suspended in the paralleling mechanism by the lines of force, are by means of a lever, which simultaneously cuts out the magnetizing current, pressed into a tray which is fixed between the two magnet poles. This sheet iron tray swings downward, and from it the objects get emptied by a slight jerk into the paper packet, the mouth of which is placed over the end of the tray by the operative in order to receive them.

It is stated that this simple working cycle, making it possible for a girl to attend to the machine, can be repeated so rapidly that one workgirl trained to a certain extent for such work can in one hour deal with ordinary nails of No. 6-6-inch equal to 1,700 to 2,400 pounds in packets of 10 pounds each and No. 10-3½-inch equal to 1,300 to 1,600 pounds, in packets of 7 pounds each, while moulders' nails are handled at the rate of No. 15-6-inch equal to 600 to 800 pounds in packets of 10 pounds each and nearly the same number of packets of 1½-inch, 2-inch, 3-inch and 4-inch nails.

It is claimed that the above quantities represent the following values when compared with those dealt with by hand: Ordinary nails, 4 to 5 times the quantity dealt with by hand, and moulders' nails, 10 to 15 times the quantity dealt with by hand, involving, of course, a corresponding saving in wages.

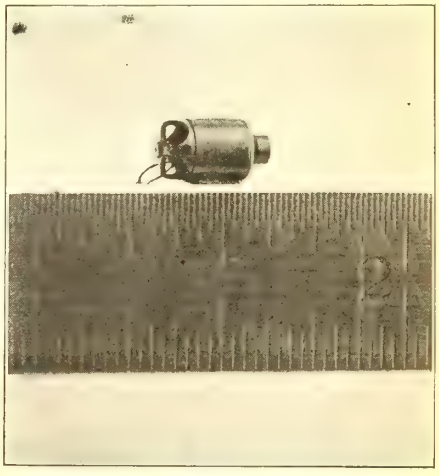
WIRELESS ON MOTORCYCLE TO PACIFIC COAST.

By A. J. Geiss.



Mr. and Mrs. Wengatz, of Albany, N. Y., passed through Toledo, O., on their way to the Pacific Coast on July 20 last. Mr. Wengatz will be joined later on by Fred Wallace, also of Albany. Their outfit consists of a Dayton motorcycle with side car and trailer. They carry a complete wireless telegraph outfit, and Mr. Wallace, who is a licensed radio operator, will communicate with wireless stations at distant points along their route. They expect to reach the coast in three months, and if the war ends this fall the trio expects to make it a tour of the world.

Wireless Set on Motorcycle Bound for Pacific Coast.

THE SMALLEST ELECTRIC MOTOR.

A motor recently completed by Ivan T. Nedland, a jeweler of North Dakota, weighs only 5.5 grains and is said to be the smallest motor in the world. Its commutator, which measures 0.045 inch in diameter, is made up of four gold segments insulated from each other with mica. No glue or cement was used in its construction. The shaft on which the commutator is mounted is made of steel and is 0.009 inch in diameter. Fiber insulation is used between the commutator and the shaft. The tiny armature, 0.09 inch in diameter, has four pole pieces and is wound with No. 40 silk-covered copper wire. The weight of the revolving part is 1.25 grains. Between the armature and the yoke two field coils are provided. The silver brushes measure 0.012 inch in diameter and are held against the commutator by springs 0.004 inch in diameter. In overall dimensions the motor measures 19/64 inch long and 11/64 inch high. All visible parts are finished in Roman gold. When connected to a small flashlight battery the motor runs at a very high speed.

Said to be the Smallest Electric Motor in the World. It Measures 19/64 Inch Long.

ELECTRICITY ON GERMAN SUBMARINES.

Electricity plays the leading role in the operation and navigation of the modern submarine, the terror of the undersea. The illustration herewith shows the compactly arranged electrical and gasoline engine unit installed in a modern German submarine, half of the hull of the boat being left off, so as to show a sectional view. Those interested would do well to peruse an exhaustive article entitled "Electricity, the Power Behind the Submarine Boat," which appeared in the *July*, 1915, issue of this journal, wherein all of the important functions of the electrical installation of modern submarines are fully discussed and illustrated.

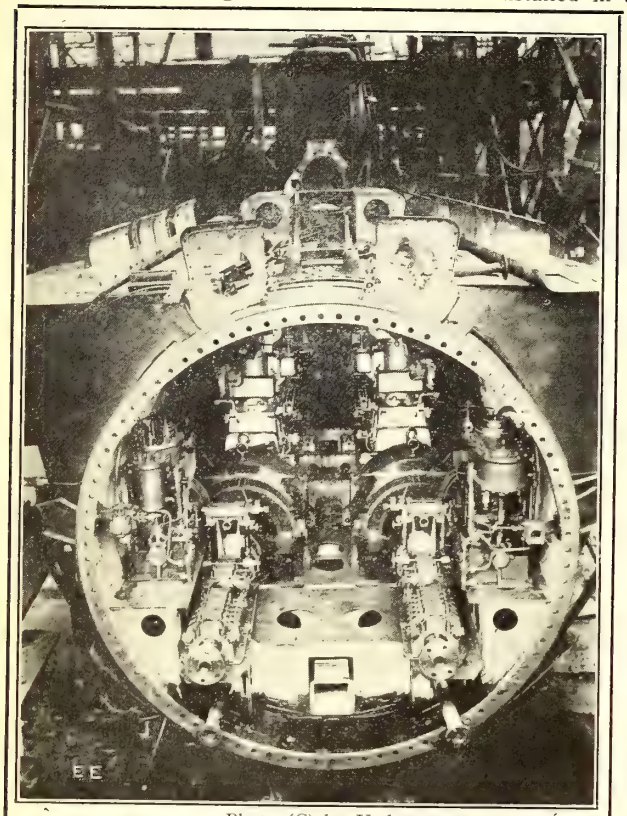


Photo (C) by Underwood & Underwood.

Remarkable Interior View of a German Submarine, Showing the Powerful Electric Motors.

The submarine of to-day is one of the most highly perfected mechanisms ever wrought by the hand of man, and enables the crew of same to sink beneath the surface of the sea and to cruise in this fashion, submerged entirely from sight, for a distance of 100 miles or more, without coming to the surface for air. Special air purifiers and regenerators are provided. Powerful electric storage batteries drive the motors connected to the propellers of the boat when under water. On the surface the gasoline engines are generally used for cruising and, simultaneously, these also drive the motors as dynamos, thus generating current for charging the storage batteries. These boats carry wireless installations of considerable range, as well as the very latest types of submarine signaling devices, operating on *etheric* as well as on the *sound wave* principle, whereby telegraphic signals can be transmitted from one submarine to another through the water and also from a submarine to its mother ship or tender.

The latest vessels of this class have a large cruising range of several thousand miles before returning to their base, and they can be submerged and raised from the sub-surface very rapidly, owing to the ingenious and highly perfected electrical control arrangements provided and which are all quickly available by means of a concentrated group of push buttons at the commander's side, when he is scanning the sea through the periscope for possible victims.

ELECRIC LIGHTING AT PANAMA CANAL.

Our illustration shows the beautiful electrical illumination of the Panama Canal at the Pedro Miguel Locks. The powerful electric lamps are placed on tall concrete columns. The electric current utilized for these lamps is generated at the Gatun Spillway. These ornate lamps serve a double purpose. They permit the passing of the vessels through the canal at night and also make it easier to guard the locks from an attack by an enemy in time of war.

Efficient Electric Lighting Will Help to Guard the Panama Canal.

EDISON'S SECRET.

Thomas A. Edison says new methods of slaughter are in their infancy to-day, but that he cannot find it within himself to work along any line looking to the destruction of life.

He says the possibilities of chemistry and electricity have hardly yet been touched upon in modern warfare, that he knows of more deadly things than the gas bomb that he could invent, "but I can't get myself to work on any such stuff as that. I don't want to destroy life; I want to make the world a better place to live in."

It's a beautiful thought of the great inventor. But maybe in the secret he holds is the awful something that would compel world peace.

HOW "PUSSY" RINGS THE DOOR BELL.

An interesting photograph is shown herewith of an intellectual *cat* owned by Mr. E. L. Catford, of Guernsey (England). The feline announces his desire to enter the kitchen door by sitting on the small shelf observed in the photo. When the cat sits on the shelf an electrical contact spring is closed, which rings the electric bell on the interior of the house.

"Pussy" Gains Admittance by Hopping on this Electric Alarm Shelf.

With very little training this particular member of the cat family soon learned to hop on the shelf whenever it desired to come in, especially during storms, and now makes regular use of the shelf, no matter what kind of weather ensues.

AN ELECTRO-MAGNETIC NAIL-PACKING MACHINE.

(*Continued from page 259.*)

It is pointed out that taking the average reduction in volume to be 50 per cent. for nails arranged in parallel, as compared with such nails shaken loosely into boxes, kegs or barrels, the advantages in connection with packing in boxes and barrels include 30 to 45 per cent. saving of wood through using smaller boxes, kegs or barrels and 10 to 15 per cent. saving in delivery charges through reduced tare, also 40 to 50 per cent. saving in storage.

It is maintained that by using this machine for box filling one obtains 50 per cent. reduction of space with ordinary nails and 70 per cent. reduction of space with moulders' nails, also a 30-45 per cent. saving of wood by using smaller boxes and 10-15 per cent. saving in delivery charges owing to reduced tare.

The electric drive of the machine is of interest. It requires about ½ hp., either from a high-speed line shaft, or where electric driving power is available from a motor erected on the machine. This latter drive is to be preferred because the packing machine is made independent of the line shaft.

The electric current required is small. The feeding of the magnet coils, the current for which amounts to about 1.5 kw. hours per day, takes place by direct connection to an existing direct current supply line having a tension of 110 to 220 volts. Where no direct but alternating current energy is available the necessary direct current is generated by a small converter. If there is no electric energy available the same is generated by a direct current generator mounted on the packing machine. The machine is 5 feet high and takes up a space 6 feet 8 inches to 4 feet 4 inches and its weight is about 13 cwt.

OUR NOVEMBER ISSUE

will contain a wonderful article on "Selenium." You cannot possibly afford to miss it.

NEW SCALE FOR WEIGHING LAMP FILAMENTS.

A precision torsion balance of special design is shown in the illustration herewith. This device is used in general for

Precision Torsion Balance for Weighing Lamp Filaments.

weighing extremely light bodies, but its principal application is in connection with the incandescent lamp industry. In the manufacture of incandescent lamps it is essential that the filament possess certain characteristics, one of which is that its length and, therefore, its weight shall be uniform within certain predetermined limits. While high accuracy is, of course, requisite, the instrument must at the same time be rugged; and these two features are embodied in this instrument.

In use the balance is set on a vibrationless table and carefully leveled by means of the leveling screw and plumb-bob. The *filament* is then hung on the hook which is shown projecting from the right side of the case. The moving element is then freed by manipulating the lever which projects through the bottom of the case just to the left of the vertical support. The large pointer is moved slowly across the scale until the small pointer shown adjacent to the hook comes to the zero point. The indication of the large pointer is then that of the weight of the filament which is being tested.

In actual use the manually operated pointer is set at the presumed weight of the filament, and the position of the small pointer indicates whether the filament is above or below that weight or is exactly the same. These balances are in general use in practically all the lamp factories in this country.

HOW ELECTRICITY GROWS IN SOUTH.

In 10 years South Carolina's jump in consuming electricity by the kilowatt-hour was from 18,000,000 to 356,000,000. This is the largest proportionate gain of any State in the country. New York leads in output of electrical energy, more than 2,000,000,000 kilowatt-hours being used in 1915.

Marconi Heads Wireless Corps of Italian Army.

Signor Guglielmo Marconi, the famous Italian wireless inventor, is seen in our photograph herewith at the key of a large English wireless station located at London. This was taken on his recent trip to England, where he went on special business regarding some new wireless sets he has recently developed for the use of the soldiers in the field and which are said to be small enough and efficient enough to permit officers obtaining information while on the battlefield without utilizing the more cumbersome "trunk" sets making up the regular radio equipment of the signal corps division.

Signor Marconi is at the head of the wireless division of the Italian army and navy and, needless to say, their equipment will be second to none in the great European war.

This master genius has had wonderful opportunities to test out wireless telegraphy over vast distances and with all kinds of apparatus in a more practical way perhaps than has been possible for any other engineer or scientist of our day. It has not always been so, however, as many of our greatest inventors and scientists, notably Hertz, have unfortunately never seen their ideas commercialized to any such extent as has Signor Marconi. The Marconi corporations today operate over the greatest ranges and utilize the very latest apparatus known to the art. Marconi is to Italy what Edison is to the United States. He has rendered a service to mankind that will not be forgotten for centuries to come.

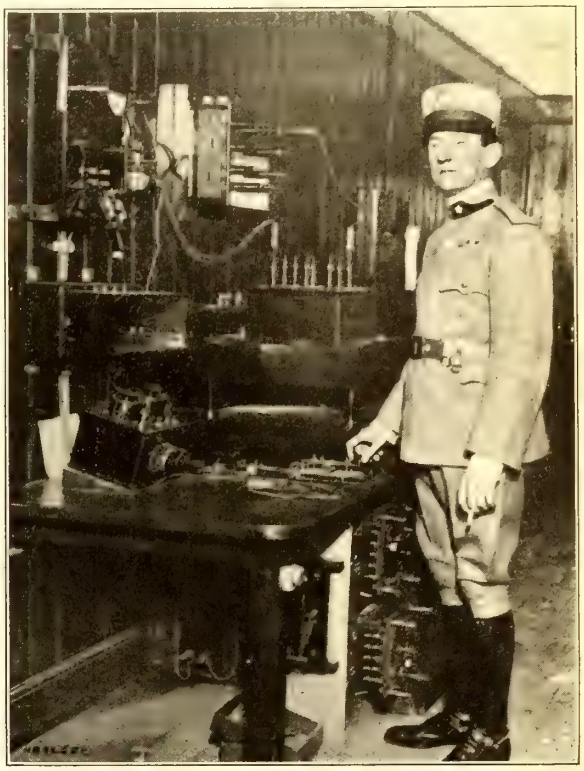

Photo (C) by Underwood & Underwood.

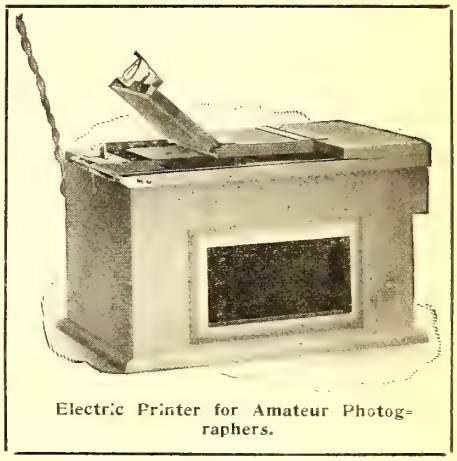
Signor Marconi at the Key of a British Radio Station. A Recent Picture.

COMPLIMENTS ARLINGTON WIRELESS.

Captain Gowan, master of the Johnston liner "Swanmore," at Baltimore, pays a high compliment to the perfect working of the Arlington wireless station. Captain Gowan states that when 1,400 miles off the American coast he is able to catch with great clearness the noon-time signal sent out from Arlington. So clear does the signal come that each tick of it can be heard distinctly. Beyond 1,400 miles the time from the Eiffel tower at Paris is picked up, but it is not clear and often leaves him in doubt about the real time sent out. This superiority of the American station, Captain Gowan said, was not simply at times, but was always so satisfactory that he rated his chronometers by it without a doubt as to accuracy.



A NEW ELECTRIC PHOTO PRINTER.
